12.123 In making computer chips, a $4.00-\mathrm{kg}$ cylindrical ingot of ultrapure n-type doped silicon that is 5.20 inches in diameter is sliced into wafers $1.12 \times 10^{-4} \mathrm{~m}$ thick.
(a) Assuming no waste, how many wafers can be made?
(b) What is the mass of a wafer $\left(d\right.$ of $\mathrm{Si}=2.34 \mathrm{~g} / \mathrm{cm}^{3} ; V$ of a cylinder $=\pi r^{2} h$ )?
(c) A key step in making p-n junctions for the chip is chemical removal of the oxide layer on the wafer through treatment with gaseous HF. Write a balanced equation for this reaction.
(d) If $0.750 \%$ of the Si atoms are removed during the treatment in part (c), how many moles of HF are required per wafer, assuming $100 \%$ reaction yield?
12.124 Methyl salicylate, $\mathrm{C}_{8} \mathrm{H}_{8} \mathrm{O}_{3}$, the odorous constituent of oil of wintergreen, has a vapor pressure of 1.00 torr at $54.3^{\circ} \mathrm{C}$ and 10.0 torr at $95.3^{\circ} \mathrm{C}$. (a) What is its vapor pressure at $25^{\circ} \mathrm{C}$ ? (b) What is the minimum number of liters of air that must pass over a sample of the compound at $25^{\circ} \mathrm{C}$ to vaporize 1.0 mg of it? 12.125 Mercury ( Hg ) vapor is toxic and readily absorbed from the lungs. At $20 .{ }^{\circ} \mathrm{C}$, mercury ( $\left.\Delta H_{\text {vap }}=59.1 \mathrm{~kJ} / \mathrm{mol}\right)$ has a vapor pressure of $1.20 \times 10^{-3}$ torr, which is high enough to be hazardous. To reduce the danger to workers in processing plants, Hg is cooled to lower its vapor pressure. At what temperature would the vapor pressure of Hg be at the safer level of $5.0 \times 10^{-5}$ torr?
12.126 Polytetrafluoroethylene (Teflon) has a repeat unit with the formula $\mathrm{F}_{2} \mathrm{C}-\mathrm{CF}_{2}$. A sample of the polymer consists of fractions with the following distribution of chains:

| Fraction | Average no. <br> of repeat units | Amount (mol) <br> of polymer |
| :---: | :---: | :---: |
| 1 | 273 | 0.10 |
| 2 | 330 | 0.40 |
| 3 | 368 | 1.00 |
| 4 | 483 | 0.70 |
| 5 | 525 | 0.30 |
| 6 | 575 | 0.10 |

(a) Determine the molar mass of each fraction.
(b) Determine the number-average molar mass of the sample.
(c) Another type of average molar mass of a polymer sample is called the weight-average molar mass, $\mathcal{M}_{\mathrm{w}}$ :

$$
\mathcal{M}_{\mathrm{w}}=\frac{\Sigma(\mathcal{M} \text { of fraction } \times \text { mass of fraction })}{\text { total mass of all fractions }}
$$

Calculate the weight-average molar mass of the above sample.
12.127 A greenhouse contains $256 \mathrm{~m}^{3}$ of air at a temperature of $26^{\circ} \mathrm{C}$, and a humidifier in it vaporizes 4.20 L of water. (a) What is the pressure of water vapor in the greenhouse, assuming that none escapes and that the air was originally completely dry ( $d$ of $\mathrm{H}_{2} \mathrm{O}=1.00 \mathrm{~g} / \mathrm{mL}$ )? (b) What total volume of liquid water would have to be vaporized to saturate the air (i.e., achieve $100 \%$ relative humidity)? (See Table 5.4, p. 221.)
12.128 Like most transition metals, tantalum (Ta) exhibits several oxidation states. Give the formula of each tantalum compound whoseuntrènifarieted below:

12.129 Iron crystallizes in a body-centered cubic structure. The volume of one Fe atom is $8.38 \times 10^{-24} \mathrm{~cm}^{3}$, and the density of Fe is $7.874 \mathrm{~g} / \mathrm{cm}^{3}$. Find an approximate value for Avogadro's number.
12.130 Corn is a valuable source of industrial chemicals. For example, furfural is prepared from corncobs. It is an important solvent in synthetic rubber manufacturing, and it is reduced to furfuryl alcohol, which is used to make polymer resins. Furfural can also be oxidized to 2 -furoic acid.

furfuryl alcohol

furfural

2-furoic acid
(a) Which of these compounds can form H bonds? Draw structures in each case.
(b) The molecules of some substances can form an "internal" H bond, that is, an H bond within a molecule. This takes the form
of a polygon with atoms as corners and bonds as sides and an H bond as one of the sides. Which of these molecules is (are) likely to form a stable internal H bond? Draw the structure. (Hint: Structures with 5 or 6 atoms as corners are most stable.)
12.131 On a humid day in New Orleans, the temperature is $22.0^{\circ} \mathrm{C}$, and the partial pressure of water vapor in the air is 31.0 torr. The 9000 -ton air-conditioning system in the Louisiana Superdome maintains an inside air temperature of $22.0^{\circ} \mathrm{C}$ also, but a partial pressure of water vapor of 10.0 torr. The volume of air in the dome is $2.4 \times 10^{6} \mathrm{~m}^{3}$, and the total pressure inside and outside the dome are both 1.0 atm . (a) What mass of water (in metric tons) must be removed every time the inside air is completely replaced with outside air? (Hint: How many moles of gas are in the dome? How many moles of water vapor? How many moles of dry air? How many moles of outside air must be added to the air in the dome to simulate the composition of outside air?)
(b) Find the heat released when this mass of water condenses.
12.132 The boiling point of amphetamine, $\mathrm{C}_{9} \mathrm{H}_{13} \mathrm{~N}$, is $201^{\circ} \mathrm{C}$ at 760 torr and $83^{\circ} \mathrm{C}$ at 13 torr. What is the concentration (in $\mathrm{g} / \mathrm{m}^{3}$ ) of amphetamine when it is in contact with $20 .{ }^{\circ} \mathrm{C}$ air?
12.133 Diamond has a face-centered cubic unit cell, with four more C atoms in tetrahedral holes within the cell. Densities of diamonds vary from $3.01 \mathrm{~g} / \mathrm{cm}^{3}$ to $3.52 \mathrm{~g} / \mathrm{cm}^{3}$ because C atoms are missing from some holes. (a) Calculate the unit-cell edge length of the densest diamond. (b) Assuming the cell dimensions are fixed, how many C atoms are in the unit cell of the diamond with the lowest density?
12.134 Is it possible for a salt of formula $\mathrm{AB}_{3}$ to have a facecentered cubic unit cell of anions with cations in all the eight available holes? Explain.
12.135 The density of solid gallium at its melting point is $5.9 \mathrm{~g} / \mathrm{cm}^{3}$, whereas that of liquid gallium is $6.1 \mathrm{~g} / \mathrm{cm}^{3}$. Is the temperature at the triple point higher or lower than the normal melting point? Is the slope of the solid-liquid line for gallium positive or negative?
12.136 A 4.7-L sealed bottle containing 0.33 g of liquid ethanol, $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}$, is placed in a refrigerator and reaches equilibrium with its vapor at $-11^{\circ} \mathrm{C}$. (a) What mass of ethanol is present in the vapor? (b) When the container is removed and warmed to room temperature, $20 .{ }^{\circ} \mathrm{C}$, will all the ethanol vaporize? (c) How much liquid ethanol would be present at $0.0^{\circ} \mathrm{C}$ ? The vapor pressure of ethanol is 10 . torr at $-2.3^{\circ} \mathrm{C}$ and 40 . torr at $19^{\circ} \mathrm{C}$.
12.137 Substance A has the following properties.

| mp at $1 \mathrm{~atm}:$ | $-20 .{ }^{\circ} \mathrm{C}$ | bp at $1 \mathrm{~atm}:$ | $85^{\circ} \mathrm{C}$ |
| :--- | :---: | :--- | :---: |
| $\Delta H_{\text {fus }}:$ | $180 . \mathrm{J} / \mathrm{g}$ | $\Delta H_{\text {vap }}:$ | $500 . \mathrm{J} / \mathrm{g}$ |
| $c_{\text {solid }}:$ | $1.0 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$ | $c_{\text {liquid }}:$ | $2.5 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$ |
| $c_{\text {gas }}:$ | $0.5 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$ |  |  |

At 1 atm , a $25-\mathrm{g}$ sample of A is heated from $-40 .{ }^{\circ} \mathrm{C}$ to $100 .{ }^{\circ} \mathrm{C}$ at a constant rate of $450 \mathrm{~J} / \mathrm{min}$. (a) How many minutes does it take to heat the sample to its melting point? (b) How many minutes does it take to melt the sample? (c) Perform any other necessary calculations, and draw a curve of temperature vs. time for the entire heating process.
12.138 An aerospace manufacturer is building a prototype experimental aircraft that cannot be detected by radar. Boron nitride is chosen for incorporation into the body parts, and the boric acid/ammonia method is used to prepare the ceramic material. Given $85.5 \%$ and $86.8 \%$ yields for the two reaction steps, how much boron nitride can be prepared from 1.00 metric ton of boric acid and $12.5 \mathrm{~m}^{3}$ of ammonia at 275 K and $3.07 \times 10^{3} \mathrm{kPa}$ ?

Assume that ammonia does not behave ideally under these conditions and is recycled completely in the reaction process.
12.139 The ball-and-stick models below represent three compounds with the same molecular formula, $\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}_{2}$ :

(a) Which compound(s) can form intermolecular H bonds?
(b) Which has the highest viscosity?
12.140 The $\Delta H_{\mathrm{f}}^{\circ}$ of gaseous dimethyl ether $\left(\mathrm{CH}_{3} \mathrm{OCH}_{3}\right)$ is $-185.4 \mathrm{~kJ} / \mathrm{mol}$; the vapor pressure is 1.00 atm at $-23.7^{\circ} \mathrm{C}$ and 0.526 atm at $-37.8^{\circ} \mathrm{C}$. (a) Calculate $\Delta H_{\text {vap }}^{\circ}$ of dimethyl ether. (b) Calculate $\Delta H_{\mathrm{f}}^{\circ}$ of liquid dimethyl ether.
12.141 The crystal structure of sodium is based on the bodycentered cubic unit cell. What is the mass of one unit cell of Na ? 12.142 KF has the same type of crystal structure as NaCl . The unit cell of KF has an edge length of 5.39 Å. Find the density of KF. 12.143 The intrinsic viscosity of a solute in a solvent, $[\eta]_{\text {solvent }}$, is the portion of the total viscosity due to the solute and is related to solute shape. In polymer science, it relates as well to intermolecular interactions between solvent and polymer: higher $[\eta]_{\text {solvent }}$ means stronger interaction. The $[\eta]_{\text {solvent }}$ values of polymers in solution are given by the Mark-Houwink equation, $[\eta]_{\text {solvent }}=K \mathcal{M}^{a}$, where $\mathcal{M}$ is the molar mass of the polymer, and $K$ and $a$ are constants specific to the polymer and solvent. Use the data below for $25^{\circ} \mathrm{C}$ to answer the following questions:

| FrPdymenceI | Solvent | $K(\mathrm{~mL} / \mathrm{g})$ | $a$ |
| :---: | :--- | :---: | :---: |
| Polystyrene | Benzene | $9.5 \times 10^{-3}$ | 0.74 |
|  | Cyclohexane | $8.1 \times 10^{-2}$ | 0.50 |
| Polyisobutylene | Benzene | $8.3 \times 10^{-2}$ | 0.50 |
|  | Cyclohexane | $2.6 \times 10^{-1}$ | 0.70 |

(a) A polystyrene sample has a molar mass of $104,160 \mathrm{~g} / \mathrm{mol}$. Calculate the intrinsic viscosity in benzene and in cyclohexane. Which solvent has stronger interactions with the polymer?
(b) A different polystyrene sample has a molar mass of $52,000 \mathrm{~g} / \mathrm{mol}$. Calculate its $[\eta]_{\text {benzene. }}$. Given a polymer standard of known $\mathcal{M}$, how could you use its measured $[\eta$ ] in a given solvent to determine the molar mass of any sample of that polymer? (c) Compare $[\eta]$ of a polyisobutylene sample [repeat unit $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CCH}_{2}$ ] with a molar mass of $104,160 \mathrm{~g} / \mathrm{mol}$ with that of the polystyrene in part (a). What does this suggest about the solvent-polymer interactions of the two samples?
12.144 At a local convenience store, you purchase a cup of coffee, but, at $98.4^{\circ} \mathrm{C}$, it is too hot to drink. You add 23.0 g of ice that is $-2.2^{\circ} \mathrm{C}$ to 248 mL of the coffee. What is the final temperature of the coffee? (Assume the heat capacity and density of the coffee are the same as water and the coffee cup is well insulated.)
12.145 One way of purifying gaseous $\mathrm{H}_{2}$ is to pass it under high pressure through the holes of a metal's crystal structure. Palladium, which adopts a cubic closest packed structure, absorbs more $\mathrm{H}_{2}$ than any other element and is one of the metals currently used for this purpose. Although the metal-hydrogen interaction is unclear, it is estimated that the density of absorbed $\mathrm{H}_{2}$ approaches that of liquid hydrogen ( $70.8 \mathrm{~g} / \mathrm{L}$ ). What volume (in L) of gaseous $\mathrm{H}_{2}$, measured at STP, can be packed into the spaces of $1 \mathrm{dm}^{3}$ of palladium metal?

## 13

Starting the Day with a Mixture Cream mixing into a cup of coffee demonstrates just how familiar mixtures are in everyday life. In this chapter, you'll see why mixtures form and how we quantify their composition and make use of their remarkable physical behavior.

## The Properties of Mixtures: Solutions and Colloids

13.1 Types of Solutions: Intermolecular Forces and Solubility
Intermolecular Forces in Solution Liquid Solutions Gas Solutions and Solid Solutions
13.2 Intermolecular Forces and Biological Macromolecules
Structures of Proteins Dual Polarity and Function Structure of DNA Structure of Cellulose

13.3 Why Substances Dissolve: Understanding the Solution Process<br>Heats of Solution and Solution Cycles<br>Heats of Hydration<br>The Solution Process and the Change in Entropy<br>13.4 Solubility as an Equilibrium<br>Process<br>Effect of Temperature<br>Effect of Pressure

13.5 Quantitative Ways of Expressing Concentration
Molarity and Molality
Parts of Solute by Parts of Solution Interconverting Concentration Terms
13.6 Colligative Properties of Solutions Nonvolatile Nonelectrolyte Solutions Solute Molar Mass
Volatile Nonelectrolyte Solutions Strong Electrolyte Solutions
13.7 The Structure and Properties of Colloids

Nearly all the gases, liquids, and solids that make up our world are mixturestwo or more substances physically mixed together but not chemically combined. Synthetic mixtures, such as glass and soap, usually contain relatively few components, whereas natural mixtures, such as seawater and soil, are more complex, often containing more than 50 different substances. Living mixtures, such as trees and students, are the most complex-even a simple bacterial cell contains well over 5000 different compounds (Table 13.1).

Table 13.1 Approximate Composition of a Bacterium

*Includes precursors and metabolites.

Recall from Chapter 2 that a mixture has two defining characteristics: its composition is variable, and it retains some properties of its components. In this chapter, we focus on two common types of mixtures: solutions and colloids. A solution is a homogeneous mixture, one with no boundaries separating its components; thus, a solution exists as one phase. A heterogeneous mixture has two or more phases. The pebbles in concrete or the bubbles in champagne are visible indications that these are heterogeneous mixtures. A colloid is a heterogeneous mixture in which one component is dispersed as very fine particles in another component, so distinct phases are not easy to see. Smoke and milk are colloids. The essential difference between a solution and a colloid is one of particle size:

- In a solution, the particles are individual atoms, ions, or small molecules.
- In a colloid, the particles are typically either macromolecules or aggregations of small molecules that are not large enough to settle out.

As you'll see later in the chapter, these molecular-scale differences result in many observable differences.

IN THIS CHAPTER . . . We examine intermolecular forces between solute and solvent and their role in forming solutions. To predict solubility in different solvents, we focus on the dual polarity of simple organic compounds and then apply this idea to biological macromolecules and the cell membrane. We investigate why a substance dissolves in terms of the enthalpy of solution and the dispersal of matter that occurs during the solution process. To understand the second factor, the concept of entropy is introduced. We examine the equilibrium nature of solubility and see how temperature and pressure affect it. Various concentration units are discussed and interconverted. You'll see why the physical properties of solutions are different from those of pure substances and how we employ those differences. Then we investigate colloids and apply solution and colloid chemistry to the purification of water.

## Concepts \& Skills to Review before you study this chapter

- classification and separation of mixtures (Section 2.9)
- calculations involving mass percent (Section 3.1) and molarity (Section 3.5)
- electrolytes; water as a solvent (Sections 4.1 and 12.5)
- mole fraction and Dalton's law of partial pressures (Section 5.4)
- types of intermolecular forces and the concept of polarizability (Section 12.3)
- distinction between monomer and polymer (Section 12.7)
- vapor pressure of liquids (Section 12.2)

Dispersion
(0.05-40)

Figure 13.1 The major types of intermolecular forces in solutions. Forces are listed in decreasing order of strength (with values in $\mathrm{kJ} / \mathrm{mol}$ ), and an example of each is shown with space-filling models.

### 13.1 TYPES OF SOLUTIONS: INTERMOLECULAR FORCES AND SOLUBILITY

We often describe solutions in terms of one substance dissolving in another: the solute dissolves in the solvent. Usually, the solvent is the most abundant component of a given solution. In some cases, however, the substances are miscible, that is, soluble in each other in any proportion; in such cases, it may not be meaningful to call one the solute and the other the solvent.

The solubility ( $\boldsymbol{S}$ ) of a solute is the maximum amount that dissolves in a fixed quantity of a particular solvent at a specified temperature, given that excess solute is present. Different solutes have different solubilities. For example, for sodium chloride $(\mathrm{NaCl}), S=39.12 \mathrm{~g} / 100 . \mathrm{mL}$ water at $100 .{ }^{\circ} \mathrm{C}$, whereas for silver chloride $(\mathrm{AgCl}), S=0.0021 \mathrm{~g} / 100 . \mathrm{mL}$ water at $100 .{ }^{\circ} \mathrm{C}$. Obviously, NaCl is much more soluble in water than AgCl is. (Solubility is also expressed in other units, as you'll see later.) Although solubility has a quantitative meaning, dilute and concentrated are qualitative terms that refer to the relative amounts of solute: a dilute solution contains much less dissolved solute than a concentrated one.

From everyday experience, you know that some solvents can dissolve a given solute, whereas others can't. For example, butter doesn't dissolve in water, but it does in cooking oil. A major factor determining whether a solution forms is the relative strength of the intermolecular forces within and between solute and solvent. Experience shows that substances with similar types of intermolecular forces dissolve in each other. This fact is summarized in the rule-of-thumb like dissolves like. From a knowledge of these forces, we can often predict which solutes will dissolve in which solvents.

## Intermotegulap Forcesinsotutioner

All the intermolecular forces we discussed in Section 12.3 for pure substances also occur between solute and solvent in solutions (Figure 13.1):

1. Ion-dipole forces are the principal force involved in the solubility of ionic compounds in water. When a salt dissolves, each ion on the crystal's surface attracts the oppositely charged end of the water dipole. These attractive forces overcome those between the ions and break down the crystal structure. As each ion becomes separated, more water molecules cluster around it in hydration shells (Figure 13.2). Recent evidence shows that water's normal H bonding is altered only among molecules in the closest hydration shell. These molecules are H bonded to others slightly farther away, which are in turn H bonded to still other solvent water molecules. It's important to remember that this process does not lead to a jumble of ions and water molecules; rather, there is less freedom of motion for molecules in the closest hydration shell. For monatomic ions, the number of water molecules in the closest shell depends on the ion's size. Four water molecules can fit tetrahedrally around small ions, such as $\mathrm{Li}^{+}$, while larger ions, such as $\mathrm{Na}^{+}$and $\mathrm{F}^{-}$, have six water molecules surrounding them octahedrally.
2. Hydrogen bonding is especially important in aqueous solution. In fact, it is a primary factor in the solubility in water-and, thus, cell fluid-of many oxygen- and nitrogen-containing organic and biological compounds, such as alcohols, sugars, amines, and amino acids. (Recall that O and N are small and electronegative, so their bound H atoms are partially positive and can get very close to the O of $\mathrm{H}_{2} \mathrm{O}$.)
3. Dipole-dipole forces, in the absence of H bonding, account for the solubility of polar organic molecules, such as acetaldehyde $\left(\mathrm{CH}_{3} \mathrm{CHO}\right)$, in polar, nonaqueous solvents like chloroform $\left(\mathrm{CHCl}_{3}\right)$.
4. Ion-induced dipole forces are one of two types of charge-induced dipole forces, which rely on the polarizability of the components. They result when an ion's charge distorts the electron cloud of a nearby nonpolar molecule. This type of force plays an essential biological role that initiates the binding of the $\mathrm{Fe}^{2+}$

Figure 13.2 Hydration shells around an aqueous ion. When an ionic compound dissolves in water, ion-dipole forces orient water molecules around the separated ions to form hydration shells. The cation shown here is octahedrally surrounded by six water molecules, which form H bonds with water molecules in the next hydration shell, and those form H bonds with others farther away.
ion in hemoglobin and an $\mathrm{O}_{2}$ molecule in the bloodstream. Because an ion increases the magnitude of any nearby dipole, ion-induced dipole forces also contribute to the solubility of salts in less polar solvents, such as LiCl in ethanol.
5. Dipole-induced dipole forces, also based on polarizability, are weaker than the ion-induced dipole forces because the magnitude of the charge is smaller (Coulomb's law). They arise when a polar molecule distorts the electron cloud of a nearby nonpolar molecule. The solubility in water, limited though it is, of atmospheric $\mathrm{O}_{2}, \mathrm{~N}_{2}$, and the noble gases is due in large part to these forces. Paint thinners and grease solvents also function through dipole-induced dipole forces.
6. Dispersion forces contribute7oche selubility of all squtestradh elwents, but they are the principal type of intermofecular force in solutions of nonpolar substances, such as petroleum and gasoline.

As you'll see in Section 13.2, these intermolecular forces are also responsible for keeping cellular macromolecules in their biologically active shapes.

## Liquid Solutions and the Role of Molecular Polarity

Solutions can be gaseous, liquid, or solid. In general, the physical state of the solvent determines the physical state of the solution. We focus on liquid solutions because they are by far the most common and important.

From cytoplasm to tree sap, gasoline to cleaning fluid, iced tea to urine, solutions in which the solvent is a liquid are familiar in everyday life. Water is the most prominent solvent because it is so common and dissolves so many ionic and polar substances. But there are many other liquid solvents, and their polarity ranges from very polar to nonpolar.
Liquid-Liquid and Solid-Liquid Solutions Many salts dissolve in water because the strong ion-dipole attractions that water molecules form with the ions are very similar to the strong attractions between the ions themselves and, therefore, can substitute for them. The same salts are insoluble in hexane $\left(\mathrm{C}_{6} \mathrm{H}_{14}\right)$ because the weak ion-induced dipole forces their ions could form with the nonpolar molecules of this solvent cannot substitute for attractions between the ions. Similarly, oil does not dissolve in water because the weak dipole-induced dipole forces between oil and water molecules cannot substitute for the strong H bonds between water molecules. Oil does dissolve in hexane, however, because the dispersion forces in one substitute readily for the dispersion forces in the other. Thus, for a solution to form, "like dissolves like" means that the forces created between solute and solvent must be comparable in strength to the forces destroyed within both the solute and the solvent.

To examine this idea further, let's compare the solubilities of a series of alcohols in two solvents that act through very different intermolecular forces-water and hexane. Alcohols are organic molecules with a hydroxyl ( -OH ) group bound to a hydrocarbon group. The simplest type of alcohol has the general formula $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{n} \mathrm{OH}$; we'll consider alcohols with $n=0$ to 5 . We can view an alcohol molecule as consisting of two portions: the polar -OH group and the nonpolar hydrocarbon chain. The - OH portion forms strong H bonds with water and weak dipole-induced dipole forces with hexane. The hydrocarbon portion interacts through dispersion forces with hexane and through dipole-induced dipole forces with water.

In Table 13.2, the models show the relative change in size of the polar and nonpolar portions of the alcohol molecules. In the smaller alcohols (one to three carbons), the hydroxyl group is a relatively large portion, so the molecules interact with each other through H bonding, just as water molecules do. When the smaller alcohols mix with water, H bonding within solute and within solvent is replaced by H bonding between solute and solvent (Figure 13.3). As a result, these smaller alcohols are miscible with water.

Water solubility decreases dramatically for alcohols larger than three carbons, and those with chains longer than six carbons are insoluble in water. For these larger alcohols to dissolve, the nonpolar chains have to move between the water molecules, substituting their weak attractions with those water molecules for strong H bonds among the water molecules themselves. The - OH portion of the alcohol does form H bonds to water, but these don't outweigh the H bonds among water molecules that break to make room for the hydrocarbon portion.

Table 13.2 shows that the opposite trend occurs with hexane. For alcohols in hexane, the major solute-solvent and solvent-solvent interactions are dispersion forces. The weak forces between the - OH group of methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ and Apago PDE Fnhancer

## Table 13.2 Solubility* of a Series of Alcohols in Water and Hexane

| Alcohol | Model | Solubility in Water | Solubility in Hexane |
| :---: | :---: | :---: | :---: |
| $\underset{\text { (methanol) }}{\mathrm{CH}_{3} \mathrm{OH}}$ |  | $\infty$ | 1.2 |
| $\underset{\text { (ethanol) }}{\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}}$ |  | $\infty$ | $\infty$ |
| $\begin{gathered} \mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{OH} \\ \text { (1-propanol) } \end{gathered}$ |  | $\infty$ | $\infty$ |
| $\underset{\text { (1-butanol) }}{\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{3} \mathrm{OH}}$ |  | 1.1 | $\infty$ |
| $\underset{\text { (1-pentanol) }}{\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{4} \mathrm{OH}}$ |  | 0.30 | $\infty$ |
| $\underset{\text { (1-hexanol) }}{\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{5} \mathrm{OH}}$ |  | 0.058 | $\infty$ |

*Expressed in mol alcohol/ 1000 g solvent at $20^{\circ} \mathrm{C}$.

Figure 13.3 Like dissolves like: solubility of methanol in water. The H bonds in water and in methanol are similar in type and strength, so they can substitute for one another. Thus, methanol is soluble in water; in fact, the two substances are miscible.
hexane cannot substitute for the strong H bonding among $\mathrm{CH}_{3} \mathrm{OH}$ molecules, so the solubility of methanol in hexane is relatively low. In any larger alcohol, however, dispersion forces become increasingly more important, and these can substitute for dispersion forces in pure hexane; thus, solubility increases. With no strong solvent-solvent forces to be replaced by weak solute-solvent forces, even the two-carbon chain of ethanol has strong enough solute-solvent attractions to be miscible in hexane.

Many other organic molecules have polar and nonpolar portions, and the predominance of one portion or the other determines their solubility in different solvents. For example, carboxylic acids and amines behave very much like alcohols. Thus, methanoic acid ( HCOOH , formic acid) and methanamine $\left(\mathrm{CH}_{3} \mathrm{NH}_{2}\right)$ are miscible with water and much lest satatyon hexmed whereahbexaneacid $\left[\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{4} \mathrm{COOH}\right]$ and 1-hexanamine $\left[\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{5} \mathrm{NH}_{2}\right.$ are slightly soluble in water and very soluble in hexane.

## SAMPLE PROBLEM 13.1 Predicting Relative Solubilities of Substances

PROBLEM Predict which solvent will dissolve more of the given solute:
(a) Sodium chloride in methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ or in 1-propanol $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}\right)$
(b) Ethylene glycol $\left(\mathrm{HOCH}_{2} \mathrm{CH}_{2} \mathrm{OH}\right)$ in hexane $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\right)$ or in water
(c) Diethyl ether $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OCH}_{2} \mathrm{CH}_{3}\right)$ in water or in ethanol $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\right)$

PLAN We examine the formulas of the solute and each solvent to determine the types of forces that could occur. A solute tends to be more soluble in a solvent whose intermolecular forces are similar to, and therefore can substitute for, its own.
SOLUTION (a) Methanol. NaCl is an ionic solid that dissolves through ion-dipole forces. Both methanol and 1-propanol contain a polar - OH group, but 1-propanol's longer hydrocarbon chain can form only weak forces with the ions, so it is less effective at substituting for the ionic attractions in the solute.
(b) Water. Ethylene glycol molecules have two - OH groups, so the molecules interact with each other through H bonding. They are more soluble in $\mathrm{H}_{2} \mathrm{O}$, whose H bonds can substitute for their own H bonds better than the dispersion forces in hexane can.
(c) Ethanol. Diethyl ether molecules interact with each other through dipole-dipole and dispersion forces and can form H bonds to both $\mathrm{H}_{2} \mathrm{O}$ and ethanol. The ether is more soluble in ethanol because that solvent can form H bonds and substitute for the ether's dispersion forces. Water, on the other hand, can form H bonds with the ether, but it lacks any hydrocarbon portion, so it forms much weaker dispersion forces with that solute.
FOLLOW-UP PROBLEM 13.1 Which solute is more soluble in the given solvent?
(a) 1-Butanol $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}\right)$ or 1,4-butanediol $\left(\mathrm{HOCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}\right)$ in water
(b) Chloroform $\left(\mathrm{CHCl}_{3}\right)$ or carbon tetrachloride $\left(\mathrm{CCl}_{4}\right)$ in water
"Greener" Organic Solvents Volatile organic solvents have many uses in paints and other coatings, in cleaning agents, and in propellants for hairspray, cooking oils, lubricants, and so forth. But they also play a role in smog formation and may have adverse health effects. These concerns have led to the development of "greener" processes, such as the use of nonvolatile organic solvents, nonaqueous ionic liquid solvents, supercritical fluids, and solvent-free and water-based methods. With the implementation of these approaches, atmospheric emissions and worker exposure are greatly reduced.

| Table 13.3 | Correlation Between <br> Boiling Point and <br> Solubility in Water |  |
| :--- | :---: | ---: |
| Gas | Solubility (M)* | bp (K) |
| He | $4.2 \times 10^{-4}$ | 4.2 |
| Ne | $6.6 \times 10^{-4}$ | 27.1 |
| $\mathrm{~N}_{2}$ | $10.4 \times 10^{-4}$ | 77.4 |
| CO | $15.6 \times 10^{-4}$ | 81.6 |
| $\mathrm{O}_{2}$ | $21.8 \times 10^{-4}$ | 90.2 |
| NO | $32.7 \times 10^{-4}$ | 121.4 |

*At 273 K and 1 atm.

Gas-Liquid Solutions Gases that are nonpolar, such as $\mathrm{N}_{2}$, or are nearly so, such as NO, have low boiling points because their intermolecular attractions are weak. Likewise, they are not very soluble in water because solute-solvent forces are weak. In fact, as Table 13.3 shows, for nonpolar gases, boiling point generally correlates with solubility in water.

In some cases, the small amount of a nonpolar gas that does dissolve is essential to a process. The most important environmental example is the solubility of $\mathrm{O}_{2}$ in water. At $25^{\circ} \mathrm{C}$ and 1 atm , the solubility of $\mathrm{O}_{2}$ is only $3.2 \mathrm{~mL} / 100 \mathrm{~mL}$ of water, but aquatic animal life would die without this small amount. In other cases, the solubility of a gas may seem high because the gas is not only dissolving but also reacting with the solvent or another component. Oxygen seems much more soluble in blood than in water because $\mathrm{O}_{2}$ molecules are continually bonding with hemoglobin molecules in red blood cells. Similarly, carbon dioxide, which is essential for aquatic plants and coral-reef growth, seems very soluble in water $\left(\sim 81 \mathrm{~mL}\right.$ of $\mathrm{CO}_{2} / 100 . \mathrm{mL}$ of $\mathrm{H}_{2} \mathrm{O}$ at $25^{\circ} \mathrm{C}$ and 1 atm$)$ because it is reacting, in addition to simply dissolving:

$$
\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{HCO}_{3}^{-}(a q)
$$

## Gas Solutions and Solid Solutions

Despite the central place of liquid solutions in chemistry, gaseous solutions and solid solutions also have vital importance and numerous applications.
Gas-Gas Solutions All gases are infinitely soluble in one another. Air is the classic example of a gaseous solution, consisting of about 18 gases in widely differing proportions. Anesthetic gas proportions are finely adjusted to the needs of the patient and the length of the surgical procedure. The ratios of components in many industualgas mixtupes, suchasce/ $\mathrm{H}_{2}$ Gheyngas production or $\mathrm{N}_{2} / \mathrm{H}_{2}$ in ammonia production, are controlled to optimize product yield under varying conditions of temperature and pressure.

Gas-Solid Solutions When a gas dissolves in a solid, it occupies the spaces between the closely packed particles. Hydrogen gas can be purified by passing an impure sample through a solid metal such as palladium. Only the $\mathrm{H}_{2}$ molecules are small enough to enter the spaces between the Pd atoms, where they form $\mathrm{Pd}-\mathrm{H}$ covalent bonds. Under high $\mathrm{H}_{2}$ pressure, the H atoms are passed along the Pd crystal structure and emerge from the solid as $\mathrm{H}_{2}$ molecules.

The ability of gases to penetrate a solid also has disadvantages. The electrical conductivity of copper, for example, is drastically reduced by the presence of $\mathrm{O}_{2}$, which dissolves into the crystal structure and reacts to form copper(I) oxide. High-conductivity copper is prepared by melting and recasting the copper in an $\mathrm{O}_{2}$-free atmosphere.

Solid-Solid Solutions Because solids diffuse so little, their mixtures are usually heterogeneous; an example is gravel mixed with sand. Some solid-solid solutions can be formed by melting the solids and then mixing them and allowing them to freeze. Many alloys, mixtures of elements that have an overall metallic character, are examples of solid-solid solutions (although several common alloys have microscopic heterogeneous regions). In substitutional alloys, such as brass (Figure 13.4A) and sterling silver, atoms of another element substitute for some atoms of the main element in the structure. In interstitial alloys, atoms of another element (often a nonmetal) fill some of the spaces (interstices) between atoms of the main element. For example, some forms of carbon steel (Figure 13.4B) are interstitial alloys of iron with a small amount of carbon.

Waxes are another familiar type of solid-solid solution. Most waxes are amorphous solids that may contain small regions of crystalline regularity. A natural wax is a solid of biological origin that is insoluble in water but dissolves in

A Brass, a substitutional alloy
Figure 13.4 The arrangement of atoms in two types of alloys. A, Brass is a substitutional alloy in which zinc atoms substitute for copper atoms at many of copper's face-centered cubic packing sites.

B, Some forms of carbon steel are interstitial alloys in which carbon atoms lie in the holes (interstices) of the body-centered cubic crystal structure of iron.
nonpolar solvents. Many plants have waxy coatings on their leaves and fruit to prevent evaporation of interior water.

## Section Summary

Solutions are homogeneous mixtures consisting of a solute dissolved in a solvent through the action of intermolecular forces. - The solubility of a solute in a given amount of solvent is the maximum amount that can dissolve at a specified temperature. (For gaseous solutes, the pressure must be specified also.) • In addition to the intermolecular forces that exist in pure substances, ion-dipole, ion-induced dipole, and dipole-induced dipole forces occur in solution. If similar intermolecular forces
 ionic compounds dissolve in water, the ions become surrounded by hydration shells of H -bonded water molecules. - Solubility of organic molecules in various solvents depends on their polarity and the extent of their polar and nonpolar portions. - The solubility of nonpolar gases in water is low because of weak intermolecular forces. Gases are miscible with one another and dissolve in solids by fitting into spaces in the crystal structure. - Solid-solid solutions, such as alloys and waxes, form when the components are mixed while molten.

### 13.2 INTERMOLECULAR FORCES AND BIOLOGICAL MACROMOLECULES

The forces responsible for solutes dissolving in solvents also play a fundamental role in maintaining the complex three-dimensional shapes of cellular biopolymers: proteins, nucleic acids, and polysaccharides. The structures of these molecules, and that of the cell membrane itself, can be understood through two simple ideas involving intermolecular forces: (1) polar and ionic groups interact with the surrounding cellular water, while nonpolar groups do not, and (2) distant groups on a large molecule are often close enough to interact through intermolecular forces.

In this section, we'll see how these forces stabilize the three types of biological macromolecules and the cell membrane; in Chapter 15 , we'll see the reactions that form these molecules and how their structure is crucial to their function.

## The Structures of Proteins

Proteins are unbranched polymers formed from monomers called amino acids, organic compounds with amine $\left(-\mathrm{NH}_{2}\right)$ and carboxyl $(-\mathrm{COOH})$ groups in the same molecule. Proteins range from about 50 amino acids ( $\mathcal{\mu} \approx 5 \times 10^{3} \mathrm{~g} / \mathrm{mol}$ ) to several thousand $\left(\mathcal{M} \approx 5 \times 10^{5} \mathrm{~g} / \mathrm{mol}\right)$. Protein shapes are determined completely by the sequence of amino acids in the chain. Some proteins have few amino acids

Waxes for Home and Auto Beeswax, the remarkable structural material that bees secrete to build their combs, is a complex mixture of fatty acids, longchain carboxylic acids, and hydrocarbons in which some of the molecules contain chains more than 40 carbon atoms long. Carnauba wax, from a South American palm, is a mixture of compounds, each consisting of a fatty acid bound to a longchain alcohol. It is hard but forms a thick gel in nonpolar solvents, perfect for car waxes.

Figure 13.5 The physiological form of an amino acid. Under physiological conditions, amino acids have charged groups. There are about 20 different side chains.

Figure 13.6 A portion of a polypeptide chain. The peptide bond holds the monomers together in a protein. Three peptide bonds (orange screens) joining four amino acids occur in this portion of a polypeptide chain. Note the repeating pattern of the chain: peptide bond-$\alpha$-carbon-peptide bond- $\alpha$-carbonand so on. Also note that the side chains (gray screens) dangle off the main chain.
in repeating patterns and, thus, extended helical or sheetlike shapes. These function to give structure to hair, skin, and so forth. Others have many more types of amino acids and more complex, globular shapes. These function as antibodies that defend against infection, enzymes that speed metabolic reactions, membrane gates and pumps that control ion concentrations in the cell, and so forth. Let's see how the amino acid composition influences the shapes of globular proteins.
The Polarity of Amino-Acid Side Chains In the cell, an individual amino acid has four groups bonded to its $\alpha$-carbon (Figure 13.5): charged carboxyl $\left(-\mathrm{COO}^{-}\right)$and amine $\left(-\mathrm{NH}_{3}{ }^{+}\right)$groups, an H atom, and a side chain, which ranges from an H atom to a two-ringed $\mathrm{C}_{9} \mathrm{H}_{8} \mathrm{~N}$ group. The peptide bond is the covalent linkage between amino acids in a protein and is formed between the carboxyl group of one amino acid and the amine group of the next. (We discuss amino acid structures and details of peptide bond formation in Chapter 15.)

In essence, then, the backbone of a protein consists of an $\alpha$-carbon bonded to a peptide bond, which is bonded to the next $\alpha$-carbon bonded to the next peptide bond, and so forth, with the various side chains dangling off the $\alpha$-carbons on alternate sides of the chain (Figure 13.6). Globular proteins are made up of about 20 different types of amino acids, each characterized by its particular side chain (gray screens). The simple classification of amino acids we use here focuses on their polarity and/or charge: nonpolar, polar, and ionic. A few examples are

Intermolecular Forces and Protein Shape The forces responsible for protein shapes are the same bonding and intermolecular forces that operate for all molecules. A long protein chain has many bends, and distant groups of the same molecule end up near enough to interact.

Figure 13.7 depicts the forces operating in proteins dissolved in the aqueous cell medium. (Membrane-bound proteins have an important structural difference, as we'll see shortly.) The covalent peptide bonds create the chain. The - SH ends of two cysteine side chains often form an - $\mathrm{S}-\mathrm{S}-$ bond, a covalent disulfide bridge that brings together distant parts of the chain. Polar and ionic side chains usually protrude into the surrounding cell fluid, interacting with water through ion-dipole forces and H bonds. But sometimes oppositely charged ends of ionic side chains lie near each other, and the $-\mathrm{COO}^{-}$and $-\mathrm{NH}_{3}{ }^{+}$groups form an electrostatic salt link (or ion pair), which secures the chain's bends. Helical and sheetlike segments arise from $H$ bonds between the $C=O$ of one peptide bond and the $N-H$ of another. Other H bonds involving atoms in peptide bonds or in side chains act to keep distant portions of the chain near each other. Nonpolar side chains interact through dispersion forces within the nonaqueous protein interior. Thus, through the influence of intermolecular forces among the protein's side chains, soluble proteins have polar-ionic exteriors and nonpolar interiors.

A protein's shape is so important because, as we emphasize in Chapter 15, the amino acid sequence determines the protein's shape, and the shape determines its function.

Figure 13.7 The forces that maintain protein structure. A portion of a general protein shows that a combination of covalent, ionic, and intermolecular forces (both within the protein and between the protein and water) is responsible for the overall protein shape. (Water molecules and some amino-acid side chains are shown as ball-and-stick models within a space-filling contour.)

The Hardness and Softness of Soaps
The cation of a soap influences its properties greatly. Lithium soaps are hard and high melting and are used in car lubricants. Softer, more water-soluble sodium soaps are used as common bar soap. Potassium soaps are low melting and used as liquid soaps. The insolubility of calcium soaps explains why it is difficult to clean clothes in hard water, which typically contains $\mathrm{Ca}^{2+}$ ions (see Chemical Connections, p. 542).

## Dual Polarity and Function

The dual polarity that we discussed earlier with reference to solubility can help us understand the function of systems as diverse as soaps, antibiotics, and cell membranes.

Soaps and Detergents A soap is the salt of a strong base (metal hydroxide) and a fatty acid, a carboxylic acid with a long hydrocarbon chain. A typical soap molecule has an even number of carbon atoms and is usually made up of a nonpolar "tail" 15-19 carbons long and a polar-ionic "head" consisting of the - $\mathrm{COO}^{-}$ group and a cation. For example, sodium stearate, $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{16} \mathrm{COONa}$, is a major component of many bar soaps:

Sodium stearate $\mathrm{C}_{17} \mathrm{H}_{35} \mathrm{COONa}$
When grease on your hands or clothes is immersed in soapy water, the nonpolar tails of the soap molecules interact with the nonpolar grease molecules through dispersion forces, while the polar-ionic heads interact with the water through iondipole forces and H bonds. Agitation creates tiny aggregates of grease molecules with embedded soap molecules, whose polar-ionic heads stick into the water. These aggregates are flushed away by added water (Figure 13.8). Detergents have a similar structure of nonpolar tail and polar-ionic head, but they typically consist of an $-\mathrm{SO}_{3}{ }^{-}$group (and an inorganic cation) attached to a long hydrocarbon group.

## Apago PDF Enhancer

Figure 13.8 The structure and function of a soap. The tails of soap molecules interact with nonpolar molecules in grease through dispersion forces, while the heads interact with water through H bonds and ion-dipole forces. Agitation breaks up the grease stain into small soap-grease aggregates that rinsing flushes away.

The Lipid Bilayer The most abundant molecules in the cell membranes of most species are phospholipids. They consist of two long fatty acid chains and a charged organophosphate group all linked to glycerol, a three-carbon trialcohol. Thus, as Figure 13.9 shows, phospholipids, like soaps, have a polar-ionic head and a nonpolar tail.

In water, phospholipids undergo a remarkable self-assembly into an extended sheetlike double layer of molecules, called a lipid bilayer. On each surface of the bilayer, the charged heads face the water, and within the interior of the bilayer, the nonpolar tails face each other. So that the tails at the ends of the bilayer are not exposed to the aqueous surroundings, the bilayer tends to close on itself. In the laboratory, bilayers can be made to form spherical vesicles that trap water inside. The result is an energetically favorable structure that optimizes the various intermolecular forces: ion-dipole forces between polar heads and water inside and out, dispersion forces between nonpolar tails within the bilayer, and minimum contact between nonpolar tails and water. Experiments show that the lipid bilayer is impermeable to ions and most polar molecules, including water.
Structure of the Cell Membrane The cell membrane is a perfect example of the effect of intermolecular forces in a complex biological assembly. A typical animal cell membrane is about 8 nm thick and consists of the phospholipid bilayer embedded with various proteins that may comprise as much as $50 \%$ by mass of the membrane. Depending on the type of cell, membrane proteins function as pumps that actively move ions and specific molecules in or out, channels or gates that passively allow ions or molecules in or out, or receptors for small biomolecules (see Chemical Connections, pp. 402-403), or they may be involved in energy production or metabolic reactions.

The structures of membrane proteins differ in a fundamental way from those of the soluble proteins we discussedprevoas 8 Insolube protasin most cases, polar groups are found on the exterior and nonpolar groups on the interior, away from water. Studies of many systems, from red blood cells to photosynthetic bacteria, show that membrane proteins have this arrangement partly inverted: the exterior of the protein region that lies within the lipid bilayer consists of nonpolar amino-acid side chains. Dispersion forces between these groups and the hydrocarbon tails of the membrane lipids stabilize this orientation (Figure 13.10).

Figure 13.9 Membrane phospholipids.
The phospholipids found in cell membranes all have similar portions, with a polar-ionic head and a nonpolar tail; lecithin (phosphatidylcholine) is shown here. The purple-and-gray shape is a simplified representation of the structure.

Figure 13.10 Intermolecular forces and membrane structure.

Figure 13.11 The mode of action of an antibiotic. Gramicidin $A$ is a tubelike molecule, nonpolar on the outside and polar on the inside. After dissolving into the nonpolar interior of a bacterial cell membrane via dispersion forces, pairs of gramicidin molecules aligned end to end span the membrane's thickness. Ions diffuse through the polar interior of these molecules, which destroys the cell's ion balance and its segregation of $\mathrm{Na}^{+}$outside and $\mathrm{K}^{+}$inside.

Action of Antibiotics A clear example of how this orientation of molecules in the cell membrane functions is seen in channel-forming antibiotics. Antibiotics are produced byponemicroorganism te destroy another, and many have been adapted by medical science to fight bacterial infection.

One function of the membrane is to balance internal and external ion concentrations: $\mathrm{Na}^{+}$is excluded from the cell, and $\mathrm{K}^{+}$is kept inside. If this ionic segregation is disrupted, the organism dies. Gramicidin A and similar antibiotics disrupt the ion balance by forming a channel in the bacterial membrane through which ions can flow (Figure 13.11). Two helical gramicidin A molecules-with nonpolar groups outside and polar groups inside-lie end to end and span the bacterial membrane. The nonpolar outside helps the molecule dissolve into the membrane of the target bacterium through dispersion forces, and the polar groups on the inside pass the ions along through ion-dipole forces, like a "bucket brigade." Indeed, over $10^{7}$ ions per second pass through a single channel! Through this polar passageway ions diffuse in and out, and the organism dies.

## The Structure of DNA

The chemical information that guides the design, construction, and function of all proteins is contained in nucleic acids, unbranched polymers that consist of monomers called mononucleotides. Each mononucleotide consists of an N-containing base, a sugar, and a phosphate group (Figure 13.12). In DNA (deoxyribonucleic acid), the sugar is 2-deoxyribose, in which -H substitutes for -OH on the second C atom of the five-carbon sugar ribose.

The repeating pattern of the backbone of a DNA chain is sugar linked to phosphate linked to sugar linked to phosphate, and so on. Attached to each sugar is one of four nitrogen-containing bases. The bases are flat ring structures that dangle off the sugar-phosphate chain, similar to the way amino-acid side chains dangle off the protein chain.

Figure 13.13 The double helix of DNA. In this space-filling segment of DNA (left), the polar, negatively charged, sugar-phosphate portion (pink) lies on the exterior of the structure and interacts with the aqueous cell fluid through ion-dipole forces and H bonds. Dispersion forces
stabilize the stacked, nonpolar bases (gray) in the interior. The ball-andstick model (right) shows that specific pairs are attached by H bonds: a guanine-cytosine pair is shown.

Intermolecular Forces and the Double Helix In the cell nucleus, DNA exists as two chains wrapped around each other in a double helix (Figure 13.13). Intermolecular forces play a central role in stabilizing this structure. On the exterior, negatively charged sugar-phosphate chains form ion-dipole and H bonds with the aqueous surroundings. In the interior, the flat, nitrogen-containing bases stack above each other, which allows extensizediteraction wroughtigeesionferges. Most important, specific pairs of bases form interchain $H$ bonds; that is, each base in one chain is always H bonded with the same partner base in the other chain. Thus, the base sequence of one chain is the $H$-bonded complement of the base sequence of the other.

A DNA molecule contains millions of H bonds linking bases in these prescribed pairs. The total energy of the H bonds keeps the chains together, but each H bond is weak enough (around $5 \%$ of a typical covalent single bond) that a few at a time can break as the chains separate during crucial cellular processes. Linear segments of DNA act as genes, chemical blueprints for synthesizing the organism's proteins. In Chapter 15, we'll see how base pairing through H bonding is essential to protein synthesis (the process by which the cell makes its proteins) and DNA replication (the process by which the genes copy themselves during cell division).

## The Structure of Cellulose

Strength and energy storage are the two main functions of polysaccharides, polymers consisting of monomers called monosaccharides, or simple sugars. The three major natural polysaccharides-cellulose, starch, and glycogen-consist entirely of glucose units, but they differ in the way the units are linked and in the extent of crosslinking. In aqueous systems, glucose occurs as a six-membered ring with five - OH groups attached (Figure 13.14).

The same intermolecular forces operate in all three of these polysaccharides, but we'll focus here on cellulose, the most abundant organic chemical on Earth. Cellulose is the only unbranched polysaccharide of the three and consists entirely of long chains of glucose monomers. Picture parallel chains of linked glucose

Figure 13.14 The cyclic structure of glucose in aqueous solution.

Figure 13.15 The structure of cellu-
lose. The polysaccharide cellulose exists as chains of glucose molecules. Hydrogen bonds within each chain, between chains to form layers, and between layers give cellulose great strength.

units lying next to each other in three dimensions, their - OH groups everywhere (Figure 13.15). The opportunities for dispersion forces and extensive interchain H bonding are enormous. In fact, the great strength of wood is due largely to the countless H bonds among cellulose chains. (We compare the structures of the three polysaccharides in Chapter 15.)

## Section Summary

 Neh henamIntermolecular forces stabilize the structures of biological macromolecules-proteins, nucleic acids, and polysaccharides-and the cell membrane. - In soluble proteins, polar and ionic amino-acid side chains face the water, while nonpolar side chains interact with each other in the molecular interior. - Soaps have a polar-ionic head and a nonpolar tail that allow them to dissolve grease while interacting with water. • Membranes consist of phospholipids that also have two polarities. They assemble in a selfsealing, water-impermeable lipid bilayer. In a cell membrane, the lipid bilayer has embedded proteins whose nonpolar side chains face the surrounding bilayer. Channelforming antibiotics also have nonpolar exteriors and polar interiors. - DNA forms a double helix with a sugar-phosphate, polar-ionic exterior. In the interior, bases H bond in specific pairs and stack through dispersion forces. - Cellulose consists of long chains of linked glucose molecules, which interact through extensive H bonding.

### 13.3 WHY SUBSTANCES DISSOLVE: UNDERSTANDING THE SOLUTION PROCESS

As a qualitative predictive tool, "like dissolves like" is helpful in many cases. As you might expect, this handy macroscopic rule is based on the molecular interactions that occur between solute and solvent particles. To see why like dissolves like, let's break down the solution process conceptually into steps and examine them in terms of changes in enthalpy and entropy of the system. We discussed enthalpy in Chapter 6 and focus on it first here. The concept of entropy is introduced at the end of this section and treated quantitatively in Chapter 20.

## Heats of Solution and Solution Cycles

Picture a general solute and solvent about to form a solution. Both consist of particles attracting each other. For one substance to dissolve in another, three events must occur: (1) solute particles must separate from each other, (2) some solvent

particles must separate to make room for the solute particles, and (3) solute and solvent particles must mix together. No matter what the nature of the attractions within the solute and within the solvent, some energy must be absorbed for particles to separate, and some energy is released when they mix and attract each other. As a result of these changes, the solution process is typically accompanied by a change in enthalpy. We can divide the process into these three steps, each with its own enthalpy term:
Step 1. Solute particles separate from each other. This step involves overcoming intermolecular attractions, so it is endothermic:

Step 2. Solvent particles separate from each other. This step also involves overcoming attractions, so it is endothermic, too:

$$
\text { Solvent (aggregated) }+ \text { heat } \longrightarrow \text { solvent }(\text { separated }) \quad \Delta H_{\text {solvent }}>0
$$

Step 3. Solute and solvent particles mix. The particles attract each other, so this step is exothermic:

Solute (separated) + solvent (separated) $\longrightarrow$ solution + heat $\Delta H_{\text {mix }}<0$
The total enthalpy change that occurs when a solution forms from solute and solvent is the heat of solution ( $\Delta \boldsymbol{H}_{\text {soln }}$ ), and we combine the three individual enthalpy changes to find it. The overall process is called a thermochemical solution cycle and is yet another application of Hess's law:

$$
\begin{equation*}
\Delta H_{\text {soln }}=\Delta H_{\text {solute }}+\Delta H_{\text {solvent }}+\Delta H_{\text {mix }} \tag{13.1}
\end{equation*}
$$

(In Section 9.2 we conceptually broke down the heat of formation of an ionic compound into component enthalpies in a similar way using a Born-Haber cycle.) If the sum of the endothermic terms $\left(\Delta H_{\text {solute }}+\Delta H_{\text {solvent }}\right)$ is smaller than the exothermic term $\left(\Delta H_{\text {mix }}\right), \Delta H_{\text {soln }}$ is negative; that is, the process is exothermic. Figure 13.16 A is an enthalpy diagram for the formation of such a solution. If the sum of the endothermic terms is larger than the exothermic term, $\Delta H_{\text {soln }}$ is positive; that is, the process is endothermic (Figure 13.16B). However, if $\Delta H_{\text {soln }}$ is highly positive, the solute may not dissolve to any significant extent in that solvent.

## Heats of Hydration: Ionic Solids in Water

We can simplify the solution cycle for aqueous systems. The $\Delta H_{\text {solvent }}$ and $\Delta H_{\text {mix }}$ components of the heat of solution are difficult to measure individually. Combined, these terms represent the enthalpy change during solvation, the process of surrounding a solute particle with solvent particles. Solvation in water is called hydration. Thus, enthalpy changes for separating the water molecules $\left(\Delta H_{\text {solvent }}\right)$

Figure 13.16 Solution cycles and the enthalpy components of the heat of solution. $\Delta H_{\text {soln }}$ can be thought of as the sum of three enthalpy changes: $\Delta H_{\text {solvent }}$ (separating the solvent; always $>0$ ), $\Delta H_{\text {solute }}$ (separating the solute; always $>0$ ), and $\Delta H_{\text {mix }}$ (mixing solute and solvent; always $<0$ ). $\mathbf{A}, \Delta H_{\text {mix }}$ is larger than the sum of $\Delta H_{\text {solute }}$ and $\Delta H_{\text {solvent }}$, so $\Delta H_{\text {soln }}$ is negative (exothermic process). $\mathbf{B}, \Delta H_{\text {mix }}$ is smaller than the sum of the others, so $\Delta H_{\text {soln }}$ is positive (endothermic process).

| Table 13.4 | Trends in Ionic Heats <br> of Hydration <br> lonic |  |
| :--- | :---: | :---: |
| lon | Radius <br> (pm) | $\Delta H_{\text {hydr }}$ <br> $(\mathrm{kJ} / \mathrm{mol})$ |
| Group 1A(1) |  |  |

| $\mathrm{Mg}^{2+}$ | 72 | -1903 |
| $\mathrm{Ca}^{2+}$ | 100 | -1591 |
| $\mathrm{Sr}^{2+}$ | 118 | -1424 |
| $\mathrm{Ba}^{2+}$ | 135 | -1317 |
| $\mathrm{Group} \mathrm{7A(17)}^{2+}$ |  |  |
| $\mathrm{F}^{-}$ | 133 | -431 |
| $\mathrm{Cl}^{-}$ | 181 | -313 |
| $\mathrm{Br}^{-}$ | 196 | -284 |
| $\mathrm{I}^{-}$ | 220 | -247 |

A $\mathrm{NaCl} . \Delta H_{\text {lattice }}$ is slightly larger than $\Delta H_{\text {hydr }}$ : $\Delta H_{\text {soln }}$ is small and positive.

and mixing the solute with them $\left(\Delta H_{\text {mix }}\right)$ are combined into the heat of hydration $\left(\boldsymbol{\Delta} \boldsymbol{H}_{\text {hydr }}\right)$. In water, Equation 13.1 becomes

$$
\Delta H_{\text {soln }}=\Delta H_{\text {solute }}+\Delta H_{\text {hydr }}
$$

The heat of hydration is a key factor in dissolving an ionic solid. Breaking H bonds in water is more than compensated for by forming strong ion-dipole forces, so hydration of an ion is always exothermic. The $\Delta H_{\mathrm{hydr}}$ of an ion is defined as the enthalpy change for the hydration of 1 mol of separated (gaseous) ions:
$\mathrm{M}^{+}(g)\left[\right.$ or $\left.\mathrm{X}^{-}(g)\right] \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{M}^{+}(a q)\left[\right.$ or $\left.\mathrm{X}^{-}(a q)\right] \quad \Delta H_{\text {hydr of the ion }}$ (always $<0$ )
Heats of hydration exhibit trends based on the charge density of the ion, the ratio of the ion's charge to its volume. In general, the higher the charge density is, the more negative $\Delta H_{\text {hydr }}$ is. According to Coulomb's law, the greater the ion's charge is and the closer the ion can approach the oppositely charged end of the water molecule's dipole, the stronger the attraction. Therefore,

- A $2+$ ion attracts $\mathrm{H}_{2} \mathrm{O}$ molecules more strongly than a $1+$ ion of similar size. - A small $1+$ ion attracts $\mathrm{H}_{2} \mathrm{O}$ molecules more strongly than a large $1+$ ion.

Down a group of ions, for example, from $\mathrm{Na}^{+}$to $\mathrm{Cs}^{+}$in Group $1 \mathrm{~A}(1)$, the charge stays the same and the size increases; thus, the charge densities decrease, as do the heats of hydration. Going across the periodic table from Group 1A(1) to Group $2 \mathrm{~A}(2)$, the 2 A ion has a smaller radius and a greater charge, so its charge density and $\Delta H_{\text {hydr }}$ are greater. Table 13.4 shows these relationships for some ions.

The energy required to separate an ionic solute ( $\left.\Delta H_{\text {solute }}\right)$ into gaseous ions is its lattice energy ( $\Delta H_{\text {lattice }}$ ), and $\Delta H_{\text {solute }}$ is highly positive:

$$
\mathrm{M}^{+} \mathrm{X}^{-}(s) \longrightarrow \mathrm{M}^{+}(g)+\mathrm{X}^{-}(g) \quad \Delta H_{\text {solute }}(\text { always }>0)=\Delta H_{\text {lattice }}
$$

Thus, the heat of solution for ionic compounds in water combines the lattice energy (always positive) and the combined heats of hydration of cation and anion (alvaysngeativeDEF Fnhancer

$$
\begin{equation*}
\Delta H_{\text {soln }}=\Delta H_{\text {lattice }}+\Delta H_{\text {hydr of the ions }} \tag{13.2}
\end{equation*}
$$

The sizes of the individual terms determine the sign of the heat of solution.
Figure 13.17 shows enthalpy diagrams for dissolving three ionic solutes in water. The first, NaCl , has a small positive heat of solution $\left(\Delta H_{\text {soln }}=3.9 \mathrm{~kJ} / \mathrm{mol}\right)$.

Figure 13.17 Dissolving ionic compounds in water. The enthalpy diagram for an ionic compound in water includes $\Delta H_{\text {lattice }}$ ( $\Delta H_{\text {solute }}$; always positive) and the combined ionic heats of hydration ( $\Delta H_{\text {hydr }}$; always negative).

C $\mathrm{NH}_{4} \mathrm{NO}_{3} . \Delta H_{\text {lattice }}$ dominates: $\Delta H_{\text {soln }}$ is large and positive.

Its lattice energy is only slightly greater than the combined ionic heats of hydration, so if you dissolve NaCl in water in a flask, you do not notice any temperature change. However, if you dissolve NaOH in water, the flask feels hot. The lattice energy for NaOH is much smaller than the combined ionic heats of hydration, so dissolving NaOH is highly exothermic ( $\Delta H_{\text {soln }}=-44.5 \mathrm{~kJ} / \mathrm{mol}$ ). Finally, if you dissolve $\mathrm{NH}_{4} \mathrm{NO}_{3}$ in water, the flask feels cold. In this case, the lattice energy is much larger than the combined ionic heats of hydration, so the process is quite endothermic $\left(\Delta H_{\text {soln }}=25.7 \mathrm{~kJ} / \mathrm{mol}\right)$.

## The Solution Process and the Change in Entropy

The heat of solution $\left(\Delta H_{\text {soln }}\right)$ is one of two factors that determine whether a solute dissolves in a solvent. The other factor concerns the natural tendency of a system to spread out, distribute, or disperse, its energy in as many ways as possible. A thermodynamic variable called entropy ( $S$ ) is directly related to the number of ways that a system can distribute its energy, which in turn is closely related to the freedom of motion of the particles and the number of ways they can be arranged.

Let's see what it means for a system to "disperse its energy." We'll first compare the three physical states and then compare solute and solvent with solution. In a solid, the particles are relatively fixed in their positions, but in the liquid, they are free to move around each other. This greater freedom of motion means the particles can distribute their kinetic energy in more ways; thus, the liquid has higher entropy than the solid ( $S_{\text {liquid }}>S_{\text {solid }}$ ). The gas, in turn, has higher entropy than the liquid because the particles have much more freedom of motion ( $S_{\mathrm{gas}}>$ $S_{\text {liquid }}$ ). Another way to state this is that the change in entropy when the liquid vaporizes to a gas ( $\Delta S_{\text {vap }}$ ) is positive; that is, $\Delta S_{\text {vap }}>0$.

Similarly, a solution usually has higher entropy than the pure solute and pure solvent. Here, the number of waystodistyute the entrgyandlthe freedom motion of the particles is related to the different molecules becoming interspersed and, thus, to the number of different interactions between the molecules. There are far more interactions possible when solute and solvent are mixed than when they are pure; thus, $S_{\text {soln }}>\left(S_{\text {solute }}+S_{\text {solvent }}\right)$, or $\Delta S_{\text {soln }}>0$.

From everyday experience, we know that solutions form naturally, whereas pure solutes and solvents do not. We'll see in Chapter 20 that energy must be expended to reverse this tendency of systems to distribute their energy in more ways-to get "mixed up." Water treatment facilities, oil refineries, metal foundries, and many other industrial processes expend enormous quantities of energy in order to reverse this natural tendency and separate mixtures into pure components.

The solution process involves the interplay of two factors-the change in enthalpy and the change in entropy. Systems tend toward a state of lower enthalpy and higher entropy. In many cases, the relative magnitudes of $\Delta H_{\text {soln }}$ and $\Delta S_{\text {soln }}$ determine whether a solution forms.

To see this interplay of enthalpy and entropy, let's consider three solutesolvent pairs in which different influences dominate. In our first example, sodium chloride does not dissolve in hexane $\left(\mathrm{C}_{6} \mathrm{H}_{14}\right)$, as you would predict from the dissimilar intermolecular forces. As Figure 13.18A on page 518 shows, separating the solvent is easy because the dispersion forces are relatively weak, but separating the ionic solute requires supplying $\Delta H_{\text {lattice }}$. Mixing releases very little heat because the ion-induced dipole attractions between $\mathrm{Na}^{+}$( or $\mathrm{Cl}^{-}$) ions and hexane molecules are weak. The sum of the endothermic terms is much larger than the exothermic term, so $\Delta H_{\text {soln }}$ is highly positive. In this case, a solution does not form because the entropy increase that would accompany the mixing of solute and solvent is much smaller than the enthalpy increase required to separate the ions.

Hot Packs, Cold Packs, and SelfHeating Soup Strain a muscle or sprain a joint and you may obtain temporary relief by applying the appropriate heat of solution. Hot packs and cold packs consist of a thick outer pouch containing water and a thin inner pouch containing a salt. A squeeze on the outer pouch breaks the inner pouch, and the salt dissolves. Most hot packs use anhydrous $\mathrm{CaCl}_{2}\left(\Delta H_{\text {soln }}=\right.$ $-82.8 \mathrm{~kJ} / \mathrm{mol}$ ), whereas cold packs use $\mathrm{NH}_{4} \mathrm{NO}_{3}\left(\Delta H_{\text {soln }}=25.7 \mathrm{~kJ} / \mathrm{mol}\right)$. The change in temperature can be large-a cold pack, for instance, can bring the solution from room temperature down to $0^{\circ} \mathrm{C}$-but a pack's usable time is limited to around half an hour. In Japan, some cans of soup have double walls, with an ionic compound in a packet and water between the walls. When you open the can, the packet breaks, and the exothermic solution process, which can quickly reach about $90^{\circ} \mathrm{C}$, warms the soup.

Figure 13.18 Enthalpy diagrams for dissolving NaCl and octane in hexane.
A, Because attractions between $\mathrm{Na}^{+}$(or $\mathrm{Cl}^{-}$) ions and hexane molecules are weak, $\Delta H_{\text {mix }}$ is much smaller than $\Delta H_{\text {solute }}$. Thus, $\Delta H_{\text {soln }}$ is so positive that NaCl does not dissolve in hexane. B, Intermolecular forces in octane and in hexane are so similar that $\Delta H_{\text {soln }}$ is very small. Octane dissolves in hexane because the solution has greater entropy than the pure components.

The second solute-solvent pair is octane $\left(\mathrm{C}_{8} \mathrm{H}_{18}\right)$ and hexane. Both consist of nonpolar molecules held together by dispersion forces of comparable strength. We therefore predict that octane is soluble in hexane; in fact, they are infinitely soluble (miscible). But this does not necessarily mean that a great deal of heat is released; in fact, $\Delta H_{\text {soln }}$ is around zero (Figure 13.18B). With no enthalpy change driving the process, octane dissolves in hexane because the entropy increases greatly when the pure substances mix. Thus, the large increase in entropy drives formation of this solution.

In some cases, a large enough increase in entropy can cause a solution to form even when the enthalpy increases significantly $\left(\Delta H_{\text {soln }}>0\right)$. As Figure 13.17 C showed, when ammonium nitrate $\left(\mathrm{NH}_{4} \mathrm{NO}_{3}\right)$ dissolves in water, the process is very endothermic. Nevertheless, in that case, the increase in entropy that occurs when the crystal breaks down and the ions mix with water molecules more than compensates for the increase in enthalpy. The enthalpy/entropy interplay in physical and chemical systems is covered in depth in Chapter 20.

## Section Summary

An overall heat of solution can be obtained from a thermochemical solution cycle as the sum of two endothermic steps (solute separation and solvent separation) and one exothermic step (solute-solvent mixing). - In aqueous solutions, the combination of solvent separation and mixing is called hydration. Ionic heats of hydration are always negative because of strong ion-dipole forces. - Most systems have a natural tendency to increase their entropy (disperse their energy in more ways), and a solution has greater entropy than the pure solute and solvent. - The combination of enthalpy and entropy changes determines whether a solution forms. A substance with a positive $\Delta H_{\text {soln }}$ dissolves only if the entropy increase is large enough to outweigh it.

### 13.4 SOLUBILITY AS AN EQUILIBRIUM PROCESS

When an ionic solid dissolves, ions leave the solid and become dispersed in the solvent. Some dissolved ions collide occasionally with the undissolved solute and recrystallize. As long as the rate of dissolving is greater than the rate of recrystallizing, the concentration of ions rises. Eventually, given enough solid, ions are dissolving at the same rate as ions in the solution are recrystallizing (Figure 13.19).

Figure 13.19 Equilibrium in a saturated solution. In a saturated solution, equilibrium exists between excess solid solute and dissolved solute. At a particular temperature, the number of solute particles dissolving (white arrows) per unit time equals the number recrystallizing (black arrows).

At this point, even though dissolving and recrystallizing continue, there is no further change in the concentration with time. The system has reached equilibrium; that is, excess undissolved solute is in equilibrium with the dissolved solute:

$$
\text { Solute }(\text { undissolved }) \rightleftharpoons \text { solute }(\text { dissolved })
$$

This solution is called saturated: it contains the maximum amount of dissolved solute at a given temperature in the presence of undissolved solute. Filter off
 solve. A solution that contains less than this concentration of dissolved solute is called unsaturated: add more solute, and more will dissolve until the solution becomes saturated.

In some cases, we can prepare a solution that contains more than the equilibrium concentration of dissolved solute. Such a solution is called supersaturated. It is unstable relative to the saturated solution: if you add a "seed" crystal of solute, or just tap the container, the excess solute crystallizes immediately, leaving a saturated solution (Figure 13.20). You can often prepare a supersaturated solution of a solute if it has greater solubility at a higher temperature. While warming the contents of the flask, you dissolve more than the amount of solute required to prepare a saturated solution at some lower temperature and then slowly cool the solution. If the excess solute remains dissolved, the solution is supersaturated.

A Saturated Solution Is Like a Pure Liquid and Its Vapor Equilibrium processes in a saturated solution are analogous to those for a pure liquid and its vapor in a closed flask (Section 12.2). For the liquid, rates of vaporizing and condensing are equal; in the solution, rates of dissolving and recrystallizing are equal. In the liquid-vapor system, particles leave the liquid to enter the vapor, and their concentration (pressure) increases until, at equilibrium, the available space above the liquid is "saturated" with vapor at a given temperature. In the solution, solute particles leave the crystal to enter the solvent, and their concentration increases until, at equilibrium, the available solvent is saturated with solute at a given temperature.

Figure 13.20 Sodium acetate crystallizing from a supersaturated solution. When a seed crystal of sodium acetate is added to a supersaturated solution of the compound (A), solute begins to crystallize out of solution (B) and continues to do so until the remaining solution is saturated (C).

## Effect of Temperature on Solubility

Temperature affects the solubility of most substances. You may have noticed, for example, that not only does sugar dissolve more quickly in hot tea than in iced tea, but more sugar dissolves; in other words, the solubility of sugar in tea is greater at higher temperatures. Let's examine the effects of temperature on the solubility of solids and of gases.

Temperature and the Solubility of Solids Like sugar, most solids are more soluble at higher temperatures. Figure 13.21 shows the solubility of several ionic compounds in water as a function of temperature. Note that most of the graphed lines rise from left to right. Cerium sulfate is the only exception shown in the figure, but several other salts, mostly sulfates, behave similarly. Some salts exhibit increasing solubility up to a certain temperature and then decreasing solubility at still higher temperatures.

We might think that the sign of $\Delta H_{\text {soln }}$ would indicate the effect of temperature. Most ionic solids have a positive $\Delta H_{\text {soln }}$ because their lattice energies are greater than their heats of hydration. Thus, heat is absorbed to form the solution from solute and solvent, and if we think of heat as a reactant, a rise in temperature should increase the rate of the forward process:

$$
\text { Solute }+ \text { solvent }+ \text { heat } \rightleftharpoons \text { saturated solution }
$$

Tabulated $\Delta H_{\text {soln }}$ values refer to the enthalpy change for a solution to reach the standard state of $1 M$, but in order to understand the effect of temperature, we need to know the sign of the enthalpy change very close to the point of saturation, which may not be the same. To use earlier examples, tabulated values give a negative $\Delta H_{\text {soln }}$ for NaOH and a positive one for $\mathrm{NH}_{4} \mathrm{NO}_{3}$, yet both compounds are more soluble at higher temperatures. The point is that solubility is a complex bentvï,ghe, althouth the effectofemperature ultimately reflects the equilibrium nature of solubility, no single measure can help us predict the effect for a given solute.

Figure 13.21 The relation between solubility and temperature for several ionic compounds. Most ionic compounds have higher solubilities at higher temperatures. Cerium sulfate is one of several exceptions.

Temperature and Gas Solubility in Water The effect of temperature on gas solubility is much more predictable. When a solid dissolves in a liquid, the solute particles must separate, so energy must be added; thus, for a solid, $\Delta H_{\text {solute }}>0$. In contrast, gas particles are already separated, so $\Delta H_{\text {solute }} \approx 0$. Because the hydration step is exothermic ( $\Delta H_{\mathrm{hydr}}<0$ ), the sum of these two terms must be negative. Thus, for all gases in water, $\Delta H_{\text {soln }}<0$ :

$$
\text { Solute }(g)+\operatorname{water}(l) \rightleftharpoons \text { saturated solution }(a q)+\text { heat }
$$

This equation means that gas solubility in water decreases with rising temperature. Gases have weak intermolecular forces, so there are relatively weak intermolecular forces between a gas and water. When the temperature rises, the average kinetic energy of the particles in solution increases, allowing the gas particles to easily overcome these weak forces and re-enter the gas phase.

This behavior can lead to an environmental problem known as thermal pollution. During many industrial processes, large amounts of water are taken from a nearby river or lake, pumped through the system to cool liquids, gases, and equipment, and then returned to the body of water at a higher temperature. The metabolic rates of fish and other aquatic animals increase in the warmer water released near the plant outlet; thus, their need for $\mathrm{O}_{2}$ increases, but the concentration of dissolved $\mathrm{O}_{2}$ is lower at the higher temperature. This oxygen depletion can harm these aquatic populations. Moreover, the warmer water is less dense, so it floats on the cooler water below and prevents $\mathrm{O}_{2}$ from reaching it. Thus, creatures living at lower levels become oxygen deprived as well. Farther from the plant, the water temperature returns to ambient levels and the $\mathrm{O}_{2}$ solubility increases. One way to lessen the problem is with cooling towers, which lower the temperature of the water before it exits the plant (Figure 13.22).

## Effect of Pressure on Solubitityago PDF Enhancer

Because liquids and solids are almost incompressible, pressure has little effect on their solubility, but it has a major effect on gas solubility. Consider the pistoncylinder assembly in Figure 13.23, with a gas above a saturated aqueous solution of the gas. At a given pressure, the same number of gas molecules enter and leave the solution per unit time; that is, the system is at equilibrium:

$$
\text { Gas }+ \text { solvent } \rightleftharpoons \text { saturated solution }
$$

If you push down on the piston, the gas volume decreases, its pressure increases, and gas particles collide with the liquid surface more often. Thus, more gas particles enter than leave the solution per unit time. Higher gas pressure disturbs the

Figure $\mathbf{1 3 . 2 2}$ Fighting thermal pollu-
tion. Steam billowing from cooling towers is common at large electric power plants. Hot water resulting from the cooling of gases and equipment enters near the top of the tower and cools in contact with air. The cooler water is then released back into the water source.

Figure 13.23 The effect of pressure on gas solubility. $A, A$ saturated solution of a gas is in equilibrium at pressure $P_{1}$. B, If the pressure is increased to $P_{2}$, the volume of the gas decreases. There-
fore, the frequency of collisions with the surface increases. C, As a result, more gas is in solution when equilibrium is re-established.

Scuba Diving and Soda Pop Although $\mathrm{N}_{2}$ is barely soluble in water or blood at sea level, high external pressures significantly increase its solubility. Scuba divers who breathe compressed air and dive below about 50 ft have much more $\mathrm{N}_{2}$ dissolved in their blood. If they ascend quickly to lower pressures, they may be afflicted with decompression sickness (the "bends"), as the dissolved $\mathrm{N}_{2}$ bubbles out of their blood and causes painful, sometimes fatal, blockage of capillaries. This condition can be avoided by using less soluble gases, such as He , in the breathing mixtures. In principle, the same thing happens when you open a can of a carbonated drink. In the closed can, dissolved $\mathrm{CO}_{2}$ is at equilibrium with 4 atm of $\mathrm{CO}_{2}$ gas in the space above it. In the open can, the dissolved $\mathrm{CO}_{2}$ is under 1 atm of air $\left(P_{\mathrm{CO}_{2}}=3 \times 10^{-4} \mathrm{~atm}\right)$, so $\mathrm{CO}_{2}$ bubbles out of solution. With time, the system reaches equilibrium with the $P_{\mathrm{CO}_{2}}$ in air: the drink goes "flat."
balance at equilibrium, so more gas dissolves to reduce this disturbance (a shift to the right in the preceding equation) until the system re-establishes equilibrium.

Henry's law expresses the quantitative relationship between gas pressure and solubility: the solubility of a gas $\left(S_{\mathrm{gas}}\right)$ is directly proportional to the partial pressure of the gas $\left(P_{\mathrm{gas}}\right)$ above the solution:

$$
\begin{equation*}
S_{\mathrm{gas}}=k_{\mathrm{H}} \times P_{\mathrm{gas}} \tag{13.3}
\end{equation*}
$$

where $k_{\mathrm{H}}$ is the Henry's law constant and is specific for a given gas-solvent combination at a given temperature. With $S_{\text {gas }}$ in $\mathrm{mol} / \mathrm{L}$ and $P_{\text {gas }}$ in atm, the units of $k_{\mathrm{H}}$ are $\mathrm{mol} / \mathrm{L} \cdot \mathrm{atm}$.

## SAMPLE PROBLEM 13.2 Using Henry's Law to Calculate Gas Solubility

PROBLEM The partial pressure of carbon dioxide gas inside a bottle of cola is 4 atm at $25^{\circ} \mathrm{C}$. What is the solubility of $\mathrm{CO}_{2}$ ? The Henry's law constant for $\mathrm{CO}_{2}$ dissolved in water is $3.3 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$ at $25^{\circ} \mathrm{C}$.
PLAN We know $P_{\mathrm{CO}_{2}}(4 \mathrm{~atm})$ and the value of $k_{\mathrm{H}}\left(3.3 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}\right)$, so we substitute them into Equation 13.3 to find $S_{\mathrm{CO}_{2}}$.
SOLUTION $S_{\mathrm{CO}_{2}}=k_{\mathrm{H}} \times P_{\mathrm{CO}_{2}}=\left(3.3 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}\right)(4 \mathrm{~atm})=0.1 \mathrm{~mol} / \mathrm{L}$
CHECK The units are correct for solubility. We rounded the answer to one significant figure because there is only one in the pressure value.
FOLLOW-UP PROBLEM 13.2 If air contains $78 \% \mathrm{~N}_{2}$ by volume, what is the solubility of $\mathrm{N}_{2}$ in water at $25^{\circ} \mathrm{C}$ and $1 \mathrm{~atm}\left(k_{\mathrm{H}}\right.$ for $\mathrm{N}_{2}$ in $\mathrm{H}_{2} \mathrm{O}$ at $\left.25^{\circ} \mathrm{C}=7 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}\right)$ ?

## Section Summary

A solution that contains the maximum amount of dissolved solute in the presence of excess undissolved solute is saturated. A state of equilibrium exists when a saturated solution in contact with excess solute, because solute particles are entering and leaving the solution at the same rate. - Most solids are more soluble at higher temperatures. - All gases have a negative $\Delta H_{\text {soln }}$ in water, so heating lowers gas solubility in water. - Henry's law says that the solubility of a gas is directly proportional to its partial pressure above the solution.

### 13.5 QUANTITATIVE WAYS OF EXPRESSING CONCENTRATION

Concentration is the proportion of a substance in a mixture, so it is an intensive property, one that does not depend on the quantity of mixture present: 1.0 L of $0.1 M \mathrm{NaCl}$ has the same concentration as 1.0 mL of $0.1 M \mathrm{NaCl}$. Concentration is most often expressed as the ratio of the quantity of solute to the quantity of solution, but sometimes it is the ratio of solute to solvent. Because both parts of the ratio can be given in units of mass, volume, or amount (mol), chemists employ several concentration terms, including molarity, molality, and various expressions of "parts of solute per part of solution" (Table 13.5).

## Molarity and Molality

Molarity $(M)$ is the number of moles of solute dissolved in 1 L of solution:

$$
\begin{equation*}
\text { Molarity }(M)=\frac{\text { amount }(\mathrm{mol}) \text { of solute }}{\text { volume }(\mathrm{L}) \text { of solution }} \tag{13.4}
\end{equation*}
$$

In Chapter 3, you used molarity to convert liters of solution into moles of dissolved solute. Expressing concentration in terms of molarity may have drawbacks, however. Because volume is affected by temperature, so is molarity. A solution expands when heated, so a unit volume of hot solution contains slightly less solute than a unit volume of cold solution. This can be a source of error in very precise

## Table 13.5 Concentration Definitions

| Concentration Term | Ratio |
| :---: | :---: |
| Molarity ( $M$ ) | amount (mol) of solute |
|  | volume (L) of solution |
| Molality ( $m$ ) | amount (mol) of solute |
|  | mass (kg) of solvent |
| Parts by mass | mass of solute |
|  | mass of solution |
| Parts by volume | volume of solute |
|  | volume of solution |
| Mole fraction ( $X$ ) | amount (mol) of solute |
|  | ) of solute + amount (mol) |

work. More importantly, because of solute-solvent interactions that are difficult to predict, solution volumes may not be additive; that is, adding $500 . \mathrm{mL}$ of one solution to 500 mL of another may not give $1000 . \mathrm{mL}$. Therefore, in precise work, a solution with a desired molarity may not be easy to prepare.

A concentration term that does not contain volume in its ratio is molality ( $\boldsymbol{m}$ ), the number of moles of solute dissolved in $1000 \mathrm{~g}(1 \mathrm{~kg})$ of solvent:

$$
\begin{equation*}
\text { Molality }(m)=\frac{\text { amount }(\mathrm{mol}) \text { of solute }}{\text { mass }(\mathrm{kg}) \text { of solvent }} \tag{13.5}
\end{equation*}
$$

Note that molality includes the quantity of solvent, not solution. And, most important, molal solutions are prepared byeasuing mases sofutandsarent not solvent or solution volume. Mass does not change with temperature, so neither does molality. Moreover, unlike volumes, masses are additive: adding 500. g of one solution to 500. g of another does give 1000. g of final solution. For these reasons, molality is a preferred unit when temperature, and hence density, may change, as in the examination of solutions' physical properties. For the special case of water, 1 L has a mass of 1 kg , so molality and molarity are nearly the same for dilute aqueous solutions.

## SAMPLE PROBLEM 13.3 Calculating Molality

PROBLEM What is the molality of a solution prepared by dissolving 32.0 g of $\mathrm{CaCl}_{2}$ in 271 g of water?
PLAN To use Equation 13.5, we convert mass of $\mathrm{CaCl}_{2}(32.0 \mathrm{~g})$ to amount (mol) with the molar mass $(\mathrm{g} / \mathrm{mol})$ and then divide by the mass of water $(271 \mathrm{~g})$, being sure to convert from grams to kilograms.
SOLUTION Converting from grams of solute to moles:

$$
\text { Moles of } \mathrm{CaCl}_{2}=32.0 \mathrm{~g} \mathrm{CaCl}_{2} \times \frac{1 \mathrm{~mol} \mathrm{CaCl}_{2}}{110.98 \mathrm{~g} \mathrm{CaCl}_{2}}=0.288 \mathrm{~mol} \mathrm{CaCl}_{2}
$$

Finding molality:

$$
\text { Molality }=\frac{\text { mol solute }}{\mathrm{kg} \text { solvent }}=\frac{0.288 \mathrm{~mol} \mathrm{CaCl}_{2}}{271 \mathrm{~g} \times \frac{1 \mathrm{~kg}}{10^{3} \mathrm{~g}}}=1.06 \mathrm{~m} \mathrm{CaCl} 2
$$

CHECK The answer seems reasonable: the given numbers of moles of $\mathrm{CaCl}_{2}$ and kilograms of $\mathrm{H}_{2} \mathrm{O}$ are about the same, so their ratio is about 1 .
FOLLOW-UP PROBLEM 13.3 How many grams of glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$ must be dissolved in 563 g of ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ to prepare a $2.40 \times 10^{-2} \mathrm{~m}$ solution?

Unhealthy Ultralow Concentrations Environmental toxicologists often measure extremely low concentrations of pollutants. The Centers for Disease Control and Prevention considers TCDD (tetrachlorodibenzodioxin, above) one of the most toxic substances known. It is a member of the dioxin family of chlorinated hydrocarbons, a byproduct of bleaching paper. TCDD is considered unsafe at soil levels above 1 ppb . From contact with air, water, and soil, most North Americans have an average of 0.01 ppb TCDD in their fatty tissues. The Environmental Protection Agency has assessed TCDD as unsafe at all levels measured.

## Parts of Solute by Parts of Solution

Several concentration terms are based on the number of solute (or solvent) parts present in a specific number of solution parts. The solution parts can be expressed in terms of mass, volume, or amount (mol).
Parts by Mass The most common of the parts-by-mass terms is mass percent, which you encountered in Chapter 3. The word percent means "per hundred," so mass percent of solute means the mass of solute dissolved in every 100. parts by mass of solution, or the mass fraction times 100:

$$
\begin{align*}
\text { Mass percent } & =\frac{\text { mass of solute }}{\text { mass of solute }+ \text { mass of solvent }} \times 100 \\
& =\frac{\text { mass of solute }}{\text { mass of solution }} \times 100 \tag{13.6}
\end{align*}
$$

Sometimes mass percent is symbolized as $\%(\mathbf{w} / \mathbf{w})$, indicating that the percentage is a ratio of weights (more accurately, masses). You may have seen mass percent values on jars of solid chemicals to indicate the amounts of impurities present. Two very similar terms are parts per million ( ppm ) by mass and parts per billion ( ppb ) by mass: grams of solute per million or per billion grams of solution. For these quantities, in Equation 13.6 , you multiply by $10^{6}$ or by $10^{9}$, respectively, instead of by 100 .
Parts by Volume The most common of the parts-by-volume terms is volume percent, the volume of solute in 100. volumes of solution:

$$
\begin{equation*}
\text { Volume percent }=\frac{\text { volume of solute }}{\text { volume of solution }} \times 100 \tag{13.7}
\end{equation*}
$$

 for example, is an aqueous solution of isopropyl alcohol (a three-carbon alcohol) that contains 70 volumes of isopropyl alcohol per 100 . volumes of solution, and the label indicates this as " $70 \%$ (v/v)." Parts-by-volume concentrations are most often used for liquids and gases. Minor atmospheric components occur in parts per million by volume (ppmv). For example, there are about 0.05 ppmv of the toxic gas carbon monoxide (CO) in clean air, 1000 times as much (about 50 ppmv of CO ) in air over urban traffic, and 10,000 times as much (about 500 ppmv of CO ) in cigarette smoke. Some extremely tiny concentrations of active substances are found in nature. Pheromones are organic compounds secreted by one member of a species to signal other members about food, danger, sexual readiness, and so forth. Many organisms, including dogs and monkeys, release pheromones, and researchers suspect that humans do as well. Some insect pheromones are active even at a few hundred molecules per milliliter of air, about 100 parts per quadrillion by volume (Figure 13.24).

A measure of concentration frequently used for aqueous solutions is \% (w/v), a ratio of solute weight (actually mass) to solution volume. Thus, a $1.5 \%$ (w/v)

Figure 13.24 The sex attractant of the gypsy moth. The pheromone secreted by the female gypsy moth (called disparlure) can attract a male over 0.5 mi away. Chemists synthesize pheromones for insect pest control.

NaCl solution contains 1.5 g of NaCl per 100. mL of solution. This way of expressing concentrations is particularly common in medical labs and other health-related facilities.

Mole Fraction The mole fraction $(\boldsymbol{X})$ of a solute is the ratio of number of solute moles to the total number of moles (solute plus solvent), that is, parts by mole. The mole percent is the mole fraction expressed as a percentage:

$$
\begin{equation*}
\text { Mole fraction }(X)=\frac{\text { amount }(\mathrm{mol}) \text { of solute }}{\text { amount }(\mathrm{mol}) \text { of solute }+ \text { amount }(\mathrm{mol}) \text { of solvent }} \tag{13.8}
\end{equation*}
$$

Mole percent $(\mathrm{mol} \%)=$ mole fraction $\times 100$
We discussed these terms in Chapter 5 in relation to Dalton's law of partial pressures for mixtures of gases, but they apply to liquids and solids as well. Concentrations given as mole fractions provide the clearest picture of the actual proportion of solute (or solvent) particles among all the particles in the solution.

## SAMPLE PROBLEM 13.4 Expressing Concentrations in Parts by Mass, Parts by Volume, and Mole Fraction

PROBLEM (a) Find the concentration of calcium (in ppm) in a $3.50-\mathrm{g}$ pill that contains 40.5 mg of Ca .
(b) The label on a $0.750-\mathrm{L}$ bottle of Italian chianti indicates " $11.5 \%$ alcohol by volume." How many liters of alcohol does the wine contain?
(c) A sample of rubbing alcohol contains 142 g of isopropyl alcohol $\left(\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}\right)$ and 58.0 g of water. What are the mole fractions of alcohol and water?
PLAN (a) We are given the masses of $\mathrm{Ca}(40.5 \mathrm{mg})$ and the pill $(3.50 \mathrm{~g})$. We convert the mass of Ca from mg to g , find the ratio of mass of Ca to mass of pill, and multiply by $10^{6}$ to obtain ppm. (b) We know the volume $\%(11.5 \%$, or 11.5 parts by volume of alcohol to 100 parts of chianti) and the total volume $(0.750 \mathrm{~mL})$, so we use Equation 13.7 to find the volume of alcohol. (c) We know the mass and formula of each component, so we convert masses to amounts (mol) and apply Equation 13.8 to find the mole fractions.
SOLUTION (a) Finding parts per million by mass of Ca. Combining the steps, we have

$$
\mathrm{ppm} \mathrm{Ca}=\frac{\text { mass of } \mathrm{Ca}}{\text { mass of pill }} \times 10^{6}=\frac{40.5 \mathrm{mg} \mathrm{Ca} \times \frac{1 \mathrm{~g}}{10^{3} \mathrm{mg}}}{3.50 \mathrm{~g}} \times 10^{6}=1.16 \times 10^{4} \mathrm{ppm} \mathrm{Ca}
$$

(b) Finding volume (L) of alcohol:

$$
\text { Volume }(\mathrm{L}) \text { of alcohol }=0.750 \mathrm{~L} \text { chianti } \times \frac{11.5 \mathrm{~L} \text { alcohol }}{100 . \mathrm{L} \text { chianti }}=0.0862 \mathrm{~L}
$$

(c) Finding mole fractions. Converting from grams to moles:

$$
\begin{aligned}
\text { Moles of } \mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH} & =142 \mathrm{~g} \mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH} \times \frac{1 \mathrm{~mol} \mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}}{60.09 \mathrm{~g} \mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}}=2.36 \mathrm{~mol} \mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH} \\
\text { Moles of } \mathrm{H}_{2} \mathrm{O} & =58.0 \mathrm{~g} \mathrm{H}_{2} \mathrm{O} \times \frac{1 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}}{18.02 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}}=3.22 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

Calculating mole fractions:

$$
\begin{aligned}
X_{\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}} & =\frac{\text { moles of } \mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}}{\text { total moles }}=\frac{2.36 \mathrm{~mol}}{2.36 \mathrm{~mol}+3.22 \mathrm{~mol}}=0.423 \\
X_{\mathrm{H}_{2} \mathrm{O}} & =\frac{\text { moles of } \mathrm{H}_{2} \mathrm{O}}{\text { total moles }}=\frac{3.22 \mathrm{~mol}}{2.36 \mathrm{~mol}+3.22 \mathrm{~mol}}=0.577
\end{aligned}
$$

CHECK (a) The mass ratio is about $0.04 \mathrm{~g} / 4 \mathrm{~g}=10^{-2}$, and $10^{-2} \times 10^{6}=10^{4} \mathrm{ppm}$, so it seems correct. (b) The volume $\%$ is a bit more than $10 \%$, so the volume of alcohol should be a bit more than $75 \mathrm{~mL}(0.075 \mathrm{~L})$. (c) Always check that the mole fractions add up to 1 : $0.423+0.577=1.000$.
FOLLOW-UP PROBLEM 13.4 An alcohol solution contains 35.0 g of 1-propanol $\left(\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}\right)$ and 150.g of ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$. Calculate the mass percent and the mole fraction of each alcohol.

## Interconverting Concentration Terms

All the terms we just discussed represent different ways of expressing concentration, so they are interconvertible. Keep these points in mind:

- To convert a term based on amount (mol) to one based on mass, you need the molar mass. These conversions are similar to the mass-mole conversions you've done earlier.
- To convert a term based on mass to one based on volume, you need the solution density. Given the mass of a solution, the density (mass/volume) gives you the volume, or vice versa.
- Molality involves quantity of solvent, whereas the other concentration terms involve quantity of solution.

## SAMPLE PROBLEM 13.5 Converting Concentration Terms

PROBLEM Hydrogen peroxide is a powerful oxidizing agent used in concentrated solution in rocket fuels and in dilute solution as a hair bleach. An aqueous solution of $\mathrm{H}_{2} \mathrm{O}_{2}$ is $30.0 \%$ by mass and has a density of $1.11 \mathrm{~g} / \mathrm{mL}$. Calculate its:
(a) Molality
(b) Mole fraction of $\mathrm{H}_{2} \mathrm{O}_{2}$
(c) Molarity

PLAN We know the mass \% (30.0) and the density ( $1.11 \mathrm{~g} / \mathrm{mL}$ ). (a) For molality, we need the amount (mol) of solute and the mass (kg) of solvent. Assuming 100.0 g of $\mathrm{H}_{2} \mathrm{O}_{2}$ solution allows us to express the mass \% directly as grams of substance. We subtract the grams of $\mathrm{H}_{2} \mathrm{O}_{2}$ to obtain the grams of solvent. To find molality, we convert grams of $\mathrm{H}_{2} \mathrm{O}_{2}$ to moles and divide by mass of solvent (converting g to kg ). (b) To find the mole fraction, we use the number of moles of $\mathrm{H}_{2} \mathrm{O}_{2}$ [from part (a)] and convert the grams of $\mathrm{H}_{2} \mathrm{O}$ to moles. Then we divide the moles of $\mathrm{H}_{2} \mathrm{O}_{2}$ by the total moles. (c) To find molarity, we assume 100.0 g of solution and use the given solution density to find the volume. Then we divide the amount (mol) of $\mathrm{H}_{2} \mathrm{O}_{2}$ [from part (a)] by solution volume (in L ).
SOLUTION (a) From mass \% to molality. Finding mass of solvent (assuming 100.0 g of solution):

$$
\text { Mass }(\mathrm{g}) \text { of } \mathrm{H}_{2} \mathrm{O}=100.0 \mathrm{~g} \text { solution }-30.0 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}_{2}=70.0 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}
$$

Converting from grams of $\mathrm{H}_{2} \mathrm{O}_{2}$ to moles:

$$
\text { Moles of } \mathrm{H}_{2} \mathrm{O}_{2}=30.0 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}_{2} \times \frac{1 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}_{2}}{34.02 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}_{2}}=0.882 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}_{2}
$$

Calculating molality:

$$
\text { Molality of } \mathrm{H}_{2} \mathrm{O}_{2}=\frac{0.882 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}_{2}}{70.0 \mathrm{~g} \times \frac{1 \mathrm{~kg}}{10^{3} \mathrm{~g}}}=12.6 \mathrm{~m} \mathrm{H}_{2} \mathrm{O}_{2}
$$

(b) From mass \% to mole fraction:

$$
\begin{aligned}
\text { Moles of } \mathrm{H}_{2} \mathrm{O}_{2} & =0.882 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}_{2} \text { [from part (a)] } \\
\text { Moles of } \mathrm{H}_{2} \mathrm{O} & =70.0 \mathrm{~g} \mathrm{H}_{2} \mathrm{O} \times \frac{1 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}}{18.02 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}}=3.88 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O} \\
X_{\mathrm{H}_{2} \mathrm{O}_{2}} & =\frac{0.882 \mathrm{~mol}}{0.882 \mathrm{~mol}+3.88 \mathrm{~mol}}=0.185
\end{aligned}
$$

(c) From mass $\%$ and density to molarity. Converting from solution mass to volume:

$$
\text { Volume }(\mathrm{mL}) \text { of solution }=100.0 \mathrm{~g} \times \frac{1 \mathrm{~mL}}{1.11 \mathrm{~g}}=90.1 \mathrm{~mL}
$$

Calculating molarity:

$$
\text { Molarity }=\frac{\mathrm{mol} \mathrm{H}_{2} \mathrm{O}_{2}}{\mathrm{~L} \text { soln }}=\frac{0.882 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}_{2}}{90.1 \mathrm{~mL} \times \frac{1 \mathrm{~L} \text { soln }}{10^{3} \mathrm{~mL}}}=9.79 \mathrm{M} \mathrm{H}_{2} \mathrm{O}_{2}
$$

CHECK Rounding shows the answers seem reasonable: (a) The ratio of $\sim 0.9 \mathrm{~mol} / 0.07 \mathrm{~kg}$ is greater than 10. (b) $\sim 0.9 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}_{2} /(1 \mathrm{~mol}+4 \mathrm{~mol}) \approx 0.2$. (c) The ratio of moles to liters $(0.9 / 0.09)$ is around 10 .

FOLLOW-UP PROBLEM 13.5 A sample of commercial concentrated hydrochloric acid is 11.8 M HCl and has a density of $1.190 \mathrm{~g} / \mathrm{mL}$. Calculate the mass $\%$, molality, and mole fraction of HCl .

## Section Summary

The concentration of a solution is independent of the amount of solution and can be expressed as molarity (mol solute/L solution), molality (mol solute/kg solvent), parts by mass (mass solute/mass solution), parts by volume (volume solute/volume solution), or mole fraction [mol solute/(mol solute +mol solvent)]. The choice of units depends on convenience or the nature of the solution. - If, in addition to the quantities of solute and solution, the solution density is also known, all ways of expressing concentration are interconvertible.

### 13.6 COLLIGATIVE PROPERTIES OF SOLUTIONS

We might expect the presence of solute particles to make the physical properties of a solution different from those of the pure solvent. However, what we might not expect is that, in the case of four important solution properties, the number of solute particles makes the difference, not their chemical identity. These properties, known as colligative properties (colligative means "collective"), are vapor pressure lowering, boiling point elevation, freezing point depression, and osmotic pressure. Even though most of these effects are small, they have many practical applications, including some that are vital to biological systems.

Historically, colligative properticsowermeaswed) to exprejthe natareof a solute in aqueous solution and its extent of dissociation into ions. In Chapter 4, we classified solutes by their ability to conduct an electric current, which requires moving ions to be present. Recall that an aqueous solution of an electrolyte conducts an electric current because the solute separates into ions as it dissolves. An electrolyte is classified as strong or weak depending on whether its solution is a good or poor conductor at moderate solute concentrations. Soluble salts, strong acids, and strong bases are strong electrolytes because they dissociate completely and, thus, their solutions conduct well. Weak acids and weak bases are weak electrolytes because they dissociate very little and, thus, their solutions conduct poorly. Many compounds, such as sugar and alcohol, do not dissociate into ions at all. They are nonelectrolytes because their solutions do not conduct a current. Figure 13.25 shows these behaviors.

A Strong electrolyte

B Weak electrolyte

C Nonelectrolyte

Figure 13.25 The three types of electrolytes. A, Strong electrolytes conduct a large current because they dissociate completely into ions. B, Weak electrolytes conduct a small current because they dissociate very little. C, Nonelectrolytes do not conduct a current because they do not dissociate.

To predict the magnitude of a colligative property, we refer to the solute formula to find the number of particles in solution. Each mole of nonelectrolyte yields 1 mol of particles in the solution. For example, 0.35 M glucose contains 0.35 mol of solute particles per liter. In principle, each mole of strong electrolyte dissociates into the number of moles of ions in the formula unit: $0.4 M \mathrm{Na}_{2} \mathrm{SO}_{4}$ contains 0.8 mol of $\mathrm{Na}^{+}$ions and 0.4 mol of $\mathrm{SO}_{4}{ }^{2-}$ ions, or 1.2 mol of particles, per liter (see Sample Problem 4.1, p. 143). (We examine the equilibrium nature of the dissociation of weak electrolytes in Chapters 18 and 19.)

## Colligative Properties of Nonvolatile Nonelectrolyte Solutions

In this section, we focus most of our attention on the simplest case, the colligative properties of solutes that do not dissociate into ions and have negligible vapor pressure even at the boiling point of the solvent. Such solutes are called nonvolatile nonelectrolytes; sucrose (table sugar) is an example. Later, we briefly explore the properties of volatile nonelectrolytes and of strong electrolytes.
Vapor Pressure Lowering The vapor pressure of a solution of a nonvolatile nonelectrolyte is always lower than the vapor pressure of the pure solvent. We can understand this vapor pressure lowering $(\boldsymbol{\Delta P})$ in terms of opposing rates and in terms of changes in entropy. Consider a pure solvent and the opposing rates of vaporization (molecules leaving the liquid) and of condensation (molecules re-entering the liquid). At equilibrium, the two rates are equal. When we add some nonvolatile solute, the number of solvent molecules on the surface is lower, so fewer vaporize per unit time. To maintain equilibrium, fewer gas molecules need to enter the liquid, and this occurs only if the concentration of gas, that is, the vapor pressure, is lowered. In terms of the entropy change, recall that natural processes occur in a direction of increasing entropy. A pure solvent vaporizes because the vapor has a
 greater entropy than it does as pure solvent, so it has less tendency to vaporize in order to gain entropy. Thus, by either argument, equilibrium is reached at a lower vapor pressure for the solution. Figure 13.26 illustrates this point.

In quantitative terms, we find that the vapor pressure of solvent above the solution $\left(P_{\text {solvent }}\right)$ equals the mole fraction of solvent in the solution $\left(X_{\text {solvent }}\right)$ times the vapor pressure of the pure solvent $\left(P_{\text {solvent }}^{\circ}\right)$. This relationship is expressed by Raoult's law:

$$
\begin{equation*}
P_{\text {solvent }}=X_{\text {solvent }} \times P_{\text {solvent }}^{\circ} \tag{13.9}
\end{equation*}
$$

In a solution, $X_{\text {solvent }}$ is always less than 1 , so $P_{\text {solvent }}$ is always less than $P_{\text {solvent }}^{\circ}$. An ideal solution is one that follows Raoult's law at any concentration. However, just as most gases deviate from ideality, so do most solutions. In practice, Raoult's law gives a good approximation of the behavior of dilute solutions only, and it becomes exact at infinite dilution.

How does the amount of solute affect the magnitude of the vapor pressure lowering, $\Delta P$ ? The solution consists of solvent and solute, so the sum of their mole fractions equals 1 :

$$
X_{\text {solvent }}+X_{\text {solute }}=1 ; \quad \text { thus, } \quad X_{\text {solvent }}=1-X_{\text {solute }}
$$

From Raoult's law, we have

$$
P_{\text {solvent }}=X_{\text {solvent }} \times P_{\text {solvent }}^{\circ}=\left(1-X_{\text {solute }}\right) \times P_{\text {solvent }}^{\circ}
$$

Multiplying through on the right side gives

$$
P_{\text {solvent }}=P_{\text {solvent }}^{\circ}-\left(X_{\text {solute }} \times P_{\text {solvent }}^{\circ}\right)
$$

Rearranging and introducing $\Delta P$ gives

$$
\begin{equation*}
P_{\text {solvent }}^{\circ}-P_{\text {solvent }}=\Delta P=X_{\text {solute }} \times P_{\text {solvent }}^{\circ} \tag{13.10}
\end{equation*}
$$

Thus, the magnitude of $\Delta P$ equals the mole fraction of solute times the vapor pressure of the pure solvent-a relationship applied in the next sample problem.

## SAMPLE PROBLEM 13.6 Using Raoult's Law to Find Vapor Pressure Lowering

PROBLEM Calculate the vapor pressure lowering, $\Delta P$, when 10.0 mL of glycerol $\left(\mathrm{C}_{3} \mathrm{H}_{8} \mathrm{O}_{3}\right)$ is added to $500 . \mathrm{mL}$ of water at $50 .{ }^{\circ} \mathrm{C}$. At this temperature, the vapor pressure of pure water is 92.5 torr and its density is $0.988 \mathrm{~g} / \mathrm{mL}$. The density of glycerol is $1.26 \mathrm{~g} / \mathrm{mL}$. PLAN To calculate $\Delta P$, we use Equation 13.10. We are given the vapor pressure of pure water $\left(P_{\mathrm{H}_{2} \mathrm{O}}^{\circ}=92.5\right.$ torr $)$, so we just need the mole fraction of glycerol, $X_{\text {glycerol }}$. We convert the given volume of glycerol ( 10.0 mL ) to mass using the given density ( $1.26 \mathrm{~g} / \mathrm{L}$ ), find the molar mass from the formula, and convert mass (g) to amount (mol). The same procedure gives amount of $\mathrm{H}_{2} \mathrm{O}$. From these, we find $X_{\mathrm{glyc}}$.
SOLUTION Calculating the amount (mol) of glycerol and of water:

$$
\begin{aligned}
\text { Moles of glycerol } & =10.0 \mathrm{~mL} \text { glycerol } \times \frac{1.26 \text { g glycerol }}{1 \mathrm{~mL} \text { glycerol }} \times \frac{1 \mathrm{~mol} \text { glycerol }}{92.09 \text { g glycerol }} \\
& =0.137 \mathrm{~mol} \text { glycerol } \\
\text { Moles of } \mathrm{H}_{2} \mathrm{O} & =500 . \mathrm{mL} \mathrm{H}_{2} \mathrm{O} \times \frac{0.988 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}}{1 \mathrm{~mL} \mathrm{H}_{2} \mathrm{O}} \times \frac{1 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}}{18.02 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}}=27.4 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

Calculating the mole fraction of glycerol:

$$
X_{\text {glycerol }}=\frac{0.137 \mathrm{~mol}}{0.137 \mathrm{~mol}+27.4 \mathrm{~mol}}=0.00498
$$

Finding the vapor pressure lowering:

$$
\Delta P=X_{\text {glycerol }} \times P_{\mathrm{H}_{2} \mathrm{O}}^{\circ}=0.00498 \times 92.5 \text { torr }=0.461 \text { torr }
$$

CHECK The amount of each component seems correct: for glycerol, $\sim 10 \mathrm{~mL} \times 1.25 \mathrm{~g} / \mathrm{mL}$ $\div 100 \mathrm{~g} / \mathrm{mol}=0.125 \mathrm{~mol}$; for $\mathrm{H}_{2} \mathrm{O}, \sim 500 \mathrm{~mL} \times 1 \mathrm{~g} / \mathrm{mL} \div 20 \mathrm{~g} / \mathrm{mol}=25 \mathrm{~mol}$. The small $\Delta P$ is reasonable because the mole fraction of solute is small.
COMMENT The calculation assumes that glycerol is nonvolatile. At 1 atm, glycerol boils at $290.0^{\circ} \mathrm{C}$, so the vapor pressure of glycerol at $50^{\circ} \mathrm{C}$ is so low it can be neglected.
FOLLOW-UP PROBLEM 13.6 Calculate the vapor pressure lowering of a solution of 2.00 g of aspirin $(\mathcal{M}=180.15 \mathrm{~g} / \mathrm{mol})$ in 50.0 g of methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ at $21.2^{\circ} \mathrm{C}$. Pure methanol has a vapor pressure of 101 torr at this temperature.

Boiling Point Elevation A solution boils at a higher temperature than the pure solvent. Let's see why. The boiling point (boiling temperature, $T_{\mathrm{b}}$ ) of a liquid is the temperature at which its vapor pressure equals the external pressure. The vapor pressure of a solution is lower than the external pressure at the solvent's boiling point because the vapor pressure of a solution is lower than that of the pure solvent at any temperature. Therefore, the solution does not yet boil. A higher temperature is needed to raise the solution's vapor pressure to equal the external pressure. We can see this boiling point elevation $\left(\boldsymbol{\Delta} \boldsymbol{T}_{\mathbf{b}}\right)$ by superimposing a phase diagram for the solution on a phase diagram for the pure solvent, as shown in

## Volume $(\mathrm{mL})$ of glycerol (or $\mathrm{H}_{2} \mathrm{O}$ )

multiply by density ( $\mathrm{g} / \mathrm{mL}$ )

Mass ( g ) of glycerol (or $\mathrm{H}_{2} \mathrm{O}$ )
divide by $\mu(\mathrm{g} / \mathrm{mol})$

Amount (mol) of glycerol (or $\mathrm{H}_{2} \mathrm{O}$ )
divide by total number of moles

Mole fraction ( $\boldsymbol{X}$ ) of glycerol
multiply by $P_{\mathrm{H}_{2} \mathrm{O}}^{\circ}$

Vapor pressure lowering ( $\Delta P$ )

Figure 13.27 Phase diagrams of solvent and solution. Phase diagrams of an aqueous solution (dashed lines) and of pure water (solid lines) show that, by lowering the vapor pressure $(\Delta P)$, a dissolved solute elevates the boiling point ( $\Delta T_{\mathrm{b}}$ ) and depresses the freezing point $\left(\Delta T_{f}\right)$.

Figure 13.27. Note that the gas-liquid line for the solution lies below that for the pure solvent at any temperature and to the right of it at any pressure.

Like the vapor pressure lowering, the magnitude of the boiling point elevation is proportional to the concentration of solute particles:

$$
\begin{equation*}
\Delta T_{\mathrm{b}} \propto m \text { or } \Delta T_{\mathrm{b}}=K_{\mathrm{b}} m \tag{13.11}
\end{equation*}
$$

where $m$ is the solution molality, $K_{\mathrm{b}}$ is the molal boiling point elevation constant,
 value, so we subtract the lower temperature from the higher; that is, we subtract the solvent $T_{\mathrm{b}}$ from the solution $T_{\mathrm{b}}$ :

$$
\Delta T_{\mathrm{b}}=T_{\mathrm{b}(\text { solution })}-T_{\mathrm{b} \text { (solvent })}
$$

Molality is the concentration term used because it is related to mole fraction and thus to particles of solute. It also involves mass rather than volume of solvent, so it is not affected by temperature changes. The constant $K_{\mathrm{b}}$ has units of degrees Celsius per molal unit ( ${ }^{\circ} \mathrm{C} / m$ ) and is specific for a given solvent (Table 13.6).

Notice that the $K_{\mathrm{b}}$ for water is only $0.512^{\circ} \mathrm{C} / \mathrm{m}$, so the changes in boiling point are quite small: if you dissolved 1.00 mol of glucose $(180 . \mathrm{g} ; 1.00 \mathrm{~mol}$ of particles) in 1.00 kg of water, or 0.500 mol of $\mathrm{NaCl}(29.2 \mathrm{~g}$; a strong electrolyte, so also 1.00 mol of particles) in 1.00 kg of water, the boiling points of the resulting solutions at 1 atm would be only $100.512^{\circ} \mathrm{C}$ instead of $100.000^{\circ} \mathrm{C}$.

## Table 13.6 Molal Boiling Point Elevation and Freezing Point Depression Constants of Several Solvents

| Solvent | Boiling Point $\left({ }^{\circ} \mathrm{C}\right)^{*}$ | $\boldsymbol{K}_{\mathrm{b}}\left({ }^{\circ} \mathrm{C} / \mathbf{m}\right)$ | Melting Point $\left({ }^{\circ} \mathrm{C}\right)$ | $\boldsymbol{K}_{\mathrm{f}}\left({ }^{\circ} \mathrm{C} / \mathbf{m}\right)$ |
| :--- | :---: | :---: | :---: | :---: |
| Acetic acid | 117.9 | 3.07 | 16.6 | 3.90 |
| Benzene | 80.1 | 2.53 | 5.5 | 4.90 |
| Carbon disulfide | 46.2 | 2.34 | -111.5 | 3.83 |
| Carbon tetrachloride | 76.5 | 5.03 | -23 | 30. |
| Chloroform | 61.7 | 3.63 | -63.5 | 4.70 |
| Diethyl ether | 34.5 | 2.02 | -116.2 | 1.79 |
| Ethanol | 78.5 | 1.22 | -117.3 | 1.99 |
| Water | 100.0 | 0.512 | 0.0 | 1.86 |

*At 1 atm.

Freezing Point Depression As you just saw, only solvent molecules can vaporize from the solution, so molecules of the nonvolatile solute are left behind. Similarly, in many cases, only solvent molecules can solidify, again leaving solute molecules behind to form a slightly more concentrated solution. The freezing point of a solution is that temperature at which its vapor pressure equals that of the pure solvent. At this temperature, the two phases-solid solvent and liquid solution-are in equilibrium. Because the vapor pressure of the solution is lower than that of the solvent at any temperature, the solution freezes at a lower temperature than the solvent. In other words, the numbers of solvent particles leaving and entering the solid per unit time become equal at a lower temperature. The freezing point depression $\left(\boldsymbol{\Delta} \boldsymbol{T}_{\mathrm{f}}\right)$ is shown in Figure 13.27; note that the solid-liquid line for the solution lies to the left of that for the pure solvent at any pressure.

Like $\Delta T_{\mathrm{b}}$, the freezing point depression has a magnitude proportional to the molal concentration of solute:

$$
\begin{equation*}
\Delta T_{\mathrm{f}} \propto m \text { or } \Delta T_{\mathrm{f}}=K_{\mathrm{f}} m \tag{13.12}
\end{equation*}
$$

where $K_{\mathrm{f}}$ is the molal freezing point depression constant, which also has units of ${ }^{\circ} \mathrm{C} / m$ (see Table 13.6). Also like $\Delta T_{\mathrm{b}}, \Delta T_{\mathrm{f}}$ is considered a positive value, so we subtract the lower temperature from the higher; in this case, however, it is the solution $T_{\mathrm{f}}$ from the solvent $T_{\mathrm{f}}$ :

$$
\Delta T_{\mathrm{f}}=T_{\mathrm{f}(\text { solvent })}-T_{\mathrm{f}(\text { solution })}
$$

Here, too, the overall effect in aqueous solution is quite small because the $K_{\mathrm{f}}$ value for water is small-only $1.86^{\circ} \mathrm{C} / \mathrm{m}$. Thus, 1 m glucose, 0.5 m NaCl , and $0.33 m \mathrm{~K}_{2} \mathrm{SO}_{4}$, all solutions with 1 mol of particles per kilogram of water, freeze at $-1.86^{\circ} \mathrm{C}$ at 1 atm instead of at $0.00^{\circ} \mathrm{C}$.

## SAMPLE PROBLEM 13.7 Determining the Boiling Point Elevation and Freezing Point Depression of a Solution

PROBLEM You add 1.00 kg of ethylene glycol $\left(\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}\right)$ antifreeze to your car radiator, which contains 4450 g of water. What are the boiling and freezing points of the solution? PLAN To find the boiling and freezing points of the solution, we first find the molality by converting the given mass of solute ( 1.00 kg ) to amount (mol) and dividing by mass of solvent ( 4450 g ). Then we calculate $\Delta T_{\mathrm{b}}$ and $\Delta T_{\mathrm{f}}$ from Equations 13.11 and 13.12 (using constants from Table 13.6). We add $\Delta T_{\mathrm{b}}$ to the solvent boiling point and subtract $\Delta T_{\mathrm{f}}$ from the solvent freezing point. The roadmap shows the steps.
SOLUTION Calculating the molality:

$$
\begin{aligned}
\text { Moles of } \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2} & =1.00 \mathrm{~kg} \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2} \times \frac{10^{3} \mathrm{~g}}{1 \mathrm{~kg}} \times \frac{1 \mathrm{~mol} \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}}{62.07 \mathrm{~g} \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}}=16.1 \mathrm{~mol} \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2} \\
\text { Molality } & =\frac{\text { mol solute }}{\mathrm{kg} \text { solvent }}=\frac{16.1 \mathrm{~mol} \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}}{4450 \mathrm{~g} \mathrm{H}_{2} \mathrm{O} \times \frac{1 \mathrm{~kg}}{10^{3} \mathrm{~g}}}=3.62 \mathrm{~m} \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}
\end{aligned}
$$

Finding the boiling point elevation and $T_{\mathrm{b} \text { (solution), }}$, with $K_{\mathrm{b}}=0.512^{\circ} \mathrm{C} / \mathrm{m}$ :

$$
\begin{gathered}
\Delta T_{\mathrm{b}}=\frac{0.512^{\circ} \mathrm{C}}{m} \times 3.62 \mathrm{~m}=1.85^{\circ} \mathrm{C} \\
T_{\mathrm{b} \text { (solution) }}=T_{\mathrm{b}(\text { solvent })}+\Delta T_{\mathrm{b}}=100.00^{\circ} \mathrm{C}+1.85^{\circ} \mathrm{C}=101.85^{\circ} \mathrm{C}
\end{gathered}
$$

Finding the freezing point depression and $T_{\mathrm{f} \text { (solution) })}$, with $K_{\mathrm{f}}=1.86^{\circ} \mathrm{C} / \mathrm{m}$ :

$$
\begin{gathered}
\Delta T_{\mathrm{f}}=\frac{1.86^{\circ} \mathrm{C}}{m} \times 3.62 \mathrm{~m}=6.73^{\circ} \mathrm{C} \\
T_{\mathrm{f}(\text { solution })}=T_{\mathrm{f} \text { (solvent) }}-\Delta T_{\mathrm{f}}=0.00^{\circ} \mathrm{C}-6.73^{\circ} \mathrm{C}=-6.73^{\circ} \mathrm{C}
\end{gathered}
$$

CHECK The changes in boiling and freezing points should be in the same proportion as the constants used. That is, $\Delta T_{\mathrm{b}} / \Delta T_{\mathrm{f}}$ should equal $K_{\mathrm{b}} / K_{\mathrm{f}}: 1.85 / 6.73=0.275=0.512 / 1.86$. COMMENT These answers are only approximate because the concentration far exceeds that
of a dilute solution, for which Raoult's law is most useful. of a dilute solution, for which Raoult's law is most useful.

FOLLOW-UP PROBLEM 13.7 What is the minimum concentration (molality) of ethylene glycol solution that will protect the car's cooling system from freezing at $0.00^{\circ} \mathrm{F}$ ? (Assume the solution is ideal.)

Osmotic Pressure The fourth colligative property appears when two solutions of different concentrations are separated by a semipermeable membrane, one that allows solvent, but not solute, molecules to pass through. This phenomenon is called osmosis. Many organisms have semipermeable membranes that regulate internal concentrations by osmosis, and synthetic polymers are studied by osmosis.

Consider a simple apparatus in which a semipermeable membrane lies at the curve of a U tube and separates an aqueous sugar solution from pure water. The membrane allows water molecules to pass in either direction, but not the larger sugar molecules. Because the solute molecules are present, fewer water molecules touch the membrane on the solution side, so fewer of them leave the solution in a given time than enter it (Figure 13.28A). This net flow of water into the solution increases the volume of the solution and thus decreases its concentration.

As the height of the solution rises and that of the solvent falls, the resulting pressure difference pushes some water molecules from the solution back through the membrane. At equilibrium, water is pushed out of the solution at the same rate it enters (Figure 13.28B). The pressure difference at equilibrium is the osmotic pressure ( $\Pi$ ), which is defined as the applied pressure required to prevent the net movement of water from solvent to solution (Figure 13.28C).

The osmotic pressure is proportional to the number of solute particles in a given volume of solution, that is, to the molarity ( $M$ ):

$$
\Pi \propto \frac{n_{\text {solute }}}{V_{\text {soln }}} \quad \text { or } \quad \Pi \propto M
$$

$$
\begin{equation*}
\Pi=\frac{n_{\text {solute }}}{V_{\text {soln }}} R T=M R T \tag{13.13}
\end{equation*}
$$

The similarity of Equation 13.13 to the ideal gas law ( $P=n R T / V$ ) is not surprising, because both relate the pressure of a system to its concentration and temperature. The Gallery shows some important applications of colligative properties.

Figure 13.28 The development of osmotic pressure. A, In the process of osmosis, a solution and a solvent (or solutions of different concentrations) are separated by a semipermeable membrane, which allows only solvent molecules to pass through. The molecularscale view (below) shows that more solvent molecules enter the solution than leave it in a given time. B, As a result, the solution volume increases, so its concentration decreases. At equilibrium, the difference in heights in the two compartments reflects the osmotic pressure (II). The greater height in the solution compartment exerts a backward pressure that eventually equalizes the flow of solvent in both directions. C, Osmotic pressure is defined as the applied pressure required to prevent this volume change.

## Colligative Properties in Industry and Biology

Colligative properties-especially freezing point depression and osmotic pressure-have much practical relevance to everyday life. Some common applications of freezing point depression make life safer during cold winter months. Others are essential to the electronics industry. Applications of osmotic pressure are found throughout nature and in the health and biological sciences-without question, the most important semipermeable membranes surround living cells.

## Applications of Freezing Point Depression

Plane de-icing and car antifreezing Ethylene glycol $\left(\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}\right)$ is miscible with water through extensive hydrogen bonding and has a high enough boiling point for it to be essentially nonvolatile at $100^{\circ} \mathrm{C}$. It is the major ingredient in airplane "de-icers." In "year-round" automobile antifreeze, it lowers the freezing point of water in the radiator in the winter and raises its boiling point in the summer.

Biological antifreeze To survive in the Arctic and in northern winters, many fish and insects, including the common housefly, produce large amounts of glycerol $\left(\mathrm{C}_{3} \mathrm{H}_{8} \mathrm{O}_{3}\right)$-a substance with a structure very similar to that of ethylene glycol and also miscible with water-which lowers the freezing point of their blood.

## Zone refining

Manufacturing computer chips requires extremely pure starting materials. In the process of zone refining, a rod of impure silicon (or other metal or metalloid) is passed slowly through a heating coil in an inert atmosphere, and the first narrow zone of impure solid
melts. As the next zone melts, the dissolved impurities from the first zone lower the freezing point of the solution, while the purer solvent refreezes. The process continues, zone by zone, throughout the entire rod. After several passes through the coil, in which each zone's impurities move into the adjacent zone, the refrozen silicon at the end of the rod becomes extremely pure-more than $99.999999 \%$. The ultrapure silicon is then sliced into wafers for the production of computer chips (Section 12.7).

Controlling cell shape The word tonicity refers to the tone, or firmness of a biological cell. An isotonic solution has the same concentration of particles as in the cell fluid, so water enters the cell at the same rate that it leaves, thereby maintaining the cell's normal shape.

To study cell contents, biochemists rupture membranes by placing the cell in a hypotonic solution, one that has a lower concentration of solute particles than the cell fluid. As a result, water enters the cell faster than it leaves, causing the cell to expand and burst.

In a hypertonic solution, one that contains a higher concentration of solute particles than the cell fluid, the cell shrinks from the net outward flow of water.

Isotonic daily care Contact-lens rinses consist of isotonic saline ( 0.15 M NaCl ) to prevent any changes in the volume of corneal cells. Solutions for the intravenous delivery of nutrients or drugs are always isotonic.

Hypotonic watering of trees The dissolved substances in tree sap create a more concentrated solution than the surrounding groundwater. Water enters membranes in the roots and rises into the tree, creating an osmotic pressure that can exceed 20 atm in the tallest trees!

Sodium ion: the extracellular osmoregulator Of the four major biological cations- $\mathrm{Na}^{+}, \mathrm{K}^{+}, \mathrm{Mg}^{2+}$, and $\mathrm{Ca}^{2+}-\mathrm{Na}^{+}$is essential for all animals (which includes you!) to regulate their fluid volume. The $\mathrm{Na}^{+}$ion accounts for more than $90 \mathrm{~mol} \%$ of all cations outside a cell. A high $\mathrm{Na}^{+}$concentration draws water out of the cell by osmosis; a low $\mathrm{Na}^{+}$concentration leaves more
 inside. The primary role of $\mathrm{Na}^{+}$is to regulate the water volume of the body, and the primary role of the kidneys is to regulate the concentration of $\mathrm{Na}^{+}$. Changes in blood pressure (volume) activate nerves and hormones to adjust blood flow and alter kidney function.

Hypertonic food preservation Before refrigeration was common, salt was used as a preservative. The salt causes microbes on the food's surface to shrivel and die from loss of water. (Salt was so highly prized for this purpose that Roman soldiers were paid in salt, from which practice comes the word salary.) In 1772, Captain James Cook wisely brought on board his ship large amounts of cabbage as food stores and preserved it with salt, thus converting the perishable vegetable into long-lived sauerkraut. The high vitamin-C content of the
 pickled cabbage prevented the debilitating effects of scurvy and allowed Cook's crew to continue explorations and partake in experiments that would revolutionize longitude measurements and, thus, oceangoing navigation.

The Underlying Theme of Colligative Properties A common theme runs through our explanations of the four colligative properties of nonvolatile solutes. Each property rests on the inability of solute particles to cross between two phases. Solute particles cannot enter the gas phase, which leads to vapor pressure lowering and boiling point elevation. They cannot enter the solid phase, which leads to freezing point depression. They cannot cross a semipermeable membrane, which leads to the development of osmotic pressure. The presence of solute decreases the mole fraction of solvent, which lowers the number of solvent particles leaving the solution per unit time; this lowering requires an adjustment to reach equilibrium again. This adjustment to reach the new balance in numbers of particles crossing between two phases per unit time results in the measured colligative property.

## Using Colligative Properties to Find Solute Molar Mass

Each colligative property relates concentration to some measurable quantity-the number of degrees the freezing point is lowered, the magnitude of osmotic pressure created, and so forth. From these measurements, we can determine the amount (mol) of solute particles and, for a known mass of solute, the molar mass of the solute as well.

In principle, any of the colligative properties can be used to find the solute's molar mass, but in practice, some systems provide more accurate data than others. For example, to determine the molar mass of an unknown solute by freezing point depression, you would select a solvent with as large a molal freezing point depression constant as possible (see Table 13.6). If the solute is soluble in acetic acid, for instance, a 1 m concentration of it depresses the freezing point of acetic acid by $3.90^{\circ} \mathrm{C}$, more than twice the change in water $\left(1.86^{\circ} \mathrm{C}\right)$.

Of the four colligative properties, osmotic pressure creates the largest changes and therefore the most precise measucement. Biodgieal andidymen chemists estimate molar masses as great as $10^{5} \mathrm{~g} / \mathrm{mol}$ by measuring osmotic pressure. Because only a tiny fraction of a mole of a macromolecular solute dissolves, it would create too small a change in the other colligative properties.

## SAMPLE PROBLEM 13.8 Determining Molar Mass from Osmotic Pressure

PROBLEM Biochemists have discovered more than 400 mutant varieties of hemoglobin, the blood protein that carries oxygen throughout the body. A physician studying a variety associated with a fatal disease first finds its molar mass ( $\mathcal{M}$ ). She dissolves 21.5 mg of the protein in water at $5.0^{\circ} \mathrm{C}$ to make 1.50 mL of solution and measures an osmotic pressure of 3.61 torr. What is the molar mass of this variety of hemoglobin?
PLAN We know the osmotic pressure $\left(\Pi=3.61\right.$ torr), $R$, and $T\left(5.0^{\circ} \mathrm{C}\right)$. We convert $\Pi$ from torr to atm, and $T$ from ${ }^{\circ} \mathrm{C}$ to K , and then use Equation 13.13 to solve for molarity $(M)$. Then we calculate the amount (mol) of hemoglobin from the known volume $(1.50 \mathrm{~mL})$ and use the known mass ( 21.5 mg ) to find $\mathcal{M}$.
SOLUTION Combining unit conversion steps and solving for molarity from Equation 13.13:

$$
M=\frac{\Pi}{R T}=\frac{\frac{3.61 \text { torr }}{760 \mathrm{torr} / 1 \mathrm{~atm}}}{\left(0.0821 \frac{\mathrm{~atm} \cdot \mathrm{~L}}{\mathrm{~mol} \cdot \mathrm{~K}}\right)(273.15 \mathrm{~K}+5.0)}=2.08 \times 10^{-4} \mathrm{M}
$$

Finding amount (mol) of solute (after changing mL to L ):

$$
\text { Moles of solute }=M \times V=\frac{2.08 \times 10^{-4} \mathrm{~mol}}{1 \mathrm{~L} \text { soln }} \times 0.00150 \mathrm{~L} \text { soln }=3.12 \times 10^{-7} \mathrm{~mol}
$$

Calculating molar mass of hemoglobin (after changing mg to g ):

$$
\mathcal{M}=\frac{0.0215 \mathrm{~g}}{3.12 \times 10^{-7} \mathrm{~mol}}=6.89 \times 10^{4} \mathrm{~g} / \mathrm{mol}
$$

CHECK The answers seem reasonable: The small osmotic pressure implies a very low molarity. Hemoglobin is a protein, a biological macromolecule, so we expect a small number of moles $\left[\left(\sim 2 \times 10^{-4} \mathrm{~mol} / \mathrm{L}\right)\left(1.5 \times 10^{-3} \mathrm{~L}\right)=3 \times 10^{-7} \mathrm{~mol}\right]$ and a high molar mass $\left(\sim 21 \times 10^{-3} \mathrm{~g} / 3 \times 10^{-7} \mathrm{~mol}=7 \times 10^{4} \mathrm{~g} / \mathrm{mol}\right)$.
FOLLOW-UP PROBLEM 13.8 A 0.30 M solution of sucrose that is at $37^{\circ} \mathrm{C}$ has approximately the same osmotic pressure as blood does. What is the osmotic pressure of blood?

## Colligative Properties of Volatile Nonelectrolyte Solutions

What is the effect on vapor pressure when the solute is volatile, that is, when the vapor consists of solute and solvent molecules? From Raoult's law (Equation 13.9), we know that

$$
P_{\text {solvent }}=X_{\text {solvent }} \times P_{\text {solvent }}^{\circ} \text { and } P_{\text {solute }}=X_{\text {solute }} \times P_{\text {solute }}^{\circ}
$$

where $X_{\text {solvent }}$ and $X_{\text {solute }}$ refer to the mole fractions in the liquid phase. According to Dalton's law of partial pressures, the total vapor pressure is the sum of the partial vapor pressures:

$$
P_{\text {total }}=P_{\text {solvent }}+P_{\text {solute }}=\left(X_{\text {solvent }} \times P_{\text {solvent }}^{\circ}\right)+\left(X_{\text {solute }} \times P_{\text {solute }}^{\circ}\right)
$$

Just as a nonvolatile solute lowers the vapor pressure of the solvent by making the mole fraction of the solvent less than 1 , the presence of each volatile component lowers the vapor pressure of the other by making each mole fraction less than 1.

Let's examine this effect in a solution that contains equal amounts (mol) of
 pressure of pure benzene $\left(P_{\text {ben }}^{\circ}\right)$ is 95.1 torr and that of pure toluene $\left(P_{\text {tol }}^{\circ}\right)$ is 28.4 torr; note that benzene is more volatile than toluene. We find the partial pressures from Raoult's law:

$$
\begin{aligned}
P_{\text {ben }} & =X_{\text {ben }} \times P_{\text {ben }}^{\circ}=0.500 \times 95.1 \text { torr }=47.6 \text { torr } \\
P_{\mathrm{tol}} & =X_{\mathrm{tol}} \times P_{\mathrm{tol}}^{\circ}=0.500 \times 28.4 \text { torr }=14.2 \text { torr }
\end{aligned}
$$

As you can see, the presence of benzene lowers the vapor pressure of toluene, and vice versa.

Does the composition of the vapor differ from that of the solution? To see, let's calculate the mole fraction of each substance in the vapor by applying Dalton's law. Recall from Section 5.4 that $X_{\mathrm{A}}=P_{\mathrm{A}} / P_{\text {total }}$. Therefore, for benzene and toluene in the vapor,

$$
\begin{aligned}
& X_{\text {ben }}=\frac{P_{\text {ben }}}{P_{\text {total }}}=\frac{47.6 \text { torr }}{47.6 \text { torr }+14.2 \text { torr }}=0.770 \\
& X_{\text {tol }}=\frac{P_{\text {tol }}}{P_{\text {total }}}=\frac{14.2 \text { torr }}{47.6 \text { torr }+14.2 \text { torr }}=0.230
\end{aligned}
$$

The vapor composition is very different from the solution composition. The essential point to notice is that the vapor has a higher mole fraction of the more volatile solution component. The 50/50 ratio of benzene to toluene in the liquid created a 77/23 ratio of benzene to toluene in the vapor. Condense this vapor into a separate container, and that new solution would have this $77 / 23$ composition, and the new vapor above it would be enriched still further in benzene.

In the process of fractional distillation, this phenomenon is used to separate a mixture of volatile components. Numerous vaporization-condensation steps continually enrich the vapor, until the vapor reaching the top of the fractionating column consists solely of the most volatile component. Figure 13.29 shows how
fractional distillation is used in the industrial process of petroleum refining to separate the hundreds of individual compounds in crude oil into a small number of "fractions" based on boiling point range.

## Colligative Properties of Strong Electrolyte Solutions

When we consider colligative properties of strong electrolyte solutions, the solute formula tells us the number of particles. For instance, the boiling point elevation $\left(\Delta T_{\mathrm{b}}\right)$ of 0.050 m NaCl should be twice that of 0.050 m glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$, because NaCl dissociates into two particles per formula unit. Thus, we include a multiplying factor in the equations for the colligative properties of electrolyte solutions. The van't Hoff factor ( $i$ ), named after the Dutch chemist Jacobus van't Hoff (1852-1911), is the ratio of the measured value of the colligative property in the electrolyte solution to the expected value for a nonelectrolyte solution:

$$
i=\frac{\text { measured value for electrolyte solution }}{\text { expected value for nonelectrolyte solution }}
$$

To calculate the colligative properties of strong electrolyte solutions, we incorporate the van't Hoff factor into the equation:

$$
\begin{array}{ll}
\text { For vapor pressure lowering: } & \Delta P=i\left(X_{\text {solute }} \times P_{\text {solvent }}^{\circ}\right) \\
\text { For boiling point elevation: } & \Delta T_{\mathrm{b}}=i\left(K_{\mathrm{b}} m\right) \\
\text { For freezing point depression: } & \Delta T_{\mathrm{f}}=i\left(K_{\mathrm{f}} m\right) \\
\text { For osmotic pressure: } & \Pi=i(M R T)
\end{array}
$$

If strong electrolyte solutions behaved ideally, the factor $i$ would be the amount (mol) of particles in solution divided by the amount (mol) of dissolved solute; that is, $i$ would be 2 for $\mathrm{NaCl}, 3$ for $\mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}$, and so forth. Careful experiment shows, however, that moststrong electrgtyter sotytions are not ideal. For example, comparing the boiling point=elevation for 0.050 m NaCt solution with that for 0.050 m glucose solution gives a factor $i$ of 1.9 , not 2.0:

$$
i=\frac{\Delta T_{\mathrm{b}} \text { of } 0.050 \mathrm{~m} \mathrm{NaCl}}{\Delta T_{\mathrm{b}} \text { of } 0.050 \mathrm{~m} \text { glucose }}=\frac{0.049^{\circ} \mathrm{C}}{0.026^{\circ} \mathrm{C}}=1.9
$$

The measured value of the van't Hoff factor is typically lower than that expected from the formula. This deviation implies that the ions are not behaving as independent particles. However, we know from other evidence that soluble salts dissociate completely into ions. The fact that the deviation is greater with multiply charged ions is a strong indication that the ionic charge is somehow involved (Figure 13.30).

To explain this nonideal behavior, we picture ions as separate but near each other. Clustered near a positive ion are, on average, more negative ions than positive ones, and vice versa. Figure 13.31 shows each ion surrounded by an ionic atmosphere of net opposite charge. Through these electrostatic associations, each type of ion behaves as if it were "tied up," so its concentration seems lower than it actually is. Thus, we often speak of an effective concentration, obtained by multiplying $i$ by the stoichiometric concentration based on the formula. The greater the charge, the stronger the electrostatic associations; so the deviation from ideal behavior is greater for compounds that dissociate into multiply charged ions.

At ordinary conditions and concentrations, nonideal behavior of solutions is much more common (and the deviations much larger) than nonideal behavior of gases, because the particles in solutions are so much closer together. Nevertheless, the two systems exhibit some interesting similarities. Gases display nearly ideal behavior at low pressures because the distances between particles are large. Similarly, van't Hoff factors (i) approach their ideal values as the solution becomes more dilute, that is, as the distance between ions increases. In gases, attractions between particles cause deviations from the expected pressure. In solutions,

Figure 13.30 Nonideal behavior of strong electrolyte solutions. The van't Hoff factors (i) for various ionic solutes in dilute $(0.05 \mathrm{~m})$ aqueous solution show that the observed value (dark blue) is always lower than the expected value (light blue). This deviation is due to ionic interactions that, in effect, reduce the number of free ions in solution. The deviation is greatest for multiply charged ions.

Figure 13.31 An ionic atmosphere model for nonideal behavior of electrolyte solutions. Hydrated anions cluster near cations, and vice versa, to form ionic atmospheres of net opposite charge. Because the ions do not act independently, their concentrations are effectively less than expected. Such interactions cause deviations from ideal behavior.
attractions between particles cause deviations from the expected size of a colligative property. Finally, for both real gases and real solutions, we use empirically determined numbers (van der Waals constants or van't Hoff factors) to transform theories (the ideal gas law or Raoult's law) into more useful relations.

## SAMPLE PROBLEM 13.9 Finding Colligative Properties

 from Molecular ScenesPROBLEM A $0.952-\mathrm{g}$ sample of magnesium chloride is dissolved in 100 g of water in a flask. (a) Which scene depicts the solution best?

(b) What is the amount (mol) represented by each green sphere?
(c) Assuming the solution is ideal, what is its freezing point (at 1 atm )?

PLAN (a) From the name, we recognize an ionic compound, so we determine the formula to find the numbers of cations and anions per formula unit and compare this result with the three scenes: there is 1 magnesium ion for every 2 chloride ions. (b) From the given mass of solute, we find the amount (mol); from part (a), there are twice as many moles of chloride ions (green spheres). Dividing by the total number of green spheres gives the moles/sphere. (c) From the moles of solute and the given mass (kg) of water, we find the molality ( $m$ ). We use $K_{\mathrm{f}}$ for water from Table 13.6 and multiply by $m$ to get $\Delta T_{\mathrm{f}}$, and then subtract that from $0.000^{\circ} \mathrm{C}$ to get the solution freezing point.
SOLUTION (a) The formula is $\mathrm{MgCl}_{2}$; only scene A has $1 \mathrm{Mg}^{2+}$ for every $2 \mathrm{Cl}^{-}$.
(b)

$$
\text { Moles of } \mathrm{MgCl}_{2}=\frac{0.952 \mathrm{~g} \mathrm{MgCl}_{2}}{95.21 \mathrm{~g} / \mathrm{mol} \mathrm{MgCl}_{2}}=0.0100 \mathrm{~mol} \mathrm{MgCl} 2
$$

Therefore, $\quad$ Moles of $\mathrm{Cl}^{-}=0.0100 \mathrm{~mol} \mathrm{MgCl} 2 \times \frac{2 \mathrm{Cl}^{-}}{1 \mathrm{MgCl}_{2}}=0.0200 \mathrm{~mol} \mathrm{Cl}^{-}$

$$
\text { Moles } / \text { sphere }=\frac{0.0200 \mathrm{~mol} \mathrm{Cl}^{-}}{8 \text { spheres }}=2.50 \times 10^{-3} \mathrm{~mol} / \text { sphere }
$$

(c) Molality $(m)=\frac{\mathrm{mol} \text { of solute }}{\mathrm{kg} \text { of solvent }}=\frac{0.0100 \mathrm{~mol} \mathrm{MgCl}_{2}}{100 . \mathrm{g} \times \frac{1 \mathrm{~kg}}{1000 \mathrm{~g}}}=0.100 m \mathrm{MgCl}_{2}$

Assuming an ideal solution, the van't Hoff factor, $i$, is 3 for $\mathrm{MgCl}_{2}$ because there are 3 ions per formula unit, so we have
and

$$
\Delta T_{\mathrm{f}}=i\left(K_{\mathrm{f}} m\right)=3\left(1.86^{\circ} \mathrm{C} / m \times 0.100 \mathrm{~m}\right)=0.558^{\circ} \mathrm{C}
$$

CHECK Let's quickly check part (c): We have 0.01 mol dissolved in 0.1 kg , which gives 0.1 m . Then, rounding $K_{\mathrm{f}}$, we have about $3\left(2^{\circ} \mathrm{C} / m \times 0.1 \mathrm{~m}\right)=0.6^{\circ} \mathrm{C}$.

FOLLOW-UP PROBLEM 13.9 The $\mathrm{MgCl}_{2}$ solution in the sample problem has a density of $1.006 \mathrm{~g} / \mathrm{mL}$ at $20.0^{\circ} \mathrm{C}$. (a) What is the osmotic pressure of the solution? (b) A U-tube fitted with a semipermeable membrane is filled with this $\mathrm{MgCl}_{2}$ solution in the left arm and a glucose solution of equal molarity in the right arm. After time, which scene depicts the U-tube best?

#### Abstract

Section Summary Colligative properties are related to the number of dissolved solute particles, not their chemical nature. - Compared with the pure solvent, a solution of a nonvolatile nonelectrolyte has a lower vapor pressure (Raoult's law), an elevated boiling point, a depressed freezing point, and an osmotic pressure. - Colligative properties can be used to determine the solute molar mass. - When solute and solvent are volatile, the vapor pressure of each is lowered by the presence of the other. The vapor pressure of the more volatile component is always higher. - Electrolyte solutions exhibit nonideal behavior because ionic interactions reduce the effective concentration of the ions.

### 13.7 THE STRUCTURE AND PROPERTIES OF COLLOIDS

Stir a handful of fine sand into a glass of water, and you'll see the sand particles are suspended at first but gradually settle to the bottom. Sand in water is a suspension, a heterogeneous mixture containing particles large enough to be seen by the naked eye and clearly distinct from the surrounding fluid. In contrast, stirring sugar into water forms a solution, a homogeneous mixture in which the particles are individual molecules distributed evenly throughout the surrounding fluid.

Between the extremes of suspensions and solutions is a large group of mixtures called colloidal dispersions, or colloids, in which a dispersed (solute-like) substance is distributed throughout a dispersing (solvent-like) substance. Colloidal particles are larger than simple molecules but small enough to remain distributed and not settle out. They range in diameter from 1 to $1000 \mathrm{~nm}\left(10^{-9}\right.$ to $\left.10^{-6} \mathrm{~m}\right)$. A colloidal particle may consist of a single macromolecule (such as a protein or synthetic polymer) or an aggregate of many atoms, ions, or molecules. Whatever their composition, colloidal particles have an enormous total surface area as a result of their small size. A cubeAphacgin sides bis a FotalkifaceClealof $6 \mathrm{~cm}^{2}$. If it's divided equally into $10^{\text {12 }}$ cubes, the cubes are the size of large colloidal particles and have a total surface area of $60,000 \mathrm{~cm}^{2}$, or $6 \mathrm{~m}^{2}$. This enormous surface area allows many more interactions to exert a great total adhesive force, which attracts other particles and leads to the practical uses of colloids.

Colloids are classified in Table 13.7 according to whether the dispersed and dispersing substances are gases, liquids, or solids. Many familiar commercial products and natural objects are colloids. Whipped cream is a foam, a gas dispersed in a liquid. Firefighting foams are liquid mixtures of proteins in water that are made frothy with fine jets of air. Most biological fluids are aqueous sols, solids dispersed in water. Within a typical cell, proteins and nucleic acids are colloidalsize particles dispersed in an aqueous solution of ions and small molecules. The action of soaps and detergents occurs by the formation of an emulsion, a liquid (soap dissolved in grease) dispersed in another liquid (water).

| Table 13.7 | Types of Colloids |  |  |
| :--- | :--- | :--- | :--- |
| Colloid Type | Dispersed <br> Substance | Dispersing <br> Medium | Example(s) |
| Aerosol | Liquid | Gas | Fog |
| Aerosol | Solid | Gas | Smoke |
| Foam | Gas | Liquid | Whipped cream |
| Solid foam | Gas | Solid | Marshmallow |
| Emulsion | Liquid | Liquid | Milk |
| Solid emulsion | Liquid | Solid | Butter |
| Sol | Solid | Liquid | Paint, cell fluid |
| Solid sol | Solid | Solid | Opal |

"Soaps" in Your Small Intestine In the small intestine, fats are digested by bile salts, which are soaplike molecules with smaller polar-ionic and larger nonpolar portions. Secreted by the liver, stored in the gallbladder, and released in the intestine, bile salts emulsify fats just as soap emulsifies grease: Fatty aggregates are broken down into particles of colloidal size and dispersed in the watery fluid. The fats are then broken down further and transported into the blood for cellular metabolism.

B
Figure 13.32 Light scattering and the Tyndall effect. A, When a beam of light passes through a solution (left jar), its path remains narrow and barely visible. When it passes through a colloid (right jar), it is scattered and broadened by the particles and thus easily visible. B, Sunlight is scattered as it shines through misty air in a forest.

Most colloids are cloudy or opaque, but some are transparent to the naked eye. When light passes through a colloid, it is scattered randomly by the dispersed particles because their sizes are similar to the wavelengths of visible light (400 to 750 nm ). Viewed from the side, the scattered light beam is visibly broader than one passing through a solution. This light-scattering phenomenon is called the Tyndall effect (Figure 13.32). Dust in air displays this effect when sunlight shines through it, as does mist pierced by headlights at night.

Under low magnification, you can see colloidal particles exhibit Brownian motion, a characteristic movement in which the particles change speed and direction erratically. This motion results because the colloidal particles are being pushed this way and that by molecules of the dispersing medium. These collisions are primarily responsible for keeping colloidal particles from settling out. (Einstein's explanation of Brownian motion in 1905 was a principal factor in the acceptance of the molecular nature of matter.)

When colloidal particles collide, why don't they aggregate into larger particles and settle out? Interparticle forces provide the explanation. Water-dispersed colloidal particles remain dispersed because they have charged surfaces that interact strongly with the water molecules through ion-dipole forces. Soap molecules form spherical micelles, with the charged heads forming the micelle exterior and the nonpolar tails interacting via dispersion forces in the interior. Aqueous proteins are typically spherical and mimic this micellar arrangement, with charged amino acid groups facing the water and uncharged groups buried within the molecule. Nonpolar oily particles can be dispersed in water by introducing ions, which are adsorbed onto their surfaces by dispersion forces. Charge repulsions between the adsorbed ions prevent the particles from aggregating.

Despite these forces, various methods can coagulate the particles and "destroy" the colloid. Heating a colloid makes the particles move faster and col-
 tle out. Adding an electrolyte solution introduces oppositely charged ions that neutralize the particles' surface charges, which allows the particles to coagulate and settle. Uncharged colloidal particles in smokestack gases are removed by creating ions that become adsorbed on the particles, which are then attracted to the charged plates of a Cottrell precipitator. Such precipitators are installed in the smokestacks of coal-burning power plants (Figure 13.33) and collect about $90 \%$ of colloidal smoke particulates, thus preventing their release into the air.

The upcoming Chemical Connections essay applies solution and colloid chemistry to the purification of water for residential and industrial use.

# Chemical Connections to Environmental Engineering Solutions and Colloids in Water Purification 

After decades of pollution and waste, we've finally begun to treasure clean water as a priceless, limited resource. Most water destined for human use comes from lakes, rivers, reservoirs, or groundwater sources that may also serve as the final sink after the water is used. Dissolved organic compounds, some of which are toxic, may be present, as well as high concentrations of mineral ions, such as $\mathrm{NO}_{3}{ }^{-}$and $\mathrm{Fe}^{3+}$. Clay and microbes are dispersed as colloids, and larger particles and debris are present in suspension. Water must be treated to remove these dissolved, dispersed, and suspended particles to make it clean enough to drink.

## Water Treatment Plants

Treating water for human use involves these steps (Figure B13.1):
Step 1. Screening and settling. As water moves into a treatment facility, screens remove large debris and then gravitational settling removes small, denser particles, such as sand.

Step 2. Coagulating. A series of processes must then remove microorganisms and other colloids. These particles typically have negatively charged surfaces, so they repel each other. Coagulating of colloids occurs by adding aluminum sulfate [cake alum; $\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}$ ] or iron(III) chloride $\left(\mathrm{FeCl}_{3}\right)$, which supply triply charged cations $\mathrm{Al}^{3+}$ or $\mathrm{Fe}^{3+}$ to neutralize the surface charges and allow the particles to aggregate through van der Waals forces.

Step 3. Flocculating and sedimenting. In these processes, the water and flocculating agents are carefully mixed in large basins using paddles, which causes a fluffy floc to form. Specific cationic polymers added at this point serve as long-chain bridges betyeen floc particles, which then grow bigger and heavier. These particles flow into other basins where they settle out and are removed. Instead of sedimentation, some plants use dissolved air flotation (DAF), in which fine air bubbles forced up through the water attach to the floc, and the floating mass is then skimmed.

Step 4. Filtering. Several types of filters are used to remove remaining colloidal particles. In slow sand filters, the water passes through a bed of sand and/or gravel of increasing particle size. In rapid sand filters, the sand is backwashed by passing water up though it, and the colloidal mass is removed. Membrane filters (not shown in Figure B13.1) with pore sizes of $0.1-10 \mu \mathrm{~m}$ occur as thin tubes bundled together inside a vessel. The water is forced into the tubes and the colloid-free filtrate is collected from a large central core tube. Filtration is very effective at removing microorganisms that are resistant to disinfection.

Step 5. Disinfecting. Nearly all water sources contain harmful microorganisms, and these are killed by one of three disinfecting agents. Chlorine, either as a bleach solution $\left(\mathrm{ClO}^{-}\right)$or as $\mathrm{Cl}_{2}$ gas, is the most common. But chlorine reacts with dissolved organic compounds to form chlorinated compounds, some of which are carcinogenic. Another agent is UV light emitted by specialized high-intensity fluorescent tubes. It disinfects by disrupting bonds in microorganisms' DNA. A third common disinfectant is ozone $\left(\mathrm{O}_{3}\right)$ gas, a powerful oxidizing agent. Often a small amount of $\mathrm{Cl}_{2}$ is added after UV or $\mathrm{O}_{3}$ treatment to prevent contamination in the storage tank. Following disinfection, other compounds may be added, such as sodium fluoride ( NaF ) to prevent tooth decay and phosphate salts to prevent leaching of lead from pipes.

Step 6. Adsorbing onto granular activated carbon (GAC). A common final step in water treatment is the removal of petroleum and other dissolved organic contaminants by adsorption onto GGAC. This highly porous material is formed by "activating" wood, coal, or coconut shells through treatment with steam: 1 kg of GAC has a surface area of about 275 acres! When all the active sites are filled, the GAC is discarded or regenerated with steam.
(continued)

Figure B13.1 The steps in a typical municipal wastewater treatment plant. Before water is sent to users, (1) it is screened to remove large debris, (2) coagulants are added to destabilize colloidal particles, (3) flocculation (slow mixing) is used to cause the particles to aggregate
and form fluffy floc, which is removed by sedimentation, (4) filtration is used to remove remaining floc and microorganisms, and (5) chlorine, UV light, or ozone is used to destroy any remaining microorganisms.

## Water Softening via Ion Exchange

Water that contains large amounts of doubly charged cations, such as $\mathrm{Ca}^{2+}$ and $\mathrm{Mg}^{2+}$, is called hard water. During cleaning, the cations combine with the fatty-acid anions in soap to produce insoluble deposits on clothes, washing machine parts, and sinks:

$$
\begin{gathered}
\mathrm{Ca}^{2+}(a q)+2 \mathrm{C}_{17} \mathrm{H}_{35} \mathrm{COONa}(a q) \longrightarrow \\
\text { soap } \quad\left(\mathrm{C}_{17} \mathrm{H}_{35} \mathrm{COO}\right)_{2} \mathrm{Ca}(s)+2 \mathrm{Na}^{+}(a q) \\
\text { insoluble deposit }
\end{gathered}
$$

When a large amount of $\mathrm{HCO}_{3}{ }^{-}$is present, the hard-water cations form scale, insoluble carbonate deposits in boilers and hot-water pipes that interfere with the transfer of heat and damage plumbing: $\mathrm{Ca}^{2+}(a q)+2 \mathrm{HCO}_{3}^{-}(a q) \longrightarrow \mathrm{CaCO}_{3}(s)+\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)$
The removal of hard-water cations, called water softening, is accomplished by exchanging $\mathrm{Na}^{+}$ions for $\mathrm{Ca}^{2+}$ and $\mathrm{Mg}^{2+}$ ions. A typical domestic system for ion exchange contains an ionexchange resin, an insoluble polymer that has covalently bonded anion groups, such as $-\mathrm{SO}_{3}{ }^{-}$or $-\mathrm{COO}^{-}$, to which $\mathrm{Na}^{+}$ions are attached to balance the charges (Figure B13.2). The divalent cations in hard water are attracted to the resin's anionic groups and displace the $\mathrm{Na}^{+}$ions into the water. When all the resin sites are occupied, the resin is "regenerated" with a concentrated $\mathrm{Na}^{+}$solution, which exchanges $\mathrm{Na}^{+}$ions for the bound $\mathrm{Ca}^{2+}$ and $\mathrm{Mg}^{2+}$.

## Membrane Processes and Reverse Osmosis

As we said on p. 541, membranes with pore sizes of $0.1-10 \mu \mathrm{~m}$ are used to filter colloids and microorganisms out of drinking water. In reverse osmosis, membranes with pores of $0.0001-0.01 \mu \mathrm{~m}$ are used to remove dissolved ions. Earlier in this chapter (p. 532), you saw how solutions of different concentrations separated by a semipermeable membrane give rise to an osmotic pressure. In reverse osmosis, a pressure greater than the osmotic pressure is applied to the concentrated solution, forcing the water back through the membrane and filtering out the ions. In domestic water systems, reverse osmosis is used to remove toxic heavy-metal ions, such as $\mathrm{Pb}^{2+}, \mathrm{Cd}^{2+}$, and $\mathrm{Hg}^{2+}$, present at concentrations too low for removal by ion exchange. On a much larger scale, reverse osmosis is used in the process of desalination, which removes large amounts of ions from seawater (Figure B13.3). Seawater containing about $40,000 \mathrm{ppm}$ of dissolved salts can be converted to a solution of about 400 ppm , which is suitable for drinking.

## Wastewater Treatment

Used water, or wastewater, must be treated before being returned to the groundwater, river, or lake. Industrial wastewater may also contain toxic components. In primary wastewater treatment, the water enters a settling basin to remove denser particles. Most municipalities also include biological wastewater treatment in which bacteria metabolize organic compounds in the wastewater and are then removed by settling. If needed, biological treatment is supplemented by advanced wastewater treatment tailored to a specific pollutant. For example, ammonia in wastewater causes excessive growth of plants and algae in surface water. It can be removed throtghatno-steprocess. In a nitrification step, specific aerobic bacteria use ammonia as a reducing agent (electron donor) and oxygen as an oxidizing agent (electron acceptor):

$$
\mathrm{NH}_{4}^{+}+2 \mathrm{O}_{2} \longrightarrow \mathrm{NO}_{3}^{-}+2 \mathrm{H}^{+}+\mathrm{H}_{2} \mathrm{O}
$$

Then, in a denitrification step, an organic compound such as methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ is added, and other bacteria oxidize it using the $\mathrm{NO}_{3}{ }^{-}$formed in the nitrification step:

$$
5 \mathrm{CH}_{3} \mathrm{OH}+6 \mathrm{NO}_{3}^{-} \longrightarrow 3 \mathrm{~N}_{2}+5 \mathrm{CO}_{2}+7 \mathrm{H}_{2} \mathrm{O}+6 \mathrm{OH}^{-}
$$

Thus, the overall process converts $\mathrm{NH}_{3}$ in wastewater to harmless $\mathrm{N}_{2}$ gas, which is released to the atmosphere.

Figure B13.3 Reverse osmosis for the removal of ions. A, A section of a coiled reverse-osmosis permeator. B, Each permeator contains a bundle of thin, hollow fibers of semipermeable membrane. C, Seawater is pumped through the permeator at high pressure. Most of the ions are removed, so much purer water enters the fibers and is collected.

## Section Summary

Colloidal particles are smaller than those in a suspension and larger than those in a solution. - Colloids are classified by the physical states of the dispersed and dispersing substances and are formed from many combinations of gas, liquid, and solid. - Colloids have extremely large surface areas, scatter incoming light (Tyndall effect), and exhibit random (Brownian) motion. - Colloidal particles in water have charged surfaces that keep them dispersed, but they can be coagulated by heating or by the addition of ions.

## Chapter Perspective

In Chapter 12, you saw how pure liquids and solids behave, and here you've seen how their behaviors change when they are mixed together. Two features of these systems reappear in later chapters: their equilibrium nature in Chapters 17 to 19 and the importance of entropy in Chapter 20.

This chapter completes our general discussion of atomic and molecular properties and their influence on the properties of matter. Immediately following is an Interchapter feature that reviews these properties in a pictorial format and helps preview their application in the next two chapters. In Chapter 14, we travel through the main groups of the periodic table, applying the ideas you've learned so far to the chemical and physical behavior of the elements. Then, in Chapter 15, we apply them to carbon and its nearest neighbors to see how their properties are responsible for the fascinating world of organic substances, including synthetic polymers and biomolecules.

From Colloid to Civilization At times, civilizations have been born where colloids were being coagulated by electrolyte solutions. At the mouths of rivers, where salt concentrations increase near an ocean or sea, the clay particles dispersed in the river water come together to form muddy deltas, such as those of the Nile (reddish area in photo) and the Mississippi. The ancient Egyptian empire and the city of New Orleans are the results of this global colloid chemistry.

CHAPTER REVIEW GUIDE
The following sections provide many aids to help you study this chapter. (Numbers in parentheses refer to pages, unless noted otherwise.)

## Learning Objectives These are concepts and skills you should know after studying this chapter.

Relevant section and/or sample problem (SP) numbers appear in parentheses.

## Understand These Concepts

1. The quantitative meaning of solubility (13.1)
2. The major types of intermolecular forces in solution and their relative strengths (13.1)
3. How the like-dissolves-like rule depends on intermolecular forces (13.1)
4. Why gases have relatively low solubilities in water (13.1)
5. General characteristics of solutions formed by various combinations of gases, liquids, and solids (13.1)
6. How intermolecular forces stabilize the structures of proteins, the cell membrane, DNA, and cellulose (13.2)
7. The enthalpy components of a solution cycle and their effect on $\Delta H_{\text {soln }}(13.3)$
8. The dependence of $\Delta H_{\text {hydr }}$ on ionic charge density and the factors that determine whether ionic solution processes are exothermic or endothermic (13.3)
9. The meaning of entropy and how the balance between the change in enthalpy and the change in entropy governs the solution process (13.3)
10. The distinctions among saturated, unsaturated, and supersaturated solutions, and the equilibrium nature of a saturated solution (13.4)
11. The relation between temperature and the solubility of solids (13.4)
12. Why the solubility of gases in water decreases with a rise in temperature (13.4)
13. The effect of gas pressure on solubility and its quantitative expression as Henry's law (13.4)
14. The meaning of molarity, molality, mole fraction, and parts by mass or by volume of a solution, and how to convert among them (13.5)
15. The distinction between electrolytes and nonelectrolytes in solution (13.6)
16. The four colligative properties and their dependence on number of dissolved particles (13.6)
17. Ideal solutions and the importance of Raoult's law (13.6)
18. How the phase diagram of a solution differs from that of the pure solvent (13.6)
19. Why the vapor over a solution of volatile nonelectrolyte is richer in the more volatile component (13.6)
20. Why electrolyte solutions are not ideal and the meanings of the van't Hoff factor and ionic atmosphere (13.6)
21. How particle size distinguishes suspensions, colloids, and solutions (13.7)
22. How colloidal behavior is demonstrated by the Tyndall effect and Brownian motion (13.7)

## Learning Objectives (continued)

## Master These Skills

1. Predicting relative solubilities from intermolecular forces (SP 13.1)
2. Using Henry's law to calculate the solubility of a gas (SP 13.2)
3. Expressing concentration in terms of molality, parts by mass, parts by volume, and mole fraction (SPs 13.3, 13.4)
4. Interconverting among the various terms for expressing concentration (SP 13.5)
5. Using Raoult's law to calculate the vapor pressure lowering of a solution (SP 13.6)
6. Determining boiling point elevation and freezing point depression of a solution (SP 13.7)
7. Using a colligative property to calculate the molar mass of a solute (SP 13.8)
8. Calculating the composition of vapor over a solution of volatile nonelectrolyte (13.6)
9. Calculating the van't Hoff factor $i$ from the magnitude of a colligative property (13.6)
10. Using a solution depiction to determine colligative properties (SP 13.9)

Key Terms These important terms appear in boldface in the chapter and are defined again in the Glossary.

## Key Equations and Relationships Numbered and screened concepts are listed for you to refer to or memorize.

13.1 Dividing the general heat of solution into component enthalpies (515):

$$
\Delta H_{\text {soln }}=\Delta H_{\text {solute }}+\Delta H_{\text {solvent }}+\Delta H_{\text {mix }}
$$

13.2 Dividing the heat of solution of an ionic compound in water into component enthalpies (516):

$$
\Delta H_{\text {soln }}=\Delta H_{\text {lattice }}+\Delta H_{\text {hydr of the ions }}
$$

13.3 Relating gas solubility to its partial pressure (Henry's law) (522):

$$
S_{\mathrm{gas}}=k_{\mathrm{H}} \times P_{\mathrm{gas}}
$$

13.4 Defining concentration in terms of molarity (522):

$$
\text { Molarity }(M)=\frac{\text { amount }(\mathrm{mol}) \text { of solute }}{\text { volume }(\mathrm{L}) \text { of solution }}
$$

13.5 Defining concentration in terms of molality (523):

$$
\text { Molality }(m)=\frac{\text { amount }(\mathrm{mol}) \text { of solute }}{\operatorname{mass}(\mathrm{kg}) \text { of solvent }}
$$

13.6 Defining concentration in terms of mass percent (524):

Mass percent $[\%(\mathrm{w} / \mathrm{w})]=\frac{\text { mass of solute }}{\text { mass of solution }} \times 100$
13.7 Defining concentration in terms of volume percent (524):

Volume percent $[\%(\mathrm{v} / \mathrm{v})]=\frac{\text { volume of solute }}{\text { volume of solution }} \times 100$
13.8 Defining concentration in terms of mole fraction (525):

Mole fraction ( $X$ )

$$
=\frac{\text { amount }(\mathrm{mol}) \text { of solute }}{\text { amount }(\mathrm{mol}) \text { of solute }+\operatorname{amount}(\mathrm{mol}) \text { of solvent }}
$$

13.9 Expressing the relationship between the vapor pressure of solvent above a solution and its mole fraction in the solution (Raoult's law) (528):

$$
P_{\text {solvent }}=X_{\text {solvent }} \times P_{\text {solvent }}^{\circ}
$$

13.10 Calculating the vapor pressure lowering due to solute (529):

$$
\Delta P=X_{\text {solute }} \times P_{\text {solvent }}^{\circ}
$$

13.11 Calculating the boiling point elevation of a solution (530):

$$
\Delta T_{\mathrm{b}}=K_{\mathrm{b}} m
$$

13.12 Calculating the freezing point depression of a solution (531):

$$
\Delta T_{\mathrm{f}}=K_{\mathrm{f}} m
$$

13.13 Calculating the osmotic pressure of a solution (532):

$$
\Pi=\frac{n_{\text {solute }}}{V_{\text {soln }}} R T=M R T
$$

Highlighted Figures and Tables These figures ( $F$ ) and tables ( $T$ ) provide a visual review of key ideas.

F13.1 Major types of intermolecular forces in solutions (502)
F13.2 Hydration shells around an aqueous ion (503)

## PROBLEMS

Problems with colored numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and provide the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

## Types of Solutions: Intermolecular Forces and Solubility

(Sample Problem 13.1)

## - Concept Review Questions

13.1 Describe how properties of seawater illustrate the two characteristics that define mixtures.
13.2 What types of intermolecular forces give rise to hydration shells in an aqueous solution of sodium chloride?
13.3 Acetic acid is miscible with water. Would you expect carboxylic acids with general formula $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{n} \mathrm{COOH}$ to become more or less water soluble as $n$ increases? Explain.
13.4 Which would you expect to be more effective as a soap, sodium acetate or sodium stearate? Explain.
13.5 Hexane and methanol are miscible as gases but only slightly soluble in each other as liquids. Explain.
13.6 Hydrogen chloride ( HCl ) gas is much more soluble than propane gas $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$ in water, even though HGl has a lower boild D ing point. Explain.

## Skill-Building Exercises (grouped in similar pairs)

13.7 Which gives the more concentrated solution, (a) $\mathrm{KNO}_{3}$ in $\mathrm{H}_{2} \mathrm{O}$ or (b) $\mathrm{KNO}_{3}$ in carbon tetrachloride $\left(\mathrm{CCl}_{4}\right)$ ? Explain.
13.8 Which gives the more concentrated solution, stearic acid [ $\left.\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{16} \mathrm{COOH}\right]$ in (a) $\mathrm{H}_{2} \mathrm{O}$ or (b) $\mathrm{CCl}_{4}$ ? Explain.
13.9 What is the strongest type of intermolecular force between solute and solvent in each solution?
(a) $\mathrm{CsCl}(s)$ in $\mathrm{H}_{2} \mathrm{O}(l)$
(b)

(c) $\mathrm{CH}_{3} \mathrm{OH}(l)$ in $\mathrm{CCl}_{4}(l)$
13.10 What is the strongest type of intermolecular force between solute and solvent in each solution?
(a) $\mathrm{Cu}(s)$ in $\mathrm{Ag}(s)$
(b) $\mathrm{CH}_{3} \mathrm{Cl}(\mathrm{g})$ in $\mathrm{CH}_{3} \mathrm{OCH}_{3}(g)$
(c) $\mathrm{CH}_{3} \mathrm{CH}_{3}(g)$ in $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}(l)$
13.11 What is the strongest type of intermolecular force between solute and solvent in each solution?
(a) $\mathrm{CH}_{3} \mathrm{OCH}_{3}(g)$ in $\mathrm{H}_{2} \mathrm{O}(l)$
(b) $\mathrm{Ne}(g)$ in $\mathrm{H}_{2} \mathrm{O}(l)$
(c) $\mathrm{N}_{2}(g)$ in $\mathrm{C}_{4} \mathrm{H}_{10}(g)$
13.12 What is the strongest type of intermolecular force between solute and solvent in each solution?
(a) $\mathrm{C}_{6} \mathrm{H}_{14}(l)$ in $\mathrm{C}_{8} \mathrm{H}_{18}(l)$
(b) $\mathrm{H}_{2} \mathrm{C}=\mathrm{O}(g)$ in $\mathrm{CH}_{3} \mathrm{OH}(l)$
(c) $\mathrm{Br}_{2}(l)$ in $\mathrm{CCl}_{4}(l)$
13.13 Which member of each pair is more soluble in diethyl ether? Why?
(a) $\mathrm{NaCl}(s)$ or $\mathrm{HCl}(g)$
(b) $\mathrm{H}_{2} \mathrm{O}(l)$ or $\mathrm{CH}_{3} \mathrm{CH}(l)$
(c) $\mathrm{MgBr}_{2}(s)$ or $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{MgBr}(s)$
13.14 Which member of each pair is more soluble in water? Why?
(a) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OCH}_{2} \mathrm{CH}_{3}(l)$ or $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OCH}_{3}(g)$
(b) $\mathrm{CH}_{2} \mathrm{Cl}_{2}(l)$ or $\mathrm{CCl}_{4}(l)$
(c)

tetrahydropyran
cyclohexane

## Problems in Context

13.15 The dictionary defines homogeneous as "uniform in composition throughout." River water is a mixture of dissolved compounds, such as calcium bicarbonate, and suspended soil particles. Is river water homogeneous? Explain.
13.16 Gluconic acid is a derivative of glucose used in cleaners and in the dairy and brewing industries. Caproic acid is a carboxylic acid used in the flavoring industry. Although both are six-carbon acids (see structures below), gluconic acid is soluble in water and nearly insoluble in hexane, whereas caproic acid has the opposite solubility behavior. Explain.

gluconic acid

$$
\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{COOH}
$$

## Fnhancer

caproic acid

## Intermolecular Forces and Biological Macromolecules

## - Concept Review Questions

13.17 Name three intermolecular forces that stabilize the shape of a soluble, globular protein, and explain how they act.
13.18 Name three intermolecular forces that stabilize the shape of DNA, and explain how they act.
13.19 Is the sodium salt of propanoic acid as effective a soap as sodium stearate? Explain.
13.20 What intermolecular forces stabilize a lipid bilayer?
13.21 In what way do proteins embedded in a membrane differ structurally from soluble proteins?
13.22 How can wood be so strong if it consists of cellulose chains held together by relatively weak H bonds?
13.23 Histones are proteins that control gene function by attaching through salt links to exterior regions of DNA. Name an amino acid whose side chain is often found on the exterior of histones.

## Why Substances Dissolve: Understanding the Solution Process

## - Concept Review Questions

13.24 What is the relationship between solvation and hydration? 13.25 For a general solvent, which enthalpy terms in the thermochemical solution cycle are combined to obtain $\Delta H_{\text {solvation }}$ ?
13.26 (a) What is the charge density of an ion, and what two properties of an ion affect it?
(b) Arrange the following in order of increasing charge density:

(c) How do the two properties in part (a) affect the ionic heat of hydration, $\Delta H_{\mathrm{hydr}}$ ?
13.27 For $\Delta H_{\text {soln }}$ to be very small, what quantities must be nearly equal in magnitude? Will their signs be the same or opposite?
13.28 Water is added to a flask containing solid $\mathrm{NH}_{4} \mathrm{Cl}$. As the salt dissolves, the solution becomes colder.
(a) Is the dissolving of $\mathrm{NH}_{4} \mathrm{Cl}$ exothermic or endothermic?
(b) Is the magnitude of $\Delta H_{\text {lattice }}$ of $\mathrm{NH}_{4} \mathrm{Cl}$ larger or smaller than the combined $\Delta H_{\mathrm{hydr}}$ of the ions? Explain.
(c) Given the answer to (a), why does $\mathrm{NH}_{4} \mathrm{Cl}$ dissolve in water? 13.29 An ionic compound has a highly negative $\Delta H_{\text {soln }}$ in water. Would you expect it to be very soluble or nearly insoluble in water? Explain in terms of enthalpy and entropy changes.

## - Skill-Building Exercises (grouped in similar pairs)

13.30 Sketch a qualitative enthalpy diagram for the process of dissolving $\mathrm{KCl}(s)$ in $\mathrm{H}_{2} \mathrm{O}$ (endothermic).
13.31 Sketch a qualitative enthalpy diagram for the process of dissolving $\mathrm{NaI}(s)$ in $\mathrm{H}_{2} \mathrm{O}$ (exothermic).
13.32 Which ion in each pair has greater charge density? Explain.
(a) $\mathrm{Na}^{+}$or $\mathrm{Cs}^{+}$
(b) $\mathrm{Sr}^{2+}$ or $\mathrm{Rb}^{+}$
(c) $\mathrm{Na}^{+}$or $\mathrm{Cl}^{-}$
(d) $\mathrm{O}^{2-}$ or $\mathrm{F}^{-}$
(e) $\mathrm{OH}^{-}$or $\mathrm{SH}^{-}$
(f) $\mathrm{Mg}^{2+}$ or $\mathrm{Ba}^{2+}$
(g) $\mathrm{Mg}^{2+}$ or $\mathrm{Na}^{+}$
(h) $\mathrm{NO}_{3}{ }^{-}$or $\mathrm{CO}_{3}{ }^{2-}$
13.33 Which ion has the lower ratio of charge to volume? Explain.
(a) $\mathrm{Br}^{-}$or $\mathrm{I}^{-}$
(b) $\mathrm{Sc}^{3+}$ or $\mathrm{Ca}^{2+}$
(c) $\mathrm{Br}^{-}$or $\mathrm{K}^{+}$
(d) $\mathrm{S}^{2-}$ or $\mathrm{Cl}^{-}$
(e) $\mathrm{Sc}^{3+}$ or $\mathrm{Al}^{3+}$
(f) $\mathrm{SO}_{4}{ }^{2-}$ or $\mathrm{ClO}_{4}{ }^{-}$
(g) $\mathrm{Fe}^{3+}$ or $\mathrm{Fe}^{2+}$
(h) $\mathrm{Ca}^{2+}$ or $\mathrm{K}^{+}$
13.34 Which has the larger $\Delta H_{\text {hydr }}$ in each pair of Problem 13.32? 13.35 Which has the smaller $\Delta H_{\text {hydr }}$ in each pair of Problem 13.33 13.36 (a) Use the following data to calculate the combined heat of hydration for the ions in potassium bromate $\left(\mathrm{KBrO}_{3}\right)$ :

$$
\Delta H_{\text {lattice }}=745 \mathrm{~kJ} / \mathrm{mol} \quad \Delta H_{\text {soln }}=41.1 \mathrm{~kJ} / \mathrm{mol}
$$

(b) Which ion contributes more to the answer to part (a)? Why? 13.37 (a) Use the following data to calculate the combined heat of hydration for the ions in sodium acetate $\left(\mathrm{NaC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)$ :

$$
\Delta H_{\text {lattice }}=763 \mathrm{~kJ} / \mathrm{mol} \quad \Delta H_{\text {soln }}=17.3 \mathrm{~kJ} / \mathrm{mol}
$$

(b) Which ion contributes more to the answer to part (a)? Why?
13.38 State whether the entropy of the system increases or decreases in each of the following processes:
(a) Gasoline burns in a car engine.
(b) Gold is extracted and purified from its ore.
(c) Ethanol $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\right)$ dissolves in 1-propanol
$\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}\right)$.
13.39 State whether the entropy of the system increases or decreases in each of the following processes:
(a) Pure gases are mixed to prepare an anesthetic.
(b) Electronic-grade silicon is prepared from sand.
(c) Dry ice (solid $\mathrm{CO}_{2}$ ) sublimes.

## Problems in Context

13.40 Besides its use in making black-and-white film, silver nitrate $\left(\mathrm{AgNO}_{3}\right)$ is used similarly in forensic science. The NaCl left behind in the sweat of a fingerprint is treated with $\mathrm{AgNO}_{3}$ solution to form AgCl . This precipitate is developed to show the black-and-white fingerprint pattern. Given $\Delta H_{\text {lattice }}$ of $\mathrm{AgNO}_{3}=822 \mathrm{~kJ} / \mathrm{mol}$ and $\Delta H_{\text {hydr }}=-799 \mathrm{~kJ} / \mathrm{mol}$, calculate its $\Delta H_{\text {soln }}$.

## Solubility as an Equilibrium Process

(Sample Problem 13.2)

## - Concept Review Questions

13.41 You are given a bottle of solid X and three aqueous solutions of X -one saturated, one unsaturated, and one supersaturated. How would you determine which solution is which?
13.42 Potassium permanganate $\left(\mathrm{KMnO}_{4}\right)$ has a solubility of $6.4 \mathrm{~g} / 100 \mathrm{~g}$ of $\mathrm{H}_{2} \mathrm{O}$ at $20^{\circ} \mathrm{C}$ and a curve of solubility vs. temperature that slopes upward to the right. How would you prepare a supersaturated solution of $\mathrm{KMnO}_{4}$ ?
13.43 Why does the solubility of any gas in water decrease with rising temperature?

- Skill-Building Exercises (grouped in similar pairs)
13.44 For a saturated aqueous solution of each of the following at $20^{\circ} \mathrm{C}$ and 1 atm , will the solubility increase, decrease, or stay the same when the indicated change occurs?
(a) $\mathrm{O}_{2}(g)$, increase $P$
(b) $\mathrm{N}_{2}(g)$, increase $V$
13.45 For a saturated aqueous solution of each of the following at $20^{\circ} \mathrm{C}$ and 1 atm , will the solubility increase, decrease, or stay the same when the indicated change occurs?
(a) $\mathrm{He}(g)$, decrease $T$
(b) $\operatorname{RbI}(s)$, increase $P$
13.46 The Henry's law constant $\left(k_{\mathrm{H}}\right)$ for $\mathrm{O}_{2}$ in water at $20^{\circ} \mathrm{C}$ is $1.28 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$. (a) How many grams of $\mathrm{O}_{2}$ will dissolve in 2.50 L of $\mathrm{H}_{2} \mathrm{O}$ that is in contact with pure $\mathrm{O}_{2}$ at 1.00 atm ? (b) How many grams of $\mathrm{O}_{2}$ will dissolve in 2.50 L of $\mathrm{H}_{2} \mathrm{O}$ that is in contact with air, where the partial pressure of $\mathrm{O}_{2}$ is 0.209 atm ? 13.47 Argon makes up $0.93 \%$ by volume of air. Calculate its solubility ( $\mathrm{mol} / \mathrm{L}$ ) in water at $20^{\circ} \mathrm{C}$ and 1.0 atm . The Henry's law Enconstantoreuthder these conditions is $1.5 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$.

## Problems in Context

13.48 Caffeine is about 10 times as soluble in hot water as in cold water. A chemist puts a hot-water extract of caffeine into an ice bath, and some caffeine crystallizes. Is the remaining solution saturated, unsaturated, or supersaturated?
13.49 The partial pressure of $\mathrm{CO}_{2}$ gas above the liquid in a bottle of champagne at $20^{\circ} \mathrm{C}$ is 5.5 atm . What is the solubility of $\mathrm{CO}_{2}$ in champagne? Assume Henry's law constant is the same for champagne as for water: at $20^{\circ} \mathrm{C}, k_{\mathrm{H}}=3.7 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$.
13.50 Respiratory problems are treated with devices that deliver air with a higher partial pressure of $\mathrm{O}_{2}$ than normal air. Why?

## Quantitative Ways of Expressing Concentration (Sample Problems 13.3 to 13.5)

## Concept Review Questions

13.51 Explain the difference between molarity and molality. Under what circumstances would molality be a more accurate measure of the concentration of a prepared solution than molarity? Why?
13.52 Which way of expressing concentration includes (a) volume of solution; (b) mass of solution; (c) mass of solvent?
13.53 A solute has a solubility in water of $21 \mathrm{~g} / \mathrm{kg}$ solvent. Is this value the same as $21 \mathrm{~g} / \mathrm{kg}$ solution? Explain.
13.54 You want to convert among molarity, molality, and mole fraction of a solution. You know the masses of solute and solvent and the volume of solution. Is this enough information to carry out all the conversions? Explain.
13.55 When a solution is heated, which ways of expressing concentration change in value? Which remain unchanged? Explain.

Skill-Building Exercises (grouped in similar pairs)
13.56 Calculate the molarity of each aqueous solution:
(a) 32.3 g of table sugar $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$ in $100 . \mathrm{mL}$ of solution
(b) 5.80 g of $\mathrm{LiNO}_{3}$ in 505 mL of solution
13.57 Calculate the molarity of each aqueous solution:
(a) 0.82 g of ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ in 10.5 mL of solution
(b) 1.27 g of gaseous $\mathrm{NH}_{3}$ in 33.5 mL of solution
13.58 Calculate the molarity of each aqueous solution:
(a) 78.0 mL of 0.240 M NaOH diluted to 0.250 L with water
(b) 38.5 mL of 1.2 M HNO 3 diluted to 0.130 L with water
13.59 Calculate the molarity of each aqueous solution:
(a) 25.5 mL of 6.25 M HCl diluted to 0.500 L with water
(b) 8.25 mL of $2.00 \times 10^{-2} \mathrm{M}$ KI diluted to 12.0 mL with water
13.60 How would you prepare the following aqueous solutions?
(a) 365 mL of $8.55 \times 10^{-2} M \mathrm{KH}_{2} \mathrm{PO}_{4}$ from solid $\mathrm{KH}_{2} \mathrm{PO}_{4}$
(b) 465 mL of 0.335 M NaOH from 1.25 M NaOH
13.61 How would you prepare the following aqueous solutions?
(a) 2.5 L of 0.65 M NaCl from solid NaCl
(b) 15.5 L of 0.3 M urea $\left[\left(\mathrm{NH}_{2}\right)_{2} \mathrm{C}=\mathrm{O}\right]$ from 2.1 M urea
13.62 How would you prepare the following aqueous solutions?
(a) 1.40 L of 0.288 M KBr from solid KBr
(b) 255 mL of $0.0856 M \mathrm{LiNO}_{3}$ from $0.264 M \mathrm{LiNO}_{3}$
13.63 How would you prepare the following aqueous solutions?
(a) 57.5 mL of $1.53 \times 10^{-3} M \mathrm{Cr}\left(\mathrm{NO}_{3}\right)_{3}$ from solid $\mathrm{Cr}\left(\mathrm{NO}_{3}\right)_{3}$
(b) $5.8 \times 10^{3} \mathrm{~m}^{3}$ of $1.45 \mathrm{M} \mathrm{NH}_{4} \mathrm{NO}_{3}$ from $2.50 ~ M \mathrm{NH}_{4} \mathrm{NO}_{3}$
13.64 Calculate the molality of the following:
(a) A solution containing 85.4 g of glycine $\left(\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{COOH}\right)$ dissolved in 1.270 kg of $\mathrm{H}_{2} \mathrm{O}$
(b) A solution containing 8.59 g of glycerol $\mathrm{C}_{3} \mathrm{Hf}_{8}^{8} \Theta_{3}^{9}$ ip $77 . \mathrm{P}_{\mathrm{g}}$ of ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$
13.65 Calculate the molality of the following:
(a) A solution containing 174 g of HCl in 757 g of $\mathrm{H}_{2} \mathrm{O}$
(b) A solution containing 16.5 g of naphthalene $\left(\mathrm{C}_{10} \mathrm{H}_{8}\right)$ in 53.3 g of benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$
13.66 What is the molality of a solution consisting of 44.0 mL of benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6} ; d=0.877 \mathrm{~g} / \mathrm{mL}\right)$ in 167 mL of hexane $\left(\mathrm{C}_{6} \mathrm{H}_{14}\right.$; $d=0.660 \mathrm{~g} / \mathrm{mL})$ ?
13.67 What is the molality of a solution consisting of 2.66 mL of carbon tetrachloride $\left(\mathrm{CCl}_{4} ; d=1.59 \mathrm{~g} / \mathrm{mL}\right)$ in 76.5 mL of methylene chloride $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2} ; d=1.33 \mathrm{~g} / \mathrm{mL}\right)$ ?
13.68 How would you prepare the following aqueous solutions?
(a) $3.10 \times 10^{2} \mathrm{~g}$ of 0.125 m ethylene glycol $\left(\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}\right)$ from ethylene glycol and water
(b) 1.20 kg of 2.20 mass $\% \mathrm{HNO}_{3}$ from 52.0 mass $\% \mathrm{HNO}_{3}$
13.69 How would you prepare the following aqueous solutions?
(a) 1.50 kg of 0.0355 m ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ from ethanol and water
(b) 445 g of 13.0 mass $\% \mathrm{HCl}$ from 34.1 mass $\% \mathrm{HCl}$
13.70 A solution contains 0.35 mol of isopropanol $\left(\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}\right)$ dissolved in 0.85 mol of water. (a) What is the mole fraction of isopropanol? (b) The mass percent? (c) The molality?
13.71 A solution contains 0.100 mol of NaCl dissolved in 8.60 mol of water. (a) What is the mole fraction of NaCl ? (b) The mass percent? (c) The molality?
13.72 What mass of cesium bromide must be added to 0.500 L of water $(d=1.00 \mathrm{~g} / \mathrm{mL})$ to produce a 0.400 m solution? What are the mole fraction and the mass percent of CsBr ?
13.73 What are the mole fraction and the mass percent of a solution made by dissolving 0.30 g of KI in 0.400 L of water $(d=1.00 \mathrm{~g} / \mathrm{mL})$ ?
13.74 Calculate the molality, molarity, and mole fraction of $\mathrm{NH}_{3}$ in an 8.00 mass $\%$ aqueous solution $(d=0.9651 \mathrm{~g} / \mathrm{mL})$.
13.75 Calculate the molality, molarity, and mole fraction of $\mathrm{FeCl}_{3}$ in a 28.8 mass \% aqueous solution ( $d=1.280 \mathrm{~g} / \mathrm{mL}$ ).

## Problems in Context

13.76 Wastewater from a cement factory contains 0.25 g of $\mathrm{Ca}^{2+}$ ion and 0.056 g of $\mathrm{Mg}^{2+}$ ion per 100.0 L of solution. The solution density is $1.001 \mathrm{~g} / \mathrm{mL}$. Calculate the $\mathrm{Ca}^{2+}$ and $\mathrm{Mg}^{2+}$ concentrations in ppm (by mass).
13.77 An automobile antifreeze mixture is made by mixing equal volumes of ethylene glycol ( $d=1.114 \mathrm{~g} / \mathrm{mL} ; \mathcal{M}=62.07 \mathrm{~g} / \mathrm{mol}$ ) and water $(d=1.00 \mathrm{~g} / \mathrm{mL})$ at $20^{\circ} \mathrm{C}$. The density of the mixture is $1.070 \mathrm{~g} / \mathrm{mL}$. Express the concentration of ethylene glycol as:
(a) Volume percent
(b) Mass percent
(d) Molality
(e) Mole fraction
(c) Molarity

## Colligative Properties of Solutions

(Sample Problems 13.6 to 13.9)

## - Concept Review Questions

13.78 The chemical formula of a solute does not affect the extent of the solution's colligative properties. What characteristic of a solute does affect these properties? Name a physical property of a solution that is affected by the chemical formula of the solute.
13.79 What is a nonvolatile nonelectrolyte? Why is this type of solute the simplest case for examining colligative properties?
 erty of the substance makes it a strong electrolyte?
13.81 Express Raoult's law in words. Is Raoult's law valid for a solution of a volatile solute? Explain.
13.82 What are the most important differences between the phase diagram of a pure solvent and the phase diagram of a solution of that solvent?
13.83 Is the composition of the vapor at the top of a fractionating column different from the composition at the bottom? Explain.
13.84 Is the boiling point of $0.01 \mathrm{~m} \mathrm{KF}(\mathrm{aq})$ higher or lower than that of 0.01 m glucose $(a q)$ ? Explain.
13.85 Which aqueous solution has a boiling point closer to its predicted value, 0.050 m NaF or 0.50 m KCl ? Explain.
13.86 Which aqueous solution has a freezing point closer to its predicted value, 0.01 m NaBr or $0.01 \mathrm{~m} \mathrm{MgCl}_{2}$ ? Explain.
13.87 The freezing point depression constants of the solvents cyclohexane and naphthalene are $20.1^{\circ} \mathrm{C} / \mathrm{m}$ and $6.94^{\circ} \mathrm{C} / \mathrm{m}$, respectively. Which solvent would give a more accurate result if you are using freezing point depression to determine the molar mass of a substance that is soluble in either one? Why?

## Skill-Building Exercises (grouped in similar pairs)

13.88 Classify the following substances as strong electrolytes, weak electrolytes, or nonelectrolytes:
(a) Hydrogen chloride $(\mathrm{HCl})$
(b) Potassium nitrate $\left(\mathrm{KNO}_{3}\right)$
(c) Glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$
(d) Ammonia $\left(\mathrm{NH}_{3}\right)$
13.89 Classify the following substances as strong electrolytes, weak electrolytes, or nonelectrolytes:
(a) Sodium permanganate $\left(\mathrm{NaMnO}_{4}\right)$
(b) Acetic acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$
(c) Methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ (d) Calcium acetate $\left[\mathrm{Ca}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{2}\right]$
13.90 How many moles of solute particles are present in 1 L of each of the following aqueous solutions?
(a) 0.3 M KBr
(b) $0.065 \mathrm{M} \mathrm{HNO}_{3}$
(c) $10^{-4} M \mathrm{KHSO}_{4}$
(d) 0.06 M ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$
13.91 How many moles of solute particles are present in 1 mL of each of the following aqueous solutions?
(a) $0.02 \mathrm{M} \mathrm{CuSO}_{4}$
(b) $0.004 \mathrm{M} \mathrm{Ba}(\mathrm{OH})_{2}$
(c) 0.08 M pyridine $\left(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\right)$
(d) $0.05 \mathrm{M}\left(\mathrm{NH}_{4}\right)_{2} \mathrm{CO}_{3}$
13.92 Which solution has the lower freezing point?
(a) 11.0 g of $\mathrm{CH}_{3} \mathrm{OH}$ in $100 . \mathrm{g}$ of $\mathrm{H}_{2} \mathrm{O}$ or
22.0 g of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ in 200. g of $\mathrm{H}_{2} \mathrm{O}$
(b) 20.0 g of $\mathrm{H}_{2} \mathrm{O}$ in 1.00 kg of $\mathrm{CH}_{3} \mathrm{OH}$ or
20.0 g of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ in 1.00 kg of $\mathrm{CH}_{3} \mathrm{OH}$
13.93 Which solution has the higher boiling point?
(a) 38.0 g of $\mathrm{C}_{3} \mathrm{H}_{8} \mathrm{O}_{3}$ in 250 g of ethanol or
38.0 g of $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}$ in 250 . g of ethanol
(b) 15 g of $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}$ in 0.50 kg of $\mathrm{H}_{2} \mathrm{O}$ or

15 g of NaCl in 0.50 kg of $\mathrm{H}_{2} \mathrm{O}$
13.94 Rank the following aqueous solutions in order of increasing (a) osmotic pressure; (b) boiling point; (c) freezing point;
(d) vapor pressure at $50^{\circ} \mathrm{C}$ :
(I) $0.100 \mathrm{~m} \mathrm{NaNO}_{3}$ (II) 0.100 m glucose (III) $0.100 \mathrm{~m} \mathrm{CaCl}_{2}$
13.95 Rank the following aqueous solutions in order of decreasing (a) osmotic pressure; (b) boiling point; (c) freezing point; (d) vapor pressure at 298 K :
(I) 0.04 m urea $\left[\left(\mathrm{NH}_{2}\right)_{2} \mathrm{C}=\mathrm{O}\right]$
(II) $0.01 \mathrm{~m} \mathrm{AgNO}_{3}$
(III) $0.03 \mathrm{~m} \mathrm{CuSO}_{4}$
13.96 Calculate the vapor pressure of a solution of 34.0 got Pyycerol $\left(\mathrm{C}_{3} \mathrm{H}_{8} \mathrm{O}_{3}\right)$ in 500.0 g of water at $25^{\circ} \mathrm{C}$. The vapor pressure of water at $25^{\circ} \mathrm{C}$ is 23.76 torr. (Assume ideal behavior.)
13.97 Calculate the vapor pressure of a solution of 0.39 mol of cholesterol in 5.4 mol of toluene at $32^{\circ} \mathrm{C}$. Pure toluene has a vapor pressure of 41 torr at $32^{\circ} \mathrm{C}$. (Assume ideal behavior.)
13.98 What is the freezing point of 0.251 m urea in water? 13.99 What is the boiling point of 0.200 m lactose in water?
13.100 The boiling point of ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ is $78.5^{\circ} \mathrm{C}$. What is the boiling point of a solution of 6.4 g of vanillin $\mathcal{M}=$ $152.14 \mathrm{~g} / \mathrm{mol})$ in 50.0 g of ethanol ( $K_{\mathrm{b}}$ of ethanol $\left.=1.22^{\circ} \mathrm{C} / \mathrm{m}\right)$ ?
13.101 The freezing point of benzene is $5.5^{\circ} \mathrm{C}$. What is the freezing point of a solution of 5.00 g of naphthalene $\left(\mathrm{C}_{10} \mathrm{H}_{8}\right)$ in 444 g of benzene ( $K_{\mathrm{f}}$ of benzene $=4.90^{\circ} \mathrm{C} / \mathrm{m}$ ) ?
13.102 What is the minimum mass of ethylene glycol $\left(\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}\right)$ that must be dissolved in 14.5 kg of water to prevent the solution from freezing at $-12.0^{\circ} \mathrm{F}$ ? (Assume ideal behavior.)
13.103 What is the minimum mass of glycerol $\left(\mathrm{C}_{3} \mathrm{H}_{8} \mathrm{O}_{3}\right)$ that must be dissolved in 11.0 mg of water to prevent the solution from freezing at $-15^{\circ} \mathrm{C}$ ? (Assume ideal behavior.)
13.104 Calculate the molality and van't Hoff factor $(i)$ for the following aqueous solutions:
(a) 1.00 mass $\% \mathrm{NaCl}$, freezing point $=-0.593^{\circ} \mathrm{C}$
(b) 0.500 mass $\% \mathrm{CH}_{3} \mathrm{COOH}$, freezing point $=-0.159^{\circ} \mathrm{C}$
13.105 Calculate the molality and van't Hoff factor $(i)$ for the following aqueous solutions:
(a) 0.500 mass $\% \mathrm{KCl}$, freezing point $=-0.234^{\circ} \mathrm{C}$
(b) 1.00 mass $\% \mathrm{H}_{2} \mathrm{SO}_{4}$, freezing point $=-0.423^{\circ} \mathrm{C}$

## Problems in Context

13.106 Wastewater discharged into a stream by a sugar refinery contains 3.55 g of sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$ per liter. A governmentindustry project is designed to test the feasibility of removing the sugar by reverse osmosis. What pressure must be applied to the apparatus at $20 .{ }^{\circ} \mathrm{C}$ to produce pure water?
13.107 In a study designed to prepare new gasoline-resistant coatings, a polymer chemist dissolves 6.053 g of poly(vinyl alcohol) in enough water to make 100.0 mL of solution. At $25^{\circ} \mathrm{C}$, the osmotic pressure of this solution is 0.272 atm . What is the molar mass of the polymer sample?
13.108 The U.S. Food and Drug Administration lists dichloromethane $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ and carbon tetrachloride $\left(\mathrm{CCl}_{4}\right)$ among the many cancer-causing chlorinated organic compounds. What are the partial pressures of these substances in the vapor above a solution of 1.60 mol of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and 1.10 mol of $\mathrm{CCl}_{4}$ at $23.5^{\circ} \mathrm{C}$ ? The vapor pressures of pure $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and $\mathrm{CCl}_{4}$ at $23.5^{\circ} \mathrm{C}$ are 352 torr and 118 torr, respectively. (Assume ideal behavior.)

## The Structure and Properties of Colloids

## Concept Review Questions

13.109 Is the fluid inside a bacterial cell considered a solution, a colloid, or both? Explain.
13.110 What type of colloid is each of the following?
(a) Milk
(b) Fog
(c) Shaving cream
13.111 What is Brownian motion, and what causes it?
13.112 In a movie theater, you can see the beam of projected light. What phenomenon does this exemplify? Why does it occur?
13.113 Why don't soap micelles coagulate and form large glob-

## Finlesassoap mote effective in freshwater or in seawater? Why?

## Comprehensive Problems

13.114 The three aqueous ionic solutions below have total volumes of 25 mL in $\mathrm{A}, 50 \mathrm{~mL}$ in B , and $100 . \mathrm{mL}$ in C. If each sphere represents 0.010 mol of ions, calculate: (a) the total molarity of ions for each solution; (b) the highest molarity of solute; (c) the lowest molality of solute (assuming the solution densities are equal); (d) the highest osmotic pressure (assuming ideal behavior).

13.115 An aqueous solution is $10 . \%$ glucose by mass ( $d=$ $1.039 \mathrm{~g} / \mathrm{mL}$ at $20^{\circ} \mathrm{C}$ ). Calculate its freezing point, boiling point at 1 atm , and osmotic pressure.
13.116 Because zinc has nearly the same atomic radius as copper ( $d=8.95 \mathrm{~g} / \mathrm{cm}^{3}$ ), zinc atoms substitute for some copper atoms in the many types of brass. Calculate the density of the brass with (a) 10.0 atom $\% \mathrm{Zn}$ and (b) 38.0 atom $\% \mathrm{Zn}$.
13.117 Gold occurs in seawater at an average concentration of $1.1 \times 10^{-2} \mathrm{ppb}$. How many liters of seawater must be processed to recover 1 troy ounce of gold, assuming $81.5 \%$ efficiency ( $d$ of seawater $=1.025 \mathrm{~g} / \mathrm{mL} ; 1$ troy ounce $=31.1 \mathrm{~g})$ ?
13.118 Use atomic properties to explain why xenon is 11 times as soluble as helium in water at $0^{\circ} \mathrm{C}$ on a mole basis.
13.119 Which of the following best represents a molecular-scale view of an ionic compound in aqueous solution? Explain.

13.120 Four 0.50 m aqueous solutions are depicted below. Assume the solutions behave ideally: (a) Which has the highest boiling point? (b) Which has the lowest freezing point? (c) Can you determine which one has the highest osmotic pressure? Explain.

13.121 Thermal pollution from industrial wastewater causes the DE temperature of river or lake water to increase, whichecan affect fish survival as the concentration of dissolved $\mathrm{O}_{2}$ decreases. Use the following data to find the molarity of $\mathrm{O}_{2}$ at each temperature (assume the solution density is the same as water):

| Temperature <br> $\left({ }^{\circ} \mathrm{C}\right)$ | Solubility of $\mathrm{O}_{2}$ <br> $\left(\mathrm{mg} / \mathrm{kg} \mathrm{H}_{2} \mathbf{O}\right)$ | Density of <br> $\mathbf{H}_{2} \mathrm{O}(\mathrm{g} / \mathrm{mL})$ |
| :---: | :---: | :---: |
| 0.0 | 14.5 | 0.99987 |
| 20.0 | 9.07 | 0.99823 |
| 40.0 | 6.44 | 0.99224 |

13.122 Pyridine (right) is an essential portion of many biologically active compounds, such as nicotine and vitamin $B_{6}$. Like ammonia, it has a nitrogen with a lone pair, which makes it act as a weak base. Because it is miscible in a wide range of solvents, from
 water to benzene, pyridine is one of the most important bases and solvents in organic syntheses. Account for its solubility behavior in terms of intermolecular forces.
13.123 A chemist is studying small organic compounds for their potential use as an antifreeze. When 0.243 g of a compound is dissolved in 25.0 mL of water, the freezing point of the solution is $-0.201^{\circ} \mathrm{C}$. (a) Calculate the molar mass of the compound ( $d$ of water $=1.00 \mathrm{~g} / \mathrm{mL}$ ). (b) Analysis shows that the compound is 53.31 mass $\% \mathrm{C}$ and 11.18 mass $\% \mathrm{H}$, the remainder being O . Calculate the empirical and molecular formulas of the compound. (c) Draw a Lewis structure for a compound with this formula that forms H bonds and another for one that does not.
13.124 Air in a smoky bar contains $4.0 \times 10^{-6} \mathrm{~mol} / \mathrm{L}$ of CO. What mass of CO is inhaled by a bartender who respires at a rate of $11 \mathrm{~L} / \mathrm{min}$ during an 8.0-h shift?
13.125 Is 50\% by mass of methanol dissolved in ethanol different from $50 \%$ by mass of ethanol dissolved in methanol? Explain.
13.126 Three gaseous mixtures of $\mathrm{N}_{2}$ (blue), $\mathrm{Cl}_{2}$ (green), and Ne (purple) are depicted below. (a) Which has the smallest mole fraction of $\mathrm{N}_{2}$ ? (b) Which have the same mole fraction of Ne ? (c) Rank all three in order of increasing mole fraction of $\mathrm{Cl}_{2}$.

13.127 A water treatment plant needs to attain a fluoride concentration of $4.50 \times 10^{-5} \mathrm{M}$. (a) What mass of NaF must be added to a 5000 .-L blending tank of water? (b) What mass per day of fluoride is ingested by a person who drinks 2.0 L of this water?
13.128 Answer each of the following briefly: (a) Why is cake alum $\left[\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}\right]$ added during water purification? (b) Why is water that contains large amounts of $\mathrm{Ca}^{2+}$ and $\mathrm{Mg}^{2+}$ difficult to use for cleaning? (c) What is the meaning of "reverse" in reverse osmosis? (d) Why might a water treatment plant use ozone as a disinfectant instead of chlorine? (e) How does passing a saturated NaCl solution through a "spent" ion-exchange resin regenerate the resin?
13.129 Four $U$ tubes each have distilled water in the right arm, a solution in the left arm, and a semipermeable membrane between arms. (a) If the solute is KCl , which solution is most concentrated? (b) If each solute is different but all the solutions have the same mofarity, whichcontanns the smallest number of dissolved ions?

$13.130 \beta$-Pinene $\left(\mathrm{C}_{10} \mathrm{H}_{16}\right)$ and $\alpha$-terpineol $\left(\mathrm{C}_{10} \mathrm{H}_{18} \mathrm{O}\right)$ are used in cosmetics to provide a "fresh pine" scent. At 367 K , the pure substances have vapor pressures of 100.3 torr and 9.8 torr, respectively. What is the composition of the vapor (in terms of mole fractions) above a solution containing equal masses of these compounds at 367 K ? (Assume ideal behavior.)
13.131 A solution of 1.50 g of solute dissolved in 25.0 mL of $\mathrm{H}_{2} \mathrm{O}$ at $25^{\circ} \mathrm{C}$ has a boiling point of $100.45^{\circ} \mathrm{C}$. (a) What is the molar mass of the solute if it is a nonvolatile nonelectrolyte and the solution behaves ideally ( $d$ of $\mathrm{H}_{2} \mathrm{O}$ at $25^{\circ} \mathrm{C}=0.997 \mathrm{~g} / \mathrm{mL}$ )? (b) Conductivity measurements show the solute to be ionic of general formula $A B_{2}$ or $A_{2} B$. What is the molar mass if the solution behaves ideally? (c) Analysis indicates an empirical formula of $\mathrm{CaN}_{2} \mathrm{O}_{6}$. Explain the difference between the actual formula mass and that calculated from the boiling point elevation. (d) Find the van't Hoff factor $(i)$ for this solution.
13.132 A pharmaceutical preparation made with ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ is contaminated with methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$. A sample of vapor above the liquid mixture contains a $97 / 1$ mass ratio of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ to $\mathrm{CH}_{3} \mathrm{OH}$. What is the mass ratio of these alcohols in the liquid? At the temperature of the liquid, the vapor pressures of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ and $\mathrm{CH}_{3} \mathrm{OH}$ are 60.5 torr and 126.0 torr, respectively.
13.133 Water treatment plants commonly use chlorination to destroy bacteria. A byproduct is chloroform $\left(\mathrm{CHCl}_{3}\right)$, a suspected carcinogen, produced when HOCl , formed by reaction of $\mathrm{Cl}_{2}$ and water, reacts with dissolved organic matter. The United States, Canada, and the World Health Organization have set a limit of 100. ppb of $\mathrm{CHCl}_{3}$ in drinking water. Convert this concentration into molarity, molality, mole fraction, and mass percent.
13.134 A saturated $\mathrm{Na}_{2} \mathrm{CO}_{3}$ solution is prepared, and a small excess of solid is present (white pile in beaker). A seed crystal of $\mathrm{Na}_{2}{ }^{14} \mathrm{CO}_{3}\left({ }^{14} \mathrm{C}\right.$ is a radioactive isotope of ${ }^{12} \mathrm{C}$ ) is added (small red piece), and the radioactivity is measured over time. (a) Would you expect radioactivity in the solution? Explain.
 (b) Would you expect radioactivity in all the solid or just in the seed crystal? Explain.
13.135 A biochemical engineer isolates a bacterial gene fragment and dissolves a $10.0-\mathrm{mg}$ sample in enough water to make 30.0 mL of solution. The osmotic pressure of the solution is 0.340 torr at $25^{\circ} \mathrm{C}$. (a) What is the molar mass of the gene fragment? (b) If the solution density is $0.997 \mathrm{~g} / \mathrm{mL}$, how large is the freezing point depression for this solution ( $K_{\mathrm{f}}$ of water $=1.86^{\circ} \mathrm{C} / \mathrm{m}$ )?
13.136 A river is contaminated with $0.65 \mathrm{mg} / \mathrm{L}$ of dichloroethylene $\left(\mathrm{C}_{2} \mathrm{H}_{2} \mathrm{Cl}_{2}\right)$. What is the concentration (in $\mathrm{ng} / \mathrm{L}$ ) of dichloroethylene at $21^{\circ} \mathrm{C}$ in the air breathed by a person swimming in the river $\left(k_{\mathrm{H}}\right.$ for $\mathrm{C}_{2} \mathrm{H}_{2} \mathrm{Cl}_{2}$ in water is $\left.0.033 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}\right)$ ? 13.137 At an air-water interface, fatty acids such as oleic acid lie in a one-molecule-thick layer (monolayer), with the heads in the water and the tails perpendicular in theaje When 2.50 mgrof oleic acid is placed on a water surface, it forms a circular monolayer 38.6 cm in diameter. Find the surface area (in $\mathrm{cm}^{2}$ ) occupied by one molecule ( $\mathcal{M}$ of oleic acid $=283 \mathrm{~g} / \mathrm{mol}$ ).
13.138 A simple device used for estimating the concentration of total dissolved solids in an aqueous solution works by measuring the electrical conductivity of the solution. The method assumes that equal concentrations of different solids give approximately the same conductivity, and that the conductivity is proportional to concentration. The table below gives some actual electrical conductivities (in arbitrary units) for solutions of selected solids at the indicated concentrations (in ppm by mass):

Conductivity

| Sample | 0 ppm | $5.00 \times 10^{3} \mathrm{ppm}$ | $10.00 \times 10^{3} \mathrm{ppm}$ |
| :--- | :---: | :---: | :---: |
| $\mathrm{CaCl}_{2}$ | 0.0 | 8.0 | 16.0 |
| $\mathrm{~K}_{2} \mathrm{CO}_{3}$ | 0.0 | 7.0 | 14.0 |
| $\mathrm{Na}_{2} \mathrm{SO}_{4}$ | 0.0 | 6.0 | 11.0 |
| Seawater (dil) | 0.0 | 8.0 | 15.0 |
| $\left.\begin{array}{l}\text { Sucrose } \\ \quad 0.0 \\ \left.\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right) \\ \text { Urea } \\ \quad 0.0\end{array}\left(\mathrm{NH}_{2}\right)_{2} \mathrm{C}=\mathrm{O}\right]$ |  | 0.0 | 0.0 |
| $\quad$ |  |  |  |

(a) How reliable are these measurements for estimating concentrations of dissolved solids? (b) For what types of substances might this method have a large error? Why? (c) Based on this method, an aqueous $\mathrm{CaCl}_{2}$ solution has a conductivity of 14.0 units. Calculate its mole fraction and molality.
13.139 Two beakers are placed in a closed container (left). One beaker contains water, the other a concentrated aqueous sugar
solution. With time, the solution volume increases and the water volume decreases (right). Explain on the molecular level.

13.140 The release of volatile organic compounds into the atmosphere is regulated to limit ozone formation. In a laboratory simulation, $5 \%$ of the ethanol in a liquid detergent is released. Thus, a "down-the-drain" factor of 0.05 is used to estimate ethanol emissions from the detergent. The $k_{\mathrm{H}}$ values for ethanol and 2-butoxyethanol $\left(\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{OH}\right)$ are $5 \times 10^{-6} \mathrm{~atm} \cdot \mathrm{~m}^{3} / \mathrm{mol}$ and $1.6 \times 10^{-6} \mathrm{~atm} \cdot \mathrm{~m}^{3} / \mathrm{mol}$, respectively. (a) Estimate a "down-the-drain" factor for 2-butoxyethanol in the detergent. (b) What is the $k_{\mathrm{H}}$ for ethanol in units of $\mathrm{L} \cdot \mathrm{atm} / \mathrm{mol}$ ? (c) Is this value consistent with a value given as $0.64 \mathrm{~Pa} \cdot \mathrm{~m}^{3} / \mathrm{mol}$ ?
13.141 Although other solvents are available, dichloromethane $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ is still often used to "decaffeinate" drinks because the solubility of caffeine in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ is 8.35 times that in water.
(a) A $100.0-\mathrm{mL}$ sample of cola containing 10.0 mg of caffeine is extracted with 60.0 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. What mass of caffeine remains in the aqueous phase? (b) A second identical cola sample is extracted with two successive $30.0-\mathrm{mL}$ portions of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. What mass of caffeine remains in the aqueous phase after each extraction? (c) Which approach extracts more caffeine?
Fis. 142 LHpdeyeu prepare 250.g of 0.150 m aqueous $\mathrm{NaHCO}_{3}$ ? 13.143 Tartaric acid occurs in crystalline residues found in wine vats. It is used in baking powders and as an additive in foods. It contains $32.3 \%$ by mass carbon and $3.97 \%$ by mass hydrogen; the balance is oxygen. When 0.981 g of tartaric acid is dissolved in 11.23 g of water, the solution freezes at $-1.26^{\circ} \mathrm{C}$. Find the empirical and molecular formulas of tartaric acid.
13.144 Methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ and ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ are miscible because the major intermolecular force for each is hydrogen bonding. In some methanol-ethanol solutions, the mole fraction of methanol is higher, but the mass percent of ethanol is higher. What is the range of mole fraction of methanol for these solutions?
13.145 A solution of 5.0 g of benzoic acid $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}\right)$ in 100.0 g of carbon tetrachloride has a boiling point of $77.5^{\circ} \mathrm{C}$.
(a) Calculate the molar mass of benzoic acid in the solution.
(b) Suggest a reason for the difference between the molar mass based on the formula and that found in part (a).
13.146 Derive a general equation that expresses the relationship between the molarity and the molality of a solution. Why are the numerical values of these two terms approximately equal for very dilute aqueous solutions?
13.147 A florist prepares a solution of nitrogen-phosphorus fertilizer by dissolving 5.66 g of $\mathrm{NH}_{4} \mathrm{NO}_{3}$ and 4.42 g of $\left(\mathrm{NH}_{4}\right)_{3} \mathrm{PO}_{4}$ in enough water to make 20.0 L of solution. What are the molarities of $\mathrm{NH}_{4}^{+}$and of $\mathrm{PO}_{4}{ }^{3-}$ in the solution?
13.148 Suppose coal-fired power plants used water in scrubbers to remove $\mathrm{SO}_{2}$ from smokestack gases (see Chemical Connections, p. 256). (a) If the partial pressure of $\mathrm{SO}_{2}$ in the stack gases is $2.0 \times 10^{-3} \mathrm{~atm}$, what is the solubility of $\mathrm{SO}_{2}$ in the scrubber liquid ( $k_{\mathrm{H}}$ for $\mathrm{SO}_{2}$ in water is $1.23 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$ at $200 .{ }^{\circ} \mathrm{C}$ )? (b) From your answer to part (a), why are basic solutions, such as limewater slurries $\left[\mathrm{Ca}(\mathrm{OH})_{2}\right]$, used in scrubbers?
13.149 Urea is a white crystalline solid used as a fertilizer, in the pharmaceutical industry, and in the manufacture of certain polymer resins. Analysis of urea reveals that, by mass, it is $20.1 \%$ carbon, $6.7 \%$ hydrogen, $46.5 \%$ nitrogen and the balance oxygen. (a) Find the empirical formula of urea. (b) A $5.0 \mathrm{~g} / \mathrm{L}$ solution of urea in water has an osmotic pressure of 2.04 atm , measured at $25^{\circ} \mathrm{C}$. What is the molar mass and molecular formula of urea?
13.150 The total concentration of dissolved particles in blood is 0.30 M . An intravenous (IV) solution must be isotonic with blood, which means it must have the same concentration. (a) To relieve dehydration, a patient is given $100 . \mathrm{mL} / \mathrm{h}$ of IV glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$ for 2.5 h . What mass (g) of glucose did she receive? (b) If isotonic saline $(\mathrm{NaCl})$ is used, what is the molarity of the solution? (c) If the patient is given $150 \mathrm{~mL} / \mathrm{h}$ of IV saline for 1.5 h , how many grams of NaCl did she receive?
13.151 Deviations from Raoult's law lead to the formation of azeotropes, constant boiling mixtures that cannot be separated by distillation, making industrial separations difficult. For components $A$ and $B$, there is a positive deviation if the $A-B$ attraction is less than $\mathrm{A}-\mathrm{A}$ and $\mathrm{B}-\mathrm{B}$ attractions ( A and B reject each other), and a negative deviation if the A-B attraction is greater than A-A and $B-B$ attractions. If the $A-B$ attraction is nearly equal to the A-A and B-B attractions, the solution obeys Raoult's law. Explain whether the behavior of each pair will be nearly ideal, have a positive deviation, or a negative deviation: (a) benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ and methanol; (b) water and ethyl acetate; (c) hexane and heptane; (d) methanol and water; (e) water and hydrochloric acid.
13.152 Acrylic acid $\left(\mathrm{CH}_{2}=\mathrm{CHCOOH}\right)$ is a monomer used to make superabsorbent polymers and various compounds for paint and adhesive production. At 1 atm , it boils at $14+3^{\circ}$ Gbutis prome $D E^{\prime}$ to polymerization. Its vapor pressure at $25^{\circ} \mathrm{C}$ is 4.1 mbar . What pressure (in mmHg ) is needed to distill the pure acid at $65^{\circ} \mathrm{C}$ ?
13.153 To effectively stop polymerization, certain inhibitors require the presence of a small amount of $\mathrm{O}_{2}$. At equilibrium with 1 atm of air, the concentration of $\mathrm{O}_{2}$ dissolved in the monomer acrylic acid $\left(\mathrm{CH}_{2}=\mathrm{CHCOOH}\right)$ is $1.64 \times 10^{-3} \mathrm{M}$. (a) What is the $k_{\mathrm{H}}(\mathrm{mol} / \mathrm{L} \cdot \mathrm{atm})$ for $\mathrm{O}_{2}$ in acrylic acid? (b) If 0.005 atm of $\mathrm{O}_{2}$ is sufficient to stop polymerization, what is the molarity of $\mathrm{O}_{2}$ ? (c) What is the mole fraction? (d) What is the concentration in ppm ? (Pure acrylic acid is $14.6 \mathrm{M} ; \mathrm{P}_{\mathrm{O}_{2}}$ in air is 0.2095 atm .)
13.154 Volatile organic solvents have been implicated in adverse health effects of industrial workers. Greener methods are phasing them out (see the margin note, p. 505). Rank the solvents in Table 13.6 (p. 530) in terms of increasing volatility.
13.155 At ordinary temperatures, water is a poor solvent for organic substances. But at high pressure and above $200^{\circ} \mathrm{C}$, water develops many properties of organic solvents. Find the minimum pressure needed to maintain water as a liquid at $200 .{ }^{\circ} \mathrm{C}$ $\left(\Delta H_{\text {vap }}=40.7 \mathrm{~kJ} / \mathrm{mol}\right.$ at $100^{\circ} \mathrm{C}$ and 1.00 atm ; assume it remains constant with temperature).
13.156 In ice-cream making, the ingredients are kept below $0.0^{\circ} \mathrm{C}$ in an ice-salt bath. (a) Assuming that NaCl dissolves completely and forms an ideal solution, what mass of it is needed to lower the melting point of 5.5 kg of ice to $-5.0^{\circ} \mathrm{C}$ ? (b) Given the same assumptions as in part (a), what mass of $\mathrm{CaCl}_{2}$ is needed?
13.157 Perfluorocarbons (PFCs), hydrocarbons with all the H replaced by F, have very weak cohesive forces. One unusual application shows a mouse surviving submerged in $\mathrm{O}_{2}$-saturated PFCs. (a) At 298 K , perfluorohexane $\left(\mathrm{C}_{6} \mathrm{~F}_{14}, \mathcal{M}=338 \mathrm{~g} / \mathrm{mol}\right.$, $d=1.674 \mathrm{~g} / \mathrm{mL}$ ) in equilibrium with $101,325 \mathrm{~Pa}$ of $\mathrm{O}_{2}$ has a
mole fraction of $\mathrm{O}_{2}$ of $4.28 \times 10^{-3}$. What is the $k_{\mathrm{H}}$ in $\mathrm{mol} / \mathrm{L} \cdot \mathrm{atm}$ ? (b) According to one source, the $k_{\mathrm{H}}$ for $\mathrm{O}_{2}$ in water at $25^{\circ} \mathrm{C}$ is $756.7 \mathrm{~L} \cdot \mathrm{~atm} / \mathrm{mol}$. What is the solubility of $\mathrm{O}_{2}$ in water at $25^{\circ} \mathrm{C}$ in ppm ? (c) Rank the $k_{\mathrm{H}}$ values in descending order for $\mathrm{O}_{2}$ in water, ethanol, $\mathrm{C}_{6} \mathrm{~F}_{14}$, and $\mathrm{C}_{6} \mathrm{H}_{14}$. Explain your ranking.
13.158 The solubility of $\mathrm{N}_{2}$ in blood is a serious problem for divers breathing compressed air ( $78 \% \mathrm{~N}_{2}$ by volume) at depths greater than 50 ft (see the margin note, p. 522). (a) What is the molarity of $\mathrm{N}_{2}$ in blood at 1.00 atm ? (b) What is the molarity of $\mathrm{N}_{2}$ in blood at a depth of $50 . \mathrm{ft}$ ? (c) Find the volume (in mL ) of $\mathrm{N}_{2}$, measured at $25^{\circ} \mathrm{C}$ and 1.00 atm , released per liter of blood when a diver at a depth of 50 . ft rises to the surface $\left(k_{\mathrm{H}}\right.$ for $\mathrm{N}_{2}$ in water at $25^{\circ} \mathrm{C}$ is $7.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}$ and at $37^{\circ} \mathrm{C}$ is $6.2 \times 10^{-4}$ $\mathrm{mol} / \mathrm{L} \cdot \mathrm{atm}$; assume $d$ of water is $1.00 \mathrm{~g} / \mathrm{mL}$ ).
13.159 Figure 12.9B (p. 448) shows the phase changes of pure water. Consider how the diagram would change if air were present at 1 atm and dissolved in the water. (a) Would the three phases of water still attain equilibrium at some temperature? Explain. (b) In principle, would that temperature be higher, lower, or the same as the triple point for pure water? Explain. (c) Would ice sublime at a few degrees below the freezing point under this pressure? Explain. (d) Would the liquid have the same vapor pressure as that shown in Figure 12.9 B at $100^{\circ} \mathrm{C}$ ? At $120^{\circ} \mathrm{C}$ ?
$13.160 \mathrm{KNO}_{3}, \mathrm{KClO}_{3}, \mathrm{KCl}$, and NaCl are recrystallized as follows: Step 1. A saturated aqueous solution of the compound is prepared at $50^{\circ} \mathrm{C}$.
Step 2. The mixture is filtered to remove undissolved compound. Step 3. The filtrate is cooled to $0^{\circ} \mathrm{C}$.
Step 4. The crystals that form are filtered, dried, and weighed.
(a)FHileh eoppound has the highest percent recovery and which the lowest (see Figure 13.21, p. 520)? (b) Starting with 100.g of each compound, how many grams of each can be recovered?
13.161 Eighty proof whiskey is $40 \%$ ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ by volume. A man has 7.0 L of blood and drinks 28 mL of the whiskey, of which $22 \%$ of the ethanol goes into his blood. (a) What concentration (in $\mathrm{g} / \mathrm{mL}$ ) of ethanol is in his blood ( $d$ of ethanol $=$ $0.789 \mathrm{~g} / \mathrm{mL}$ )? (b) What volume (in mL ) of whiskey would raise his blood alcohol level to $8.0 \times 10^{-4} \mathrm{~g} / \mathrm{mL}$, the level at which a person is considered intoxicated?
13.162 Soft drinks are canned under 4 atm of $\mathrm{CO}_{2}$ and release $\mathrm{CO}_{2}$ when opened (see the margin note, p. 522). (a) How many moles of $\mathrm{CO}_{2}$ are dissolved in a $355-\mathrm{mL}$ can of soda before it is opened? (b) After it has gone flat? (c) What volume (in L ) would the released $\mathrm{CO}_{2}$ occupy at 1.00 atm and $25^{\circ} \mathrm{C}\left(k_{\mathrm{H}}\right.$ for $\mathrm{CO}_{2}$ at $25^{\circ} \mathrm{C}$ is $3.3 \times 10^{-2} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm} ; P_{\mathrm{CO}_{2}}$ in air is $\left.3 \times 10^{-4} \mathrm{~atm}\right)$ ?
13.163 Gaseous $\mathrm{O}_{2}$ in equilibrium with $\mathrm{O}_{2}$ dissolved in water at 283 K is depicted at right. (a) Which scene below represents the system at 298 K ? (b) Which scene represents the system when the pressure of $\mathrm{O}_{2}$ is increased by half?

## 14

Imposing Importance The world's largest periodic table was displayed at the 2006 Chicago Science Expedition in the Richard J. Daley Center to emphasize the importance of science in everyday life. In this chapter, we correlate patterns in the periodic table with patterns in the physical and chemical behavior of the main-group elements.

## Periodic Patterns in the Main-Group Elements

### 14.1 Hydrogen, the Simplest Atom Highlights of Hydrogen Chemistry <br> 14.2 Trends Across the Periodic Table: The Period 2 Elements <br> 14.3 Group 1A(1): The Alkali Metals <br> 14.4 Group 2A(2): The Alkaline Earth Metals <br> 14.5 Group 3A(13): The Boron Family Highlights of Boron Chemistry

14.6 Group 4A(14): The Carbon Family Highlights of Carbon Chemistry Highlights of Silicon Chemistry
14.7 Group 5A(15): The Nitrogen Family Highlights of Nitrogen Chemistry Highlights of Phosphorus Chemistry

### 14.8 Group 6A(16): The Oxygen Family Highlights of Oxygen Chemistry Highlights of Sulfur Chemistry

14.9 Group 7A(17): The Halogens Highlights of Halogen Chemistry
14.10 Group 8A(18): The Noble Gases

In your study of chemistry so far, you've learned how to name compounds, balance equations, and calculate reaction yields. You've seen how heat is related to chemical and physical change, how electron configuration influences atomic properties, how elements bond to form compounds, and how the arrangement of bonding and lone pairs accounts for molecular shapes. You've learned modern theories of bonding and, most recently, seen how atomic and molecular properties give rise to the macroscopic properties of gases, liquids, solids, and solutions.

The purpose of this knowledge, of course, is to make sense of the magnificent diversity of chemical and physical behavior around you. The periodic table, which organizes much of this diversity, was derived from chemical facts observed in countless hours of $18^{\text {th }}$ - and $19^{\text {th }}$-century research. One of the greatest achievements in science is $20^{\text {th }}$-century quantum theory, which provides a theoretical foundation for the periodic table's arrangement. But bear in mind that one theory can rarely account for all the facts. Therefore, be amazed by the predictive power of the patterns in the table, but do not be concerned by the occasional exceptions to these patterns. After all, our models are simple, but nature is complex.

IN THIS CHAPTER . . . We apply general ideas of bonding, structure, and reactivity to the main-group elements and see how their behavior correlates with their position in the periodic table. We begin with hydrogen, the simplest and, in some ways, most important of the elements, and then consider Period 2 to survey the general changes across the periodic table. In each of the remaining sections, we deal with one of the eight families of main-group elements. We explore vertical trends in each group and also keep an eye on horizontal trends involving neighboring groups. Especially important elements-boron, carbon, silicon, nitrogen, phosphorus, oxygen, sulfur, and the halogens-receive greater attention. (If you haven't already read the Interchapter preceding this chapter, now is the perfect time.)

### 14.1 HYDROGEN, THE SIMPLEST ATOM

A hydrogen atom consists of a nucleus with a single positive charge, surrounded by a single electron. Despite this simple structure, or perhaps because of it, hydrogen may be the most important element of all. In the Sun, hydrogen (H) nuclei combine to form helium $(\mathrm{He})$ nuclei in a process that provides nearly all Earth's energy. About $90 \%$ of all the atoms in the universe are H atoms, making it the most abundant element by far. On Earth, only tiny amounts of the free element occur naturally ( as $\mathrm{H}_{2}$ ), but hydrogen is abundant in combination with oxygen in water. Because of its simple structure and low molar mass, nonpolar gaseous $\mathrm{H}_{2}$ is colorless and odorless, and its extremely weak dispersion forces result in very low melting $\left(-259^{\circ} \mathrm{C}\right)$ and boiling points $\left(-253^{\circ} \mathrm{C}\right)$.

## Where Does Hydrogen Fit in the Periodic Table?

Hydrogen has no perfectly suitable position in the periodic table (Figure 14.1). Because of its single valence electron and common +1 oxidation state, some think it almost fits in Group 1A(1). However, unlike the alkali metals, hydrogen shares its electron with nonmetals rather than losing it to them. Moreover, like a nonmetal, it has a relatively high ionization energy ( $\mathrm{IE}=1311 \mathrm{~kJ} / \mathrm{mol}$ ) -much higher than that of lithium ( $\mathrm{IE}=520 \mathrm{~kJ} / \mathrm{mol}$ ), whose IE is the highest in Group 1 A and a much higher electronegativity as well (EN of $\mathrm{H}=2.1$; EN of $\mathrm{Li}=1.0$ ).

Others think hydrogen almost fits in Group 7A(17). Like the halogens, it occurs as diatomic molecules and fills its outer (valence) level either by electron sharing or by gaining one electron from a metal to form a monatomic anion, the hydride ion $\left(\mathrm{H}^{-} ; \mathrm{O} . \mathrm{N} .=-1\right)$. However, hydrogen has a lower electronegativity

## Concepts \& Skills to Review before you study this chapter

- see the Interchapter

Figure 14.1 Where does hydrogen belong? Hydrogen's small size and single electron confer properties that are not fully consistent with the members of any one periodic group. Depending on the property, hydrogen may fit better in Group $1 \mathrm{~A}(1), 4 \mathrm{~A}(14)$, or $7 \mathrm{~A}(17)$.
$(\mathrm{EN}=2.1)$ than any of the halogens (ENs range from 2.2 to 4.0$)$ and lacks their three valence electron pairs. Moreover, the $\mathrm{H}^{-}$ion is rare and reactive, whereas halide ions are common and stable.

And, still others think that, because of a half-filled valence level and similarities in ionization energy, electron affinity, electronegativity, and bond energies, hydrogen fits best in Group 4A(14).

Hydrogen's unique behavior is attributable to its tiny size. Hydrogen has a high IE because its electron is very close to the nucleus, with no inner electrons to shield it from the positive charge. It has a low EN (for a nonmetal) because it has only one proton to attract bonding electrons. In this chapter, hydrogen will appear in either Group $1 \mathrm{~A}(1)$ or $7 \mathrm{~A}(17)$ depending on the property being considered.

## Highlights of Hydrogen Chemistry

In Chapters 12 and 13, we discussed hydrogen bonding and its impact on physical properties (melting and boiling points, heats of fusion and vaporization, and specific heat capacities) and solubilities. You learned that H bonding plays a critical part in stabilizing Earth's climate as well as your body temperature, and you glimpsed its role in the functional structures of biomolecules. In Chapter 6 (see Chemical Connections, p. 258) we considered the possible future use of hydrogen as a fuel, and in Chapter 22 we'll see how hydrogen is used to recover some metals from their ores. Hydrogen is very reactive, combining with nearly every element, so we focus here on the three types of hydrides.

Ionic (Saltlike) Hydrides With very reactive metals, such as those in Group $1 \mathrm{~A}(1)$ and the larger members of Group $2 \mathrm{~A}(2)(\mathrm{Ca}, \mathrm{Sr}$, and Ba ), hydrogen forms saftlike hydrides white, crystalline solids composed of the metal cation and the hydude ien: PDE ERACRCEI

$$
\begin{aligned}
2 \mathrm{Li}(s)+\mathrm{H}_{2}(g) & \longrightarrow 2 \mathrm{LiH}(s) \\
\mathrm{Ca}(s)+\mathrm{H}_{2}(g) & \longrightarrow \mathrm{CaH}_{2}(s)
\end{aligned}
$$

In water, $\mathrm{H}^{-}$is a strong base that pulls $\mathrm{H}^{+}$from surrounding $\mathrm{H}_{2} \mathrm{O}$ molecules to form $\mathrm{H}_{2}$ and $\mathrm{OH}^{-}$:

$$
\mathrm{NaH}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Na}^{+}(a q)+\mathrm{OH}^{-}(a q)+\mathrm{H}_{2}(g)
$$

The hydride ion is also a powerful reducing agent; for example, it reduces $\mathrm{Ti}(\mathrm{IV})$ to the free metal:

$$
\mathrm{TiCl}_{4}(l)+4 \mathrm{LiH}(s) \longrightarrow \mathrm{Ti}(s)+4 \mathrm{LiCl}(s)+2 \mathrm{H}_{2}(g)
$$

Covalent (Molecular) Hydrides Hydrogen reacts with nonmetals to form many covalent hydrides, such as $\mathrm{CH}_{4}, \mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{O}$, and HF. Most are gases consisting of small molecules, but many hydrides of boron and carbon are liquids or solids that consist of much larger molecules. In most covalent hydrides, hydrogen has an oxidation number of +1 because the other nonmetal has a higher electronegativity than hydrogen.

Conditions for preparing the covalent hydrides depend on the reactivity of the other nonmetal. For example, with stable, triple-bonded $\mathrm{N}_{2}$, hydrogen reacts at high temperatures $\left(\sim 400^{\circ} \mathrm{C}\right)$ and pressures $(\sim 250 \mathrm{~atm})$, and the reaction needs a catalyst to proceed at any practical speed:

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \xrightarrow{\text { catalyst }} 2 \mathrm{NH}_{3}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-91.8 \mathrm{~kJ}
$$

Industrial facilities throughout the world use this reaction to produce millions of tons of ammonia each year for fertilizers, explosives, and synthetic fibers. On the
other hand, hydrogen combines rapidly with reactive, single-bonded $F_{2}$, even at extremely low temperatures $\left(-196^{\circ} \mathrm{C}\right)$ :

$$
\mathrm{F}_{2}(\mathrm{~g})+\mathrm{H}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{HF}(\mathrm{~g}) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-546 \mathrm{~kJ}
$$

Metallic (Interstitial) Hydrides Many transition elements form metallic (interstitial) hydrides, in which $\mathrm{H}_{2}$ molecules (and H atoms) occupy the holes in the metal's crystal structure. Thus, such hydrides are not compounds but gas-solid solutions. Also, unlike ionic and covalent hydrides, interstitial hydrides, such as $\mathrm{TiH}_{1.7}$, typically lack a single, stoichiometric formula because the metal can incorporate variable amounts of hydrogen, depending on the pressure and temperature of the gas.

### 14.2 TRENDS ACROSS THE PERIODIC TABLE: THE PERIOD 2 ELEMENTS

Table 14.1 on pages 568 and 569 presents the trends in atomic properties of the Period 2 elements, lithium through neon, and the physical and chemical properties that emerge from them. In general, these trends apply to the other periods as well. Note the following points:

- Electrons fill the one $n s$ and the three $n p$ orbitals according to Pauli's exclusion principle and Hund's rule.
- As a result of increasing nuclear charge and the addition of electrons to orbitals of the same energy level (same $n$ value), atomic size generally decreases, whereas first ionization energy and electronegativity generally increase (see bar graphs on p. 569).
- Metallic character decreases withinoreasing nudfar chargè ãs peronnembers change from metals to metalloids to nonmetals.
- Reactivity is highest at the left and right ends of the period, except for the inert noble gas.
- Bonding between atoms of an element changes from metallic, to covalent in networks, to covalent in individual molecules, to none (noble gases exist as separate atoms). As expected, physical properties, such as melting point, change abruptly at the network/molecule boundary, which occurs in Period 2 between carbon (solid) and nitrogen (gas).
- Bonding between each element and an active nonmetal changes from ionic, to polar covalent, to covalent. Bonding between each element and an active metal changes from metallic to polar covalent to ionic.
- The acid-base behavior of the common element oxide in water changes from basic to amphoteric to acidic as the bond between the element and oxygen becomes more covalent.
- Reducing strength decreases through the metals, and oxidizing strength increases through the nonmetals. In Period 2, common oxidation numbers (O.N.s) equal the A -group number for Li and Be and the A -group number minus eight for O and F . Boron has several O.N.s, Ne has none, and C and N show all possible O.N.s for their groups.
One point that will be coming up frequently but is not shown in Table 14.1 is the anomalous behavior of the Period 2 elements within their groups. Later, we'll highlight some particularly clear examples of such unrepresentative behavior, which arises from the relatively small size and small number of orbitals in the outer energy level of these elements.

Fill 'Er Up with Hydrogen? Dreams of a future hydrogen economy had included metallic hydrides as "storage containers" for hydrogen fuel in cars. Just drive up to your local refueling station, insert a cylinder of H -packed metal in your car, and zip away again! Some metals, such as palladium (see figure) and niobium, and some alloys, such as $\mathrm{LaNi}_{5}$, store large amounts of hydrogen. However, the metals that store the most hydrogen are expensive and heavy and they hold the gas tightest, releasing it only at very high temperatures. As a result, in 1996, U.S. government funding for research on metallic hydrides stopped. Some researchers are keeping the dream alive, however, through their studies of carbon nanotubes, which store large amounts of $\mathrm{H}_{2}$, and of an $\mathrm{Na} / \mathrm{Al}$ alloy that is lightweight, stores $5 \% \mathrm{H}_{2}$ by mass, and releases it below $200^{\circ} \mathrm{C}$.

Table 14.1 Trends in Atomic, Physical, and Chemical Properties of the Period 2 Elements

| Physical Properties |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Appearance |  |  |  |  |
| Metallic character | Metal | Metal | Metalloid | Nonmetal |
| Hardness | Soft | Hard | Very hard | Graphite: soft <br> Diamond: extremely hard |
| Melting point/ boiling point | Low mp for a metal | High mp | Extremely high mp | Extremely high mp |
| Chemical Properties |  |  |  |  |
| General reactivity | Reactive | Low reactivity at room temperature | Low reactivity at room temperature | Low reactivity at room temperature; graphite more reactive |
| Bonding among atoms of element | Metallic | Metallic | Network covalent | Network covalent |
| Bonding with nonmetals | Ionic | Polar covalent | Polar covalent | Covalent ( $\pi$ bonds common) |
| Bonding with metals | Metallic | Metallic | Polar covalent | Polar covalent |
| Acid-base behavior of common oxide | Strongly basic | Amphoteric | Very weakly acidic | Very weakly acidic |
| Redox behavior (O.N.) | Strong reducing agent $(+1)$ | Moderately strong reducing agent $(+2)$ | Complex hydrides good reducing agents $(+3,-3)$ | Every oxidation state from +4 to -4 |

## Relevance/Uses of Element and Compounds

Li soaps for auto grease; thermonuclear bombs; high-voltage, lowweight batteries; treatment of bipolar disorders $\left(\mathrm{Li}_{2} \mathrm{CO}_{3}\right)$

Rocket nose cones; alloys for springs and gears; nuclear reactor parts; x-ray tubes

Cleaning agent (borax); eyewash, antiseptic (boric acid); armor ( $\mathrm{B}_{4} \mathrm{C}$ ); borosilicate glass; plant nutrient

Graphite: lubricant, structural fiber
Diamond: jewelry, cutting tools, protective films
Limestone $\left(\mathrm{CaCO}_{3}\right)$
Organic compounds: drugs, fuels, textiles, etc.

Lithium floating in oil floating on water.

### 14.3 GROUP 1A(1): THE ALKALI METALS

The first group of elements in the periodic table is named for the alkaline (basic) nature of their oxides and for the basic solutions the elements form in water. Group 1A(1) provides the best example of regular trends with no significant exceptions. All the elements in the group-lithium (Li), sodium (Na), potassium $(\mathrm{K})$, rubidium $(\mathrm{Rb})$, cesium $(\mathrm{Cs})$, and rare, radioactive francium $(\mathrm{Fr}) *$-are very reactive metals. The Family Portrait of Group $1 \mathrm{~A}(1)$, on pages 572 and 573, is the first in a series that provides an overview of each of the main groups. Atomic and physical properties are summarized on the left-hand page; representative reactions and some important compounds appear on the right-hand page. Refer to these family portraits during the discussions for supporting information.

## Why Are the Alkali Metals Soft, Low Melting, and Lightweight?

Unlike most metals, the alkali metals are soft: Na has the consistency of cold butter, and K can be squeezed like clay. The alkali metals also have lower melting and boiling points than any other group of metals. Except for Li, they all melt below $100^{\circ} \mathrm{C}$, and Cs melts a few degrees above room temperature. They have lower densities than most metals: Li floats on lightweight household oil (see photo).

The unusual physical behavior of the alkali metals can be traced to their atomic size, the largest in their respective periods, and to the $n s^{1}$ valence electron configuration. Because the single valence electron is relatively far from the nucleus, there is only a weak attraction between the delocalized electrons and the metal-ion cores in the crystal structure. This weak metallic bonding means the alkali metal crystal structure can be easily deformed or broken down, which results in a soft consistency and low melting point. These elements also have the lowest molar masses in their

## Why Are the Alkali Metals So Reactive?

The alkali metals are extremely reactive elements. They are powerful reducing agents and, thus, always occur in nature as $1+$ cations rather than as free metals. (As we discuss in Section 22.4, highly endothermic reduction processes are required to prepare the free metals industrially from their molten salts.) The alkali metals reduce the halogens and form ionic solids in reactions that release large quantities of heat. They reduce the hydrogen in water, reacting vigorously $(\mathrm{Rb}$ and Cs explosively) to form $\mathrm{H}_{2}$ and a metal hydroxide solution. They reduce $\mathrm{O}_{2}$ in the air, and thus tarnish rapidly. Because of this reactivity, Na and K are usually kept under mineral oil (an unreactive liquid) in the laboratory, and Rb and Cs are handled with gloves under an inert argon atmosphere.

The $n s^{1}$ configuration, which is the basis for their physical properties, is also the reason these metals form salts so readily. In a Born-Haber cycle of the reaction between an alkali metal and a nonmetal, for example, the solid metal separates into gaseous atoms, each of the atoms transfers its outer electron to the nonmetal, and the resulting cations and anions attract each other to form an ionic solid (Section 9.2). Properties based on the $n s^{1}$ configuration relate to each step.

1. Low heat of atomization $\left(\Delta H_{\text {atom }}^{\circ}\right)$. Consistent with the alkali metals' low melting and boiling points, their weak metallic bonding leads to low values for $\Delta H_{\text {atom }}^{\circ}$ (the energy needed to convert the solid into individual gaseous atoms), which decrease down the group: ${ }^{\dagger}$

$$
\mathrm{E}(s) \longrightarrow \mathrm{E}(g) \quad \Delta H_{\text {atom }}(\mathrm{Li}>\mathrm{Na}>\mathrm{K}>\mathrm{Rb}>\mathrm{Cs})
$$

[^24]2. Low IE and small ionic radius. Each alkali metal has the largest size and the lowest IE in its period. A great decrease in size occurs when the outer electron is lost: the volume of the $\mathrm{Li}^{+}$ion is less than $13 \%$ that of the Li atom! Thus, Group $1 \mathrm{~A}(1)$ ions are small spheres with considerable charge density.
3. High lattice energy. When Group $1 \mathrm{~A}(1)$ salts crystallize, large amounts of energy are released because the small cations lie close to the anions. Thus, the endothermic atomization and ionization steps are easily outweighed by the highly exothermic formation of the solid. For a given anion, the trend in lattice energy is the inverse of the trend in cation size: as the cation becomes larger, the lattice energy becomes smaller. This steady decrease in lattice energy within the Group $1 \mathrm{~A}(1)$ and $2 \mathrm{~A}(2)$ chlorides is shown in Figure 14.2 .

Despite the strong ionic attractions in the solid, nearly all Group $1 A(1)$ salts are water soluble. The attraction between the ions and water molecules creates a highly exothermic heat of hydration ( $\Delta H_{\text {hydr }}$ ), and a large increase in entropy occurs when ions in the organized crystal become dispersed and hydrated in solution; together, these factors outweigh the high lattice energy.

The magnitude of the hydration energy decreases as ionic size increases:

$$
\mathrm{E}^{+}(g) \longrightarrow \mathrm{E}^{+}(a q) \quad \Delta H=-\Delta H_{\mathrm{hydr}}\left(\mathrm{Li}^{+}>\mathrm{Na}^{+}>\mathrm{K}^{+}>\mathrm{Rb}^{+}>\mathrm{Cs}^{+}\right)
$$

Interestingly, the smaller ions attract water molecules strongly enough to form larger hydrated ions. This size trend has a major effect on the function of nerves, kidneys, and cell membranes because the sizes of $\mathrm{Na}^{+}(a q)$ and $\mathrm{K}^{+}(a q)$, the most common cations in cell fluids, influence their movement in and out of cells.

## The Anomalous Behavior of Lithium

As we noted in discussing Table 14.1, all the Period 2 elements display some anomalous (unrepresentative) behavior within their groups. Even within the regular, predictable trends of Group 1A(b) didas somerypicatpropenties. Th is the only member that forms a simple oxide and nitride, $\mathrm{Li}_{2} \mathrm{O}$ and $\mathrm{Li}_{3} \mathrm{~N}$, on reaction with $\mathrm{O}_{2}$ and $\mathrm{N}_{2}$ in air. Only Li forms molecular compounds with hydrocarbon groups from organic halides:

$$
2 \mathrm{Li}(s)+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{Cl}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{Li}(s)+\mathrm{LiCl}(s)
$$

Organolithium compounds, such as $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{Li}$, are liquids or low-melting solids that dissolve in nonpolar solvents and contain polar covalent ${ }^{\delta-} \mathrm{C}-\mathrm{Li}^{\delta+}$ bonds. They are important reactants in the synthesis of organic compounds.

Because of its small size, $\mathrm{Li}^{+}$has a relatively high charge density. Therefore, it can deform nearby electron clouds to a much greater extent than the other 1A ions can, which increases orbital overlap and gives many lithium salts significant covalent character (Figure 14.3). Thus, $\mathrm{LiCl}, \mathrm{LiBr}$, and LiI are much more soluble in polar organic solvents, such as ethanol and acetone, than are the halides of Na and K , because the lithium halide dipole interacts with these solvents through dipole-dipole forces. The small, highly positive $\mathrm{Li}^{+}$makes dissociation of Li salts into ions more difficult in water; thus, the fluoride, carbonate, hydroxide, and phosphate of Li are much less soluble in water than those of Na and K .

Figure 14.2 Lattice energies of the Group 1A(1) and 2A(2) chlorides. The lattice energy decreases regularly in both groups of metal chlorides as the cations become larger. Lattice energies for the Group 2A chlorides are greater because the 2A cations have higher charge and smaller size.

Figure 14.3 The effect of $\mathrm{Li}^{+}$charge density on a nearby electron cloud. The ability of the $\mathrm{Li}^{+}$ion to deform nearby electron clouds gives rise to many anomalous properties. In this case, $\mathrm{Li}^{+}$polarizes an $\mathrm{I}^{-}$ion, which gives some covalent character to lithium iodide, Lil, as depicted by a space-filling model (A), an electron density contour (B), and an electron density relief map (C).

## Key Atomic and Physical Properties

Group electron configuration is $n s^{1}$. All members have the +1 oxidation state and form an $\mathrm{E}^{+}$ion.

Atoms have the largest size and lowest IE and EN in their periods.

Down the group, atomic and ionic size increase, while IE and EN decrease.

## Physical Properties

Metallic bonding is relatively weak because there is only one valence electron. Therefore, these metals are soft with relatively low melting and boiling points. These values decrease down the group because larger atom cores attract delocalized electrons less strongly.

Large atomic size and low atomic mass result in low density; thus density generally increases down the group because mass increases more than size.

## Some Reactions and Compounds

## Important Reactions

The reducing power of the alkali metals ( E ) is shown in reactions 1 to 4 . Some industrial applications of Group $1 \mathrm{~A}(1)$ compounds are shown in reactions 5 to 7 .

1. The alkali metals reduce H in $\mathrm{H}_{2} \mathrm{O}$ from the +1 to the 0 oxidation state:

$$
2 \mathrm{E}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{E}^{+}(a q)+2 \mathrm{OH}^{-}(a q)+\mathrm{H}_{2}(g)
$$

The reaction becomes more vigorous down

2. The alkali metals reduce oxygen, but the product depends on the metal. Li forms the oxide, $\mathrm{Li}_{2} \mathrm{O} ; \mathrm{Na}$ forms the peroxide, $\mathrm{Na}_{2} \mathrm{O}_{2} ; \mathrm{K}, \mathrm{Rb}$, and Cs form the superoxide, $\mathrm{EO}_{2}$ :

$$
\begin{aligned}
4 \mathrm{Li}(s)+\mathrm{O}_{2}(g) & \longrightarrow 2 \mathrm{Li}_{2} \mathrm{O}(s) \\
\mathrm{K}(s)+\mathrm{O}_{2}(g) & \longrightarrow \mathrm{KO}_{2}(s)
\end{aligned}
$$

In emergency breathing units, $\mathrm{KO}_{2}$ reacts with $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$ in exhaled air to release $\mathrm{O}_{2}$.
3. The alkali metals reduce hydrogen to form ionic (saltlike) hydrides:

$$
2 \mathrm{E}(s)+\mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{EH}(s)
$$

NaH is an industrial base and reducing agent that is used to prepare other reducing agents, such as $\mathrm{NaBH}_{4}$.
4. The alkali metals reduce halogens to form ionic halides:

$$
2 \mathrm{E}(s)+\mathrm{X}_{2} \longrightarrow 2 \mathrm{EX}(s) \quad(\mathrm{X}=\mathrm{F}, \mathrm{Cl}, \mathrm{Br}, \mathrm{I})
$$

5. Sodium chloride is the most important alkali metal halide.
(a) In the Downs process for the production of sodium metal (Section 22.4), reaction 4 is reversed by supplying electricity to molten NaCl :

$$
2 \mathrm{NaC1}(l) \xrightarrow{\text { electricity }} 2 \mathrm{Na}(l)+\mathrm{C1}_{2}(g)
$$

(b) In the chlor-alkali process (Section 22.5 ), $\mathrm{NaCl}(a q)$ is electrolyzed to form several key industrial chemicals:

$$
2 \mathrm{NaCl}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{NaOH}(a q)+\mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g)
$$

(c) In its reaction with sulfuric acid, NaCl forms two major products:

$$
2 \mathrm{NaCl}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{Na}_{2} \mathrm{SO}_{4}(a q)+2 \mathrm{HCl}(g)
$$

Sodium sulfate is important in the paper industry; HCl is essential in steel, plastics, textile, and food production.
6. Sodium hydroxide is used in the formation of bleaching solutions:
$2 \mathrm{NaOH}(a q)+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{NaClO}(a q)+\mathrm{NaCl}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$
7. In an ion-exchange process (Chemical Connections, p. 542), water is "softened" by removal of dissolved hardwater cations, which displace $\mathrm{Na}^{+}$from a resin:

$$
\begin{gathered}
\mathrm{M}^{2+}(a q)+\mathrm{Na}_{2} \mathrm{Z}(s) \longrightarrow \mathrm{MZ}(s)+2 \mathrm{Na}^{+}(a q) \\
(\mathrm{M}=\mathrm{Mg}, \mathrm{Ca} ; \mathrm{Z}=\text { resin })
\end{gathered}
$$

## Important Compounds

1. Lithium chloride and lithium bromide, LiCl and LiBr . Because the $\mathrm{Li}^{+}$ion is so small, Li salts have a high affinity for $\mathrm{H}_{2} \mathrm{O}$ and yet a positive heat of solution. Thus, they are used in dehumidifiers and air-cooling units.
2. Lithium carbonate, $\mathrm{Li}_{2} \mathrm{CO}_{3}$. Used to make porcelain enamels and toughened glasses and as a drug in the treatment of bipolar disorders.
3. Sodium chloride, NaCl . Millions of tons used in the industrial production of $\mathrm{Na}, \mathrm{NaOH}, \mathrm{Na}_{2} \mathrm{CO}_{3} / \mathrm{NaHCO}_{3}, \mathrm{Na}_{2} \mathrm{SO}_{4}$, and HCl or purified for use as table salt.
4. Sodium carbonate and sodium hydrogen carbonate, $\mathrm{Na}_{2} \mathrm{CO}_{3}$ and $\mathrm{NaHCO}_{3}$. Carbonate used as an industrial base and to make glass. Hydrogen carbonate, which releases $\mathrm{CO}_{2}$ at low temperatures $\left(50^{\circ} \mathrm{C}\right.$ to $\left.100^{\circ} \mathrm{C}\right)$, used in baking powder and in fire extinguishers.
5. Sodium hydroxide, NaOH . Most important industrial base; used to make bleach, sodium phosphates, and alcohols.
6. Potassium nitrate, $\mathrm{KNO}_{3}$. Powerful oxidizing agent used in gunpowder and fireworks (see photo).

Versatile Magnesium Magnesium, second of the alkaline earths, forms a tough, adherent oxide coating that prevents further reaction of the metal in air and confers stability for many uses. The metal can be rolled, forged, welded, and riveted into virtually any shape, and it forms strong, low-density alloys: some weigh $25 \%$ as much as steel but are just as strong. Alloyed with aluminum and zinc, magnesium is used for everyday objects, such as camera bodies, luggage, and the "mag" wheels of bicycles and sports cars. Alloyed with the lanthanides (first series of inner transition elements), it is used in objects that require great strength at high temperatures, such as auto engine blocks and missile parts.

Lime: The Most Useful Metal Oxide Calcium oxide (lime) is a slightly soluble, basic oxide that is among the five most heavily produced industrial compounds in the world; it is made by roasting limestone to high temperatures [Group $2 \mathrm{~A}(2)$ Family Portrait, reaction 7, p. 577]. It has essential roles in steelmaking, water treatment, and smokestack scrubbing. Lime reacts with carbon to form calcium carbide, which is used to make acetylene, and with arsenic acid $\left(\mathrm{H}_{3} \mathrm{AsO}_{4}\right)$ to make insecticides for treating cotton, tobacco, and potato plants. Most glass contains about $12 \%$ lime by mass. The paper industry uses lime to prepare the bleach $\left[\mathrm{Ca}(\mathrm{ClO})_{2}\right]$ that whitens paper. Farmers "dust" fields with lime to "sweeten" acidic soil. The food industry uses it to neutralize compounds in milk to make cream and butter and to neutralize impurities in crude sugar.

### 14.4 GROUP 2A(2): THE ALKALINE EARTH METALS

The Group $2 \mathrm{~A}(2)$ elements are called alkaline earth metals because their oxides give basic (alkaline) solutions and melt at such high temperatures that they remained as solids ("earths") in the alchemists' fires. The group includes a fascinating collection of elements: rare beryllium ( Be ), common magnesium $(\mathrm{Mg})$ and calcium $(\mathrm{Ca})$, less familiar strontium $(\mathrm{Sr})$ and barium $(\mathrm{Ba})$, and radioactive radium (Ra). The Group 2A(2) Family Portrait (pp. 576 and 577) presents an overview of these elements.

## How Do the Physical Properties of the Alkaline Earth and Alkali Metals Compare?

In general terms, the elements in Groups $1 \mathrm{~A}(1)$ and $2 \mathrm{~A}(2)$ behave as close cousins. Whatever differences occur between the groups are those of degree, not kind, and are due to the change in outer electron configuration: $n s^{2}$ vs. $n s^{1}$. Two electrons are available from each 2 A atom for metallic bonding, and the nucleus contains one additional positive charge. These factors make the attraction between delocalized electrons and atom cores greater. Consequently, melting and boiling points are much higher for 2 A metals than for the corresponding 1 A metals; in fact, the 2 A elements melt at around the same temperatures as the 1 A elements boil! Compared with transition metals, such as iron and chromium, the alkaline earths are soft and lightweight, but they are much harder and more dense than the alkali metals.

## How Do the Chemical Properties of the Alkaline Earth and Alkali Metals Compare?

The alkatine ear metals Gisplay a rwiden range of chemical behavior than the alkati metals, largely because of the behavior of beryllium, as you'll see shortly. Because the second valence electron lies in the same sublevel as the first, it is not shielded from the additional nuclear charge very well, and so $Z_{\text {eff }}$ is greater. Therefore, Group $2 \mathrm{~A}(2)$ elements have smaller atomic radii and higher ionization energies than Group $1 \mathrm{~A}(1)$ elements. Despite the higher IEs, all the alkaline earths (except Be) form ionic compounds as $2+$ cations. Beryllium behaves differently because so much energy is needed to remove two electrons from this tiny atom that it never forms discrete $\mathrm{Be}^{2+}$ ions, and its bonds are polar covalent.

Like the alkali metals, the alkaline earth metals are strong reducing agents. Each element reduces $\mathrm{O}_{2}$ in air to form the oxide ( Ba also forms the peroxide, $\mathrm{BaO}_{2}$ ). Except for Be and Mg , which form adherent oxide coatings, the alkaline earths reduce $\mathrm{H}_{2} \mathrm{O}$ at room temperature to form $\mathrm{H}_{2}$. And, except for Be , they reduce the halogens, $\mathrm{N}_{2}$, and $\mathrm{H}_{2}$ to form ionic compounds. The Group 2A oxides are strongly basic (except for amphoteric BeO ) and react with acidic oxides to form salts, such as sulfites and carbonates; for example,

$$
\mathrm{SrO}(s)+\mathrm{CO}_{2}(g) \longrightarrow \mathrm{SrCO}_{3}(s)
$$

Natural carbonates, such as limestone and marble, are major structural materials and the commercial sources for most 2 A compounds.

The alkaline earth metals are reactive because the high lattice energies of their compounds more than compensate for the large total IE needed to form the $2+$ cation (Section 9.2). Group 2A salts have much higher lattice energies than Group 1 A salts (see Figure 14.2) because the 2A cations are smaller and doubly charged.

One of the main differences between the two groups is the lower solubility of 2 A salts in water. Their ions are smaller and more highly charged than 1 A ions, resulting in much higher charge densities. Even though this factor increases heats of hydration, it increases lattice energies even more. In fact, most 2 A fluorides, carbonates, phosphates, and sulfates are considered insoluble, unlike the corresponding 1 A compounds. Nevertheless, the ion-dipole attraction of $2+$ ions
for water is so strong that many slightly soluble 2 A salts crystallize as hydrates; two examples are Epsom salt, $\mathrm{MgSO}_{4} \cdot 7 \mathrm{H}_{2} \mathrm{O}$, used as a soak for inflammations, and gypsum, $\mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, used as the bonding material between the paper sheets in wallboard and as the cement in surgical casts.

## The Anomalous Behavior of Beryllium

The Period 2 element Be displays far more anomalous behavior than Li in Group $1 \mathrm{~A}(1)$. If the $\mathrm{Be}^{2+}$ ion did exist, its high charge density would polarize nearby electron clouds very strongly and cause extensive orbital overlap. In fact, all Be compounds exhibit covalent bonding. Even $\mathrm{BeF}_{2}$, the most ionic Be compound, has a relatively low melting point and, when melted, a low electrical conductivity.

With only two valence electrons, Be does not attain an octet in its simple gaseous compounds (Section 10.1). When it bonds to an electron-rich atom, however, this electron deficiency is overcome as the gas condenses. Consider beryllium chloride $\left(\mathrm{BeCl}_{2}\right)$ (Figure 14.4). At temperatures greater than $900^{\circ} \mathrm{C}$, it consists of linear molecules in which two $s p$ hybrid orbitals hold four electrons around the central Be . As it cools, the molecules bond together, solidifying in long chains, with each $\mathrm{Be} s p^{3}$ hybridized to finally attain an octet.

## Diagonal Relationships: Lithium and Magnesium

Figure 14.4 Overcoming electron deficiency in beryllium chloride. A, At high temperatures, $\mathrm{BeCl}_{2}$ is a gas with only four electrons around each Be. B, Solid $\mathrm{BeCl}_{2}$ occurs in long chains with each Cl bridging two Be atoms, which gives each Be an octet.

One of the clearest ways in which atomic properties influence chemical behavior appears in the diagonal relationships, similarities between a Period 2 element and one diagonally down and to the right in Period 3 (Figure 14.5).

## Apago PDF Enhancer

Figure 14.5 Three diagonal relationships in the periodic table. Certain Period 2 elements exhibit behaviors that are very similar to those of the Period 3 elements immediately below and to the right. Three such diagonal relationships exist: Li and $\mathrm{Mg}, \mathrm{Be}$ and Al , and B and Si .

The first of three such relationships occurs between Li and Mg and reflects similarities in atomic and ionic size. Note that one period down increases atomic (or ionic) size and one group to the right decreases it. Thus, Li has a radius of 152 pm and Mg has a radius of 160 pm ; the $\mathrm{Li}^{+}$radius is 76 pm and that of $\mathrm{Mg}^{2+}$ is 72 pm . From similar atomic properties emerge similar chemical properties. Both elements form nitrides with $\mathrm{N}_{2}$, hydroxides and carbonates that decompose easily with heat, organic compounds with a polar covalent metal-carbon bond, and salts with similar solubilities. We'll discuss the diagonal relationships between Be and Al and between B and Si in later sections.

## Looking Backward and Forward: Groups 1A(1), 2A(2), and 3A(13)

Throughout this chapter, comparing the previous, current, and upcoming groups (Figure 14.6) will help you to keep horizontal trends in mind while examining vertical groups. Not much changes from 1 A to 2 A , and the elements behave as metals both physically and chemically. With smaller atomic sizes and stronger metallic bonding, 2A elements are harder, higher melting, and denser than those in 1 A . Nearly all 1 A and most 2 A compounds are ionic. The higher ionic charge in Group 2A $(2+$ vs. $1+)$ leads to higher lattice energies and less soluble salts. The range of behavior in 2 A is wider than that in 1 A because of Be , and the range widens much further in Group 3A, from metalloid boron to metallic thallium.

Figure 14.6 Standing in Group 2A(2), looking backward to 1A(1) and forward to 3A(13).

## Key Atomic and Physical Properties

Group electron configuration is $n s^{2}$ (filled $n s$ sublevel). All members have the +2 oxidation state and, except for Be , form compounds with an $\mathrm{E}^{2+}$ ion.

Atomic and ionic
sizes increase down the group but are smaller than for the corresponding $1 \mathrm{~A}(1)$ element.

IE and EN
decrease down
the group but are higher than for the corresponding 1A(1) element.

## Physical Properties

Metallic bonding involves two valence electrons. These metals are still relatively soft but are much harder than the $1 \mathrm{~A}(1)$ metals.

Melting and boiling points generally decrease, and densities generally increase down the group. These values are much higher than for $1 \mathrm{~A}(1)$ elements, and the trend is not as regular.

## Some Reactions and Compounds

## Important Reactions

The elements (E) act as reducing agents in reactions 1 to 5 ; note the similarity to reactions of Group $1 \mathrm{~A}(1)$. Reaction 6 shows the general basicity of the $2 \mathrm{~A}(2)$ oxides; reaction 7 shows the general instability of their carbonates at high temperature.

1. The metals reduce $\mathrm{O}_{2}$ to form the oxides:
$2 \mathrm{E}(s)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{EO}(s)$ Ba also forms the peroxide, $\mathrm{BaO}_{2}$.

Magnesium ribbon burning

2. The larger metals reduce water to form hydrogen gas:

$$
\begin{aligned}
\mathrm{E}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{E}^{2+}(a q)+2 \mathrm{OH}^{-} & (a q)+\mathrm{H}_{2}(g) \\
& (\mathrm{E}=\mathrm{Ca}, \mathrm{Sr}, \mathrm{Ba})
\end{aligned}
$$

Be and Mg form an adherent oxide coating that allows only slight reaction.
3. The metals reduce halogens to form ionic halides:
$\mathrm{E}(s)+\mathrm{X}_{2}(g) \longrightarrow \mathrm{EX}_{2}(s)[\mathrm{X}=\mathrm{F}$ (not with Be ), $\mathrm{Cl}, \mathrm{Br}, \mathrm{I}]$
4. Most of the elements reduce hydrogen to form ionic hydrides:

$$
\mathrm{E}(s)+\mathrm{H}_{2}(g) \longrightarrow \mathrm{EH}_{2}(s) \quad(\mathrm{E}=\text { all except } \mathrm{Be})
$$

5. Most of the elements reduce nitrogen to form ionic nitrides:

$$
3 \mathrm{E}(s)+\mathrm{N}_{2}(g) \longrightarrow \mathrm{E}_{3} \mathrm{~N}_{2}(s) \quad(\mathrm{E}=\text { all except Be })
$$

6. Except for amphoteric BeO , the element oxides are basic:

$$
\mathrm{EO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{E}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)
$$

$\mathrm{Ca}(\mathrm{OH})_{2}$ is a component of cement and mortar.
7. All carbonates undergo thermal decomposition to the oxide:

$$
\mathrm{ECO}_{3}(\mathrm{~s}) \xrightarrow{\Delta} \mathrm{EO}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g})
$$

This reaction is used to produce CaO (lime) in huge amounts from naturally occurring limestone (margin note, p. 574).

## Apago PDF Enhancer

## Important Compounds

1. Beryl, $\mathrm{Be}_{3} \mathrm{Al}_{2} \mathrm{Si}_{6} \mathrm{O}_{18}$. Beryl, the industrial source of Be metal, also occurs as a gemstone with a variety of colors (see photo). It is chemically identical to emerald, except for the trace of $\mathrm{Cr}^{3+}$ that gives emerald its green color.
2. Magnesium oxide, MgO . Because of its high melting point $\left(2852^{\circ} \mathrm{C}\right), \mathrm{MgO}$ is used as a refractory material for furnace brick (see photo) and wire insulation.

3. Alkylmagnesium halides, $\mathrm{RMgX}(\mathrm{R}=$ hydrocarbon group; $\mathrm{X}=$ halogen). These compounds are used to synthesize many organic compounds. Organotin agricultural fungicides are made by treating RMgX with $\mathrm{SnCl}_{4}$ :

$$
3 \mathrm{RMgCl}+\mathrm{SnCl}_{4} \longrightarrow 3 \mathrm{MgCl}_{2}+\mathrm{R}_{3} \mathrm{SnCl}
$$

4. Calcium carbonate, $\mathrm{CaCO}_{3}$. Occurs as enormous natural deposits of limestone, marble, chalk (see photo), and coral. Used as a building material, to make lime, and, in high purity, as a toothpaste abrasive and an antacid.

White cliffs, Dover, England

### 14.5 GROUP 3A(13): THE BORON FAMILY

The third family of main-group elements contains some unusual members and some familiar ones, some exotic bonding, and some strange physical properties. Boron (B) heads the family, but, as you'll see, its properties certainly do not represent the other members. Metallic aluminum ( Al ) has properties that are more typical of the group, but its great abundance and importance contrast with the rareness of gallium (Ga), indium (In), thallium ( Tl ), and especially the recently synthesized element 113. The atomic, physical, and chemical properties of these elements are summarized in the Group 3A(13) Family Portrait (pp. 580 and 581).

## How Do Transition Elements Influence Group 3A(13) Properties?

Group $3 \mathrm{~A}(13)$ is the first of the $p$ block. If you look at the main groups only, the elements of this group seem to be just one group away from those of Group 2A(2). In Period 4 and higher, however, a large gap separates the two groups (see Figure 8.11 , p. 314). The gap holds 10 transition elements ( $d$ block) each in Periods 4,5 , and 6 and an additional 14 inner transition elements ( $f$ block) in Period 6. Recall from Section 8.2 that $d$ and $f$ electrons penetrate very little, and so spend very little time near the nucleus. Thus, the heavier 3 A members- Ga , In, and Tl -have nuclei with many more protons, but their outer ( $s$ and $p$ ) electrons are only partially shielded from the much higher positive charge; as a result, these elements have greater $Z_{\text {eff }}$ values than the two lighter members of the group.

Many properties of these heavier 3A elements are influenced by this stronger nuclear attraction. Figure 14.7 compares several properties of Group $3 \mathrm{~A}(13)$ with those of Group 3B(3) (the first group of transition elements), in which the additional protons of the $d$ block and $f$ block have not been added. Note the regular changes exhibitedlyy the 3Brelementsincontrast to the irregular patterns for those in 3A. The deviations for Ga reflect the $d$-block contraction in size and can be explained by limited shielding by the $d$ electrons of the 10 additional protons of the first transition series. Similarly, the deviations for Tl reflect the $f$-block (lanthanide) contraction and can be explained by limited shielding by the $f$ electrons of the 14 additional protons of the first inner transition series.

Physical properties are influenced by the type of bonding that occurs in the element. Boron is a network covalent metalloid-black, hard, and very high melting. The other group members are metals-shiny and relatively soft and low melting. Aluminum's low density and three valence electrons make it an exceptional conductor: for a given mass, aluminum conducts a current twice as effectively as copper. Gallium has the largest liquid temperature range of any element: it melts in your hand (see photo, p. 580) but does not boil until $2403^{\circ} \mathrm{C}$. Its metallic bonding is too weak to keep the Ga atoms fixed when the solid is warmed, but strong enough to keep them from escaping the molten metal until it is very hot.

## What New Features Appear in the Chemical Properties of Group 3A(13)?

Looking down Group 3A(13), we see a wide range of chemical behavior. Boron, the anomalous member from Period 2, is the first metalloid we've encountered so far and the only one in the group. It is much less reactive at room temperature than the other members and forms covalent bonds exclusively. Although aluminum acts like a metal physically, its halides exist in the gas phase as covalent dimersmolecules formed by joining two identical smaller molecules (Figure 14.8)—and its oxide is amphoteric rather than basic. Most of the other 3A compounds are ionic, but they have more covalent character than similar 2A compounds. Because the 3 A cations are smaller and more highly charged than the 2 A cations, they polarize an anion's electron cloud more effectively.

The redox behavior of the elements in this group provides a chance to note three general principles that appear in Groups $3 \mathrm{~A}(13)$ to $6 \mathrm{~A}(16)$ :

1. Presence of multiple oxidation states. Many of the larger elements in these groups also have an important oxidation state two lower than the $A$-group number. The lower state occurs when the atoms lose their $n p$ electrons only, not their two $n s$ electrons. This fact is often called the inert-pair effect (Section 8.5), but it has nothing to do with any inertness of $n s$ electrons; for example, the $6 s$ electrons in Tl are lost more easily than the $4 s$ electrons in Ga . The reason for the common appearance of the lower state involves bond energies of the compounds. Bond energy decreases as atomic size, and therefore bond length, increases. Consider the $\mathrm{Tl}-\mathrm{Cl}$ bond. It is relatively long and weak, and it takes more energy to remove the two $6 s$ electrons from $\mathrm{Tl}^{+}$to make $\mathrm{Tl}^{3+}$ than is released when two more weak $\mathrm{Tl}-\mathrm{Cl}$ bonds form in $\mathrm{TlCl}_{3}$. In fact, $\mathrm{TlCl}_{3}$ is so unstable that it decomposes readily to $\mathrm{Cl}_{2}$ gas and TlCl .
2. Increasing prominence of the lower oxidation state. When a group exhibits more than one oxidation state, the lower state becomes more prominent going down the group. In Group $3 \mathrm{~A}(13)$, for instance, all members exhibit the +3 state, but the +1 state first appears with some compounds of gallium and becomes the only important state of thallium.

Figure 14.7 The effect of transition elements on properties: Group $3 \mathrm{~B}(3)$ vs. Group 3A(13). The additional protons in the nuclei of transition elements exert an exceptionally strong attraction because $d$ and $f$ electrons shield the nuclear charge poorly. This greater effective nuclear charge affects the $p$-block elements in Periods 4 to 6, as can be seen by comparing properties of Group 3B(3), the first group after the $s$ block, with those of Group 3A(13), the first group after the d block. A, Atomic size. In Group 3B, size increases smoothly, whereas in 3A, Ga and TI are smaller than expected. B, Total ionization energy for $\mathrm{E}^{3+}$. The deviations in size lead to deviations in total IE $\left(\mathrm{IE}_{1}+\mathrm{IE}_{2}+\mathrm{IE}_{3}\right)$. Note the regular decrease for Group 3B and the unexpectedly higher values for Ga and TI in 3A. C, Electronegativity. The deviations in size also make Ga and TI more electronegative than expected. D, Heat of formation of $\mathrm{EBr}_{3}$. The higher IE values for Ga and TI mean less heat is released upon formation of the ionic compound; thus, the magnitudes of the $\Delta H_{\mathrm{f}}^{\circ}$ values for $\mathrm{GaBr}_{3}$ and $\mathrm{TIBr}_{3}$ are smaller than expected.

Figure 14.8 The dimeric structure of gaseous aluminum chloride. Despite its name, aluminum trichloride exists in the gas phase as the dimer, $\mathrm{Al}_{2} \mathrm{Cl}_{6}$.

## Key Atomic and Physical Properties

## Some Reactions and Compounds

## Important Reactions

In reactions 1 to 3 , the elements ( E ) usually require higher temperatures to react than those of Groups $1 \mathrm{~A}(1)$ and $2 \mathrm{~A}(2)$; note the lower oxidation state of Tl . Reactions 4 to 6 show some compounds in key industrial processes.

1. The elements react sluggishly, if at all, with water:

$$
\begin{gathered}
2 \mathrm{Ga}(s)+6 \mathrm{H}_{2} \mathrm{O}(\text { hot }) \longrightarrow 2 \mathrm{Ga}^{3+}(a q)+6 \mathrm{OH}^{-}(a q)+3 \mathrm{H}_{2}(g) \\
2 \mathrm{Tl}(s)+2 \mathrm{H}_{2} \mathrm{O}(\text { steam }) \longrightarrow 2 \mathrm{Tl}^{+}(a q)+2 \mathrm{OH}^{-}(a q)+\mathrm{H}_{2}(g)
\end{gathered}
$$

Al becomes covered with a layer of $\mathrm{Al}_{2} \mathrm{O}_{3}$ that prevents further reaction (see photo).

Electron micrograph of oxide coating on Al surface

2. When strongly heated in pure $\mathrm{O}_{2}$, all members form oxides:

$$
\begin{aligned}
& 4 \mathrm{E}(s)+3 \mathrm{O}_{2}(g) \xrightarrow{\Delta} 2 \mathrm{E}_{2} \mathrm{O}_{3}(s) \\
& 4 \mathrm{Tl}(s)+\mathrm{O}_{2}(g) \xrightarrow{\Delta} 2 \mathrm{Tl}_{2} \mathrm{O}(s)
\end{aligned} \quad(\mathrm{E}=\mathrm{B}, \mathrm{Al}, \mathrm{Ga}, \mathrm{In})
$$

Oxide acidity decreases down the group: $\mathrm{B}_{2} \mathrm{O}_{3}$ (weakly acidic) $>$ $\mathrm{Al}_{2} \mathrm{O}_{3}>\mathrm{Ga}_{2} \mathrm{O}_{3}>\mathrm{In}_{2} \mathrm{O}_{3}>\mathrm{Tl}_{2} \mathrm{O}$ (strongly basic), and the +1 oxide is more basic than the +3 oxide.
3. All members reduce halogens $\left(\mathrm{X}_{2}\right)$ :

$$
\begin{aligned}
& 2 \mathrm{E}(s)+3 \mathrm{X}_{2} \longrightarrow 2 \mathrm{EX}_{3} \quad(\mathrm{E}=\mathrm{B}, \mathrm{Al}, \mathrm{Ga}, \mathrm{In}) \\
& 2 \mathrm{Tl}(s)+\mathrm{X}_{2} \longrightarrow 2 \mathrm{TlX}(s)
\end{aligned}
$$

The $\mathrm{BX}_{3}$ compounds are volatile and covalent.
Trihalides of Al, Ga, and In are (mostly) ionic solids but occur as covalent dimers in the gas phase; in this way, the 3A atom attains a filled outer level.
4. Acid treatment of $\mathrm{Al}_{2} \mathrm{O}_{3}$ is important in water purification:

$$
\mathrm{Al}_{2} \mathrm{O}_{3}(s)+3 \mathrm{H}_{2} \mathrm{SO}_{4}(l) \longrightarrow \mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}(s)+3 \mathrm{H}_{2} \mathrm{O}(l)
$$

In water, $\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}$ and other agents form a colloid that aids in removing suspended particles (see Chemical Connections, p. 541).
5. The overall reaction in the production of aluminum metal is a redox process:

$$
2 \mathrm{Al}_{2} \mathrm{O}_{3}(s)+3 \mathrm{C}(s) \longrightarrow 4 \mathrm{Al}(s)+3 \mathrm{CO}_{2}(g)
$$

This process is carried out electrochemically in the presence of cryolite $\left(\mathrm{Na}_{3} \mathrm{AlF}_{6}\right)$, which lowers the melting point of the reactant mixture and takes part in the change (Section 22.4).
6. A displacement reaction produces gallium arsenide, GaAs (margin note, p. 578):

$$
\left(\mathrm{CH}_{3}\right)_{3} \mathrm{Ga}(g)+\mathrm{AsH}_{3}(g) \longrightarrow 3 \mathrm{CH}_{4}(g)+\operatorname{GaAs}(s)
$$

## Important Compounds

1. Boron oxide, $\mathrm{B}_{2} \mathrm{O}_{3}$. Used in the production of borosilicate glass (see margin note, $p$. 582).
2. Borax, $\mathrm{Na}_{2}\left[\mathrm{~B}_{4} \mathrm{O}_{5}(\mathrm{OH})_{4}\right] \cdot 8 \mathrm{H}_{2} \mathrm{O}$. Major mineral source of boron compounds and $\mathrm{B}_{2} \mathrm{O}_{3}$. Used as a fireproof insulation material and as a washing powder (20-Mule Team Borax).
3. Boric acid, $\mathrm{H}_{3} \mathrm{BO}_{3}$ [or $\mathrm{B}(\mathrm{OH})_{3}$ ]. Used as external disinfectant, eyewash, and insecticide.
4. Diborane, $\mathrm{B}_{2} \mathrm{H}_{6}$. A powerful reducing agent for possible use as a rocket fuel. Used to synthesize higher boranes, compounds that led to new theories of chemical bonding.

5. Aluminum sulfate (cake alum), $\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}$. Used in purifying water, tanning leather, and sizing paper; as a fixative for dyeing cloth (see photo); and as an antiperspirant.
6. Aluminum oxide, $\mathrm{Al}_{2} \mathrm{O}_{3}$. Major compound in natural source (bauxite) of Al metal. Used as abrasive in sandpaper, sanding and cutting tools, and toothpaste. Large crystals with metal ion Ruby impurities often of gemstone quality
 (see photo). Inert support for chromatography. In fibrous forms, woven into heatresistant fabrics; also used to strengthen ceramics and metals.
7. $\mathrm{Tl}_{2} \mathrm{Ba}_{2} \mathrm{Ca}_{2} \mathrm{Cu}_{3} \mathrm{O}_{10}$. Becomes a high-temperature superconductor at 125 K , which is readily attained with liquid $\mathrm{N}_{2}$ (see photo).

[^25]
3. Relative basicity of oxides. In general, oxides with the element in a lower oxidation state are more basic than oxides with the element in a higher oxidation state. A good example in Group $3 \mathrm{~A}(13)$ is that $\mathrm{In}_{2} \mathrm{O}$ is more basic than $\mathrm{In}_{2} \mathrm{O}_{3}$. In general, when an element has more than one oxidation state, it acts more like a metal in its lower state, and this, too, is related to ionic charge density. In this example, the lower charge of $\mathrm{In}^{+}$does not polarize the $\mathrm{O}^{2-}$ ion as much as the higher charge of $\mathrm{In}^{3+}$ does. Thus, in compounds of general formula $\mathrm{E}_{2} \mathrm{O}$, the E-to-O bonding is more ionic than it is in $\mathrm{E}_{2} \mathrm{O}_{3}$ compounds, so the $\mathrm{O}^{2-}$ ion is more available to act as a base (Interchapter, Topic 4).

## Highlights of Boron Chemistry

Like the other Period 2 elements, the chemical behavior of boron is strikingly different from that of the other members of its group. As was pointed out earlier, all boron compounds are covalent, and unlike the other Group $3 \mathrm{~A}(13)$ members, boron forms network covalent compounds or large molecules with metals, H, $\mathrm{O}, \mathrm{N}$, and C . The unifying feature of many boron compounds is the element's electron deficiency, but boron adopts two strategies to fill its outer level: accepting a bonding pair from an electron-rich atom and forming bridge bonds with electron-poor atoms.
Accepting a Bonding Pair from an Electron-Rich Atom In gaseous boron trihalides $\left(\mathrm{BX}_{3}\right)$, the B atom is electron deficient, with only six electrons around it (Section 10.1). To attain an octet, the $B$ atom accepts a lone pair of electrons from an electron-rich atom (red) and forms a covalent bond:

$$
\mathrm{BF}_{3}(g)+: \mathrm{NH}_{3}(g) \longrightarrow \mathrm{F}_{3} \mathrm{~B}-\mathrm{NH}_{3}(g)
$$

(Such reactions, in which one reactant accepts an electron pair from another to formacgyalent bond nare Ferylwidespread in inorganic, organic, and biochemical processes. They are known as Lewis acid-base reactions, and we'll discuss them in Chapters 18 and 23 and see examples of them throughout the second half of the text.)

Similarly, B has only six electrons in boric acid, $\mathrm{B}(\mathrm{OH})_{3}$ (sometimes written as $\mathrm{H}_{3} \mathrm{BO}_{3}$ ). In water, the acid itself does not release a proton. Rather, it accepts an electron pair from the O in $\mathrm{H}_{2} \mathrm{O}$, forming a fourth bond and releasing an $\mathrm{H}^{+}$ion:

$$
\mathrm{B}(\mathrm{OH})_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{B}(\mathrm{OH})_{4}^{-}(a q)+\mathrm{H}^{+}(a q)
$$

Boron's outer shell is filled in the wide variety of borate salts, such as the mineral borax (sodium borate), $\mathrm{Na}_{2}\left[\mathrm{~B}_{4} \mathrm{O}_{5}(\mathrm{OH})_{4}\right] \cdot 8 \mathrm{H}_{2} \mathrm{O}$, used for decades as a household cleaning agent.

Boron also attains an octet in several boron-nitrogen compounds whose crystal or molecular structures are amazingly similar to those of elemental carbon and some of its organic compounds (Figure 14.9). These similarities are due to the fact that the size, IE, and EN of C are between those of B and $N$ (see Table 14.1). Moreover, C has four valence electrons, whereas B has three and N has five, so the $\cdot \dot{\mathrm{C}}-\dot{\mathrm{C}} \cdot$ and $\cdot \dot{\mathrm{B}}-\dot{\mathrm{N}} \cdot$ groupings have the same number of valence electrons. Therefore, $\mathrm{H}_{3} \mathrm{C}-\mathrm{CH}_{3}$ (ethane) and $\mathrm{H}_{3} \mathrm{~B}-\mathrm{NH}_{3}$ (amine-borane) are isoelectronic, as are benzene and borazine (Figure 14.9A and B ).

Boron nitride (Figure 14.9C) has a structure consisting of hexagons fused into sheets, very similar to that of graphite. Moreover, like graphite, its $\pi$ electrons are highly delocalized through resonance. However, molecular-orbital calculations show that there is a large energy gap between the filled valence band and the empty conductance band in boron nitride, but no such gap in graphite (see Figure 12.38, p. 475). As a result, boron nitride is a white electrical insulator, whereas graphite is a black electrical conductor. At high pressure and temperature, boron nitride forms borazon (Figure 14.9D), which has a crystal structure like that of diamond and is extremely hard and abrasive.

Figure 14.9 Similarities between substances with $\mathrm{C}-\mathrm{C}$ bonds and those with B-N bonds. Note that in each case, B attains an octet of electrons by bonding with electran-rion $N_{N}$ CACSthane andits BN analog. B, Benzene and borazine, which is often referred to as
"inorganic" benzene. C, Graphite and the similar extended hexagonal sheet structure of boron nitride. D, Diamond and borazon have the Fsamecastal struatqre and are among the hardest substances known.

Forming Bridge Bonds with Electron-Poor Atoms In elemental boron and its many hydrides (boranes), there is no electron-rich atom to supply boron with electrons. In these substances, boron attains an octet through some unusual bonding. In diborane $\left(\mathrm{B}_{2} \mathrm{H}_{6}\right)$ and many larger boranes, for example, two types of $\mathrm{B}-\mathrm{H}$ bonds exist. The first type is a typical electron-pair bond. The valence bond picture in Figure 14.10 shows an $s p^{3}$ orbital of B overlapping a $1 s$ orbital of H in each of the four terminal $\mathrm{B}-\mathrm{H}$ bonds, using two of the three electrons in the valence level of each B atom.

The other type of bond is a hydride bridge bond (or three-center, twoelectron bond), in which each $B-H-B$ grouping is held together by only two electrons. Two $s p^{3}$ orbitals, one from each B, overlap an $\mathrm{H} 1 s$ orbital between them. Two electrons move through this extended bonding orbital-one from one of the B atoms and the other from the H atom-and join the two B atoms via the $H$ atom bridge. Notice that each B atom is surrounded by eight electrons: four from the two normal $B-H$ bonds and four from the two $B-H-B$ bridge bonds.

A

Figure 14.10 The two types of covalent bonding in diborane. A, A wedge-bond perspective drawing of $\mathrm{B}_{2} \mathrm{H}_{6}$ shows the unusual $\mathrm{B}-\mathrm{H}-\mathrm{B}$ bridge bond and the tetrahedral arrangement around each $B$ atom. $\mathbf{B}, A$ valence bond depiction shows each $s p^{3}$-hybridized $B$ forming normal covalent bonds with two hydrogens and two bridge bonds, in which two electrons bind three atoms, at the two central $\mathrm{B}-\mathrm{H}-\mathrm{B}$ groupings.

Figure 14.11 The boron icosahedron and one of the boranes. A, The icosahedral structural unit of elemental boron. $B$, The structure of $\mathrm{B}_{5} \mathrm{H}_{9}$, one of many boranes.

In many boranes and in elemental boron (Figure 14.11), one B atom bridges two others in a three-center, two-electron $\mathrm{B}-\mathrm{B}-\mathrm{B}$ bond.

## Diagonal Relationships: Beryllium and Aluminum

Beryllium in Group 2A(2) and aluminum in Group 3A(13) are another pair of diagonally related elements. Both form oxoanions in strong base: beryllate, $\mathrm{Be}(\mathrm{OH})_{4}{ }^{2-}$, and aluminate, $\mathrm{Al}(\mathrm{OH})_{4}{ }^{-}$. Both have bridge bonds in their hydrides and chlorides. Both form oxide coatings impervious to reaction with water, and both oxides are amphoteric, extremely hard, and high melting. Although the atomic and ionic sizes of these elements differ, the small, highly charged $\mathrm{Be}^{2+}$ and $\mathrm{Al}^{3+}$ ions polarize nearby electron clouds strongly. Therefore, some Al compounds and all Be compounds have significant covalent character.

### 14.6 GROUP 4A(14): THE CARBON FAMILY

The whole range of elemental behavior occurs within Group 4A(14): nonmetallic carbon ( C ) leads off, followed by the metalloids silicon $(\mathrm{Si})$ and germanium $(\mathrm{Ge})$, with metallic tin $(\mathrm{Sn})$ and lead $(\mathrm{Pb})$ next, and newly synthesized element 114 at the bottom of the group. Information about the compounds of C and of Si fills libraries: organic chemistry, most polymer chemistry, and biochemistry are based on carbon, whereas geochemistry and some extremely important polymer and electronic technologies are based on silicon. The Group 4A(14) Family Portrait (pp. 586 and 587) summarizes atomic, physical, and chemical properties.

How Does the Bonding in an Element Affect Physical Properties?
 illustrate how physical properties, such as melting point and heat of fusion ( $\Delta H_{\text {fus }}$ ), depend on the type of bonding in an element (Table 14.2). Within Group 4 A , the large decrease in melting point between the network covalent solids C and Si is due to longer, weaker bonds in the Si structure; the large decrease between Ge and Sn is due to the change from covalent network to metallic bonding. Similarly, considering horizontal trends, the large increases in melting point and $\Delta H_{\text {fus }}$ across a period between Al and Si and between Ga and Ge reflect the change from metallic to covalent network bonding. Note the abrupt rises in the values for these properties from metallic $\mathrm{Al}, \mathrm{Ga}$, and Sn to the network covalent metalloids $\mathrm{Si}, \mathrm{Ge}$, and Sb , and note the abrupt drops from the covalent networks of C and Si to the individual molecules of N and P in Group 5A.

Key:

Allotropism: Different Forms of an Element Striking variations in physical properties often appear among allotropes, different crystalline or molecular forms of a substance. One allotrope is usually more stable than another at a particular pressure and temperature. Group $4 \mathrm{~A}(14)$ provides the first dramatic example of allotropism, in the forms of carbon. It is difficult to imagine two substances made entirely of the same atom that are more different than graphite and diamond. Graphite is a black electrical conductor that is soft and "greasy," whereas diamond is a colorless electrical insulator that is extremely hard. Graphite is the standard state of carbon, the more stable form at ordinary temperature and pressure, as the phase diagram in Figure 14.12 shows. Fortunately for jewelry owners, diamond changes to graphite at a negligible rate under normal conditions.

In the mid-1980s, a newly discovered allotrope of carbon began generating great interest. Mass spectrometric analysis of soot had shown evidence for a soccer ball-shaped molecule of formula $\mathrm{C}_{60}$ (Figure 14.13A; see also the Gallery, p. 398). More recently, the molecule has also been found in geological samples formed by meteorite impacts, even the one that occurred around the time the dinosaurs became extinct. The molecule has been dubbed buckminsterfullerene (informally called a "buckyball") after the architect-engineer R. Buckminster Fuller, who designed structures with similar shapes. Excitement rose in 1990, when scientists learned how to prepare multigram quantities of $\mathrm{C}_{60}$ and related fullerenes, enough to study macroscopic behavior and possible applications. Since then, metal atoms have been incorporated into the structure and many different atoms and groups (fluorine, hydroxyl groups, sugars, etc.) have been attached, resulting in compounds with a range of useful properties.

Then, in 1991, scientists passed an electric discharge through graphite rods sealed with helium gas in a container and obtained extremely thin ( $\sim 1 \mathrm{~nm}$ in diameter) graphite-like tubes with fullerene ends (Figure 14.13 B ) These nanotubes are
 also conduct electricity along this axis because of the delocalized electrons. Reports about fullerenes and nanotubes appear almost daily in scientific journals. With potential applications in nanoscale electronics, catalysis, polymers, and medicine, fullerene and nanotube chemistry will receive increasing attention well into the $21^{\text {st }}$ century.

Tin has two allotropes. White $\beta$-tin is stable at room temperature and above, whereas gray $\alpha$-tin is the more stable form below $13^{\circ} \mathrm{C}\left(56^{\circ} \mathrm{F}\right)$. When white tin is kept for long periods at a low temperature, some converts to microcrystals of gray tin. The random formation and growth of these regions of gray tin, which has a different crystal structure, weaken the metal and make it crumble. In the unheated cathedrals of medieval northern Europe, tin pipes of magnificent organs sometimes crumbled as a result of "tin disease" caused by this allotropic transition from white to gray tin.

Figure 14.12 Phase diagram of carbon. Graphite is the more stable form of carbon at ordinary conditions (small red circle at extreme lower left). Diamond is more stable at very high pressure.

Figure 14.13 Buckyballs and
nanotubes. A, Crystals of buckminsterfullerene ( $\mathrm{C}_{60}$ ) next to a ball-and-stick model. The parent of the fullerenes, the "buckyball," is a soccer ball-shaped molecule of 60 carbon atoms. B, Nanotubes are single or, as shown in this colored model, concentric graphite-like tubes (shown here without the usual fullerene ends; see the Gallery, p. 398).

## Key Atomic and Physical Properties

## Some Reactions and Compounds

## Important Reactions

Reactions 1 and 2 pertain to all the elements (E); reactions 3 to 7 concern industrial uses for compounds of C and Si .

1. The elements are oxidized by halogens:

$$
\mathrm{E}(s)+2 \mathrm{X}_{2} \longrightarrow \mathrm{EX}_{4} \quad(\mathrm{E}=\mathrm{C}, \mathrm{Si}, \mathrm{Ge})
$$

The +2 halides are more stable for tin and lead, $\mathrm{SnX} \mathrm{X}_{2}$ and PbX . 2. The elements are oxidized by $\mathrm{O}_{2}$ :

$$
\mathrm{E}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{EO}_{2} \quad(\mathrm{E}=\mathrm{C}, \mathrm{Si}, \mathrm{Ge}, \mathrm{Sn})
$$

Pb forms the +2 oxide, PbO . Oxides become more basic down the group. The reaction of $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ provides the weak acidity of natural unpolluted waters:

$$
\begin{aligned}
\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \rightleftharpoons\left[\mathrm{H}_{2} \mathrm{CO}_{3}(a q)\right] \\
& \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{HCO}_{3}^{-}(a q)
\end{aligned}
$$

3. Air and steam passed over hot coke produce gaseous fuel mixtures (producer gas and water gas):

$$
\mathrm{C}(s)+\operatorname{air}(g)+\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{CO}(g)+\mathrm{CO}_{2}(g)+\mathrm{N}_{2}(g)+\mathrm{H}_{2}(g)
$$

[not balanced]
4. Hydrocarbons react with $\mathrm{O}_{2}$ to form $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$. The reaction for methane is adapted to yield heat or electricity:

$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

Oxyacetylene torch
5. Certain metal carbides react with water to produce acetylene:
$\mathrm{CaC}_{2}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$

$$
\mathrm{Ca}(\mathrm{OH})_{2}(a q)+\mathrm{C}_{2} \mathrm{H}_{2}(g)
$$

The gas is used to make other organic compounds and as a fuel in welding (see photo).
6. Freons (chlorofluorocarbons) are formed by fluorinating carbon tetra-
 chloride:

$$
\mathrm{CCl}_{4}(l)+\mathrm{HF}(g) \longrightarrow \mathrm{CFCl}_{3}(g)+\mathrm{HCl}(g)
$$

Production of trichlorofluoromethane (Freon-11), the most widely used refrigerant in the world, is being eliminated because of adverse effects on the environment (margin note, p. 589). 7. Silica is reduced to form elemental silicon:

$$
\mathrm{SiO}_{2}(s)+2 \mathrm{C}(s) \longrightarrow \mathrm{Si}(s)+2 \mathrm{CO}(g)
$$

This crude silicon is made ultrapure through zone refining (Gallery, p. 533) for the manufacture of computer chips (see photo).

Computer chip

## Important Compounds

1. Carbon monoxide, CO. Used as a gaseous fuel, as a precursor for organic compounds, and as a reactant in the purification of nickel. Formed in internal combustion engines and released as a toxic air pollutant.
2. Carbon dioxide, $\mathrm{CO}_{2}$. Atmospheric component used by photosynthetic plants to make carbohydrates and $\mathrm{O}_{2}$.
The final oxidation product of all carbon-based fuels; its increase in the atmosphere is changing Earth's climate. Used industrially as a refrigerant gas, a blanketing gas in fire extinguishers, and an effervescent gas in beverages (see photo). Combined with $\mathrm{NH}_{3}$ to form urea for fertilizers and plastics manufacture.

3. Methane, $\mathrm{CH}_{4}$. Used as a fuel and in the production of many organic compounds. Major component of natural gas. Formed by anaerobic decomposition of plants (swamp gas) and by microbes in termites and certain mammals. Greenhouse gas that contributes to global warming.
4. Silicon dioxide, $\mathrm{SiO}_{2}$. Occurs in many amorphous (glassy) and crystalline forms, quartz being the most common. Used to make glass and as an inert chromatography support material.
5. Silicon carbide, SiC. Known as carborundum, a major industrial abrasive and a highly refractory ceramic for tough, hightemperature uses. Can be doped to form a high-temperature semiconductor.
6. Organotin compounds, $\mathrm{R}_{4} \mathrm{Sn}$. Used to stabilize PVC [poly(vinyl chloride)] plastics and to cure silicone rubbers.
Agricultural biocide for insects, fungi, and weeds.
7. Tetraethyl lead, $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{~Pb}$. Once used as a gasoline additive to improve fuel efficiency, but now banned because of its inactivation of auto catalytic converters. Major source of lead as a toxic air pollutant.

## How Does the Type of Bonding Change in Group 4A(14) Compounds?

The Group 4A(14) elements display a wide range of chemical behavior, from the covalent compounds of carbon to the ionic compounds of lead. Carbon's intermediate EN of 2.5 ensures that it virtually always forms covalent bonds, but the larger members of the group form bonds with increasing ionic character. With nonmetals, Si and Ge form strong polar covalent bonds, such as the $\mathrm{Si}-\mathrm{O}$ bond, one of the strongest of any Period 3 element $(\mathrm{BE}=368 \mathrm{~kJ} / \mathrm{mol})$. This bond is responsible for the physical and chemical stability of Earth's solid surface, as we discuss later in this section. Although individual Sn or Pb ions rarely exist, the bonding of either element with a nonmetal has considerable ionic character.

The pattern of elements with more than one oxidation state that we observed in Group $3 \mathrm{~A}(13)$ also appears here. After Si , the shift to greater importance of the lower oxidation state occurs: compounds with Si in the +4 state are much more stable than those with Si in the +2 state, whereas compounds with Pb in the +2 state are more stable than those with Pb in the +4 state. The elements also behave more like metals in the lower oxidation state. Consider the chlorides and oxides of Sn and Pb . The +2 chlorides $\mathrm{SnCl}_{2}$ and $\mathrm{PbCl}_{2}$ are white, relatively high-melting, water-soluble crystals-typical properties of a salt (Figure 14.14). In contrast, $\mathrm{SnCl}_{4}$ is a volatile, benzene-soluble liquid, and $\mathrm{PbCl}_{4}$ is a thermally unstable oil. Both likely consist of individual, tetrahedral molecules. The +2 oxides SnO and PbO are more basic than the +4 oxides $\mathrm{SnO}_{2}$ and $\mathrm{PbO}_{2}$ : because the +2 metals are less able to polarize the $\mathrm{O}^{2-}$ ion, the E-to-O bonding is more ionic.

## Highlights of Carbon Chemistry

Like the other Period 2 elements, carbon is an anomaly in its group; indeed, it may be an anomaly in the entire periodic table. Carbon forms bonds with the smaller Group $1 \mathrm{~A}(1)$ and $2 \mathrm{~A}(2)$ metals, many transition metals, the halogens, and its neighbors $\mathrm{B}, \mathrm{Si}, \mathrm{N}, \mathrm{O}, \mathrm{P}$, and S . It also exhibits every oxidation state possible for its group, from +4 in $\mathrm{CO}_{2}$ and halides like $\mathrm{CCl}_{4}$ through -4 in $\mathrm{CH}_{4}$.

Two features stand out in the chemistry of carbon: its ability to bond to itself to form chains, a process known as catenation, and its ability to form multiple bonds. As a result of its small size and its capacity for four bonds, carbon can form chains, branches, and rings that lead to myriad structures. Add a lot of H , some O and N , a bit of $\mathrm{S}, \mathrm{P}$, halogens, and a few metals, and you have the whole organic world! Figure 14.15 shows three of the several million organic compounds known. Multiple bonds are common in carbon structures because the $\mathrm{C}-\mathrm{C}$ bond is short enough for side-to-side overlap of two half-filled $2 p$ orbitals to form $\pi$ bonds. (In Chapter 15, we discuss in detail how the atomic properties of carbon give rise to the diverse structures and reactivities of organic compounds.)

Because the other 4A members are larger, $\mathrm{E}-\mathrm{E}$ bonds become longer and weaker down the group; thus, in terms of bond strength, $\mathrm{C}-\mathrm{C}>\mathrm{Si}-\mathrm{Si}>$ $\mathrm{Ge}-\mathrm{Ge}$. The empty $d$ orbitals of these larger atoms make the chains much more

Acrylonitrile

PCB

Lysine

Figure 14.15 Three of the several million known organic compounds of carbon. Acrylonitrile, a precursor of acrylic fibers.

A typical PCB (one of the polychlorinated biphenyls). Lysine, one of about 20 amino acids that occur in proteins.
susceptible to chemical attack. Thus, some compounds with long Si chains are known but they are very reactive, and the longest Ge chain has only eight atoms. Moreover, longer bonds do not typically allow sufficient overlap of $p$ orbitals for $\pi$ bonding. Only very recently have compounds with $\pi$ bonds between Si atoms or between Ge atoms been prepared, and they are also extremely reactive.

In contrast to its organic compounds, carbon's inorganic compounds are simple. Metal carbonates are the main mineral form. Marble, limestone, chalk, coral, and several other types are found in enormous deposits throughout the world. Many of these compounds are remnants of fossilized marine organisms. Carbonates are used in several common antacids because they reachwith the HC in stomach acid [see the Group 2A(2) Family Portrait, compound 4, p. 577]:

$$
\mathrm{CaCO}_{3}(s)+2 \mathrm{HCl}(a q) \longrightarrow \mathrm{CaCl}_{2}(a q)+\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Identical net ionic reactions with sulfuric and nitric acids protect lakes bounded by limestone deposits from the harmful effects of acid rain.

Unlike the other 4A members, which form only solid network-covalent or ionic oxides, carbon forms two common gaseous oxides, $\mathrm{CO}_{2}$ and CO . Carbon dioxide is essential to all life: it is the primary source of carbon in plants and animals through photosynthesis. Its aqueous solution is the cause of acidity in natural waters. However, its atmospheric buildup from deforestation and excessive use of fossil fuels is severely affecting the global climate. Carbon monoxide forms when carbon or its compounds burn in an inadequate supply of $\mathrm{O}_{2}$ :

$$
2 \mathrm{C}(s)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}(g)
$$

Carbon monoxide is a key component of syngas fuels (see Chemical Connections, p. 256) and is widely used in the production of methanol, formaldehyde, and other major industrial compounds.

CO binds strongly to many transition metals. When inhaled in cigarette smoke or polluted air, it enters the blood and binds strongly to the $\mathrm{Fe}(\mathrm{II})$ in hemoglobin, preventing the normal binding of $\mathrm{O}_{2}$, and to other iron-containing proteins. The cyanide ion $\left(\mathrm{CN}^{-}\right)$is isoelectronic with CO:

$$
[: \mathrm{C} \equiv \mathrm{~N}:]^{-} \quad \text { same electronic structure as } \quad: \mathrm{C} \equiv \mathrm{O}:
$$

Cyanide binds to many of the same iron-containing proteins and is also toxic.
Monocarbon halides (or halomethanes) are tetrahedral molecules whose stability to heat and light decreases as the size of the halogen atom increases and the $\mathrm{C}-\mathrm{X}$ bond becomes longer (weaker) (see the Interchapter, Topic 2). The chlorofluorocarbons (CFCs, or Freons) have important industrial uses; their short, strong carbon-halogen bonds are exceptionally stable, however, and the environmental persistence of these compounds has created major problems.

CFCs: The Good, the Bad, and the Strong The strengths of the $\mathrm{C}-\mathrm{F}$ and $\mathrm{C}-\mathrm{Cl}$ bonds make CFCs, such as Freon$12\left(\mathrm{CCl}_{2} \mathrm{~F}_{2}\right)$, shown here, both useful and harmful. Chemically and thermally stable, nontoxic, and nonflammable, they are excellent cleaners for electronic parts, coolants in refrigerators and air conditioners, and propellants in aerosol cans. However, their bond strengths also mean that CFCs decompose very slowly near Earth's surface. In the lower atmosphere, they contribute to climate warming, absorbing infrared radiation 16,000 times as effectively as $\mathrm{CO}_{2}$. Once in the stratosphere, however, they are bombarded by ultraviolet (UV) radiation, which breaks the otherwise stable $\mathrm{C}-\mathrm{Cl}$ bonds, releasing free Cl atoms that initiate ozone-destroying reactions (Chapter 16). Legal production of CFCs has ended in the United States, but international production and smuggling are widespread.

Figure 14.16 The impact of $p, d-\pi$ bonding on the structure of trisilylamine. A, The molecular shape of trimethylamine is trigonal pyramidal, like that of ammonia. B, Trisilylamine, the silicon analog, has a trigonal planar shape because of the formation of a double bond
between N and Si . The ball-and-stick model shows one of three resonance forms. $\mathbf{C}$, The lone pair in an unhybridized $p$ orbital of N overlaps with an empty $d$ orbital of Si to give a $p, d-\pi$ bond. In the resonance hybrid, a $d$ orbital on each Si is involved in the $\pi$ bond.

## Highlights of Silicon Chemistry

Silicon halides are more reactive than carbon halides because Si has empty $d$ orbitals that are available for bond formation. Surprisingly, the silicon halides have longer yet stronger bonds than the corresponding carbon halides (see Table 9.2, p. 353). One explanation for this unusual strength is that the $\mathrm{Si}-\mathrm{X}$ bond has some double-bond character because of the presence of a $\sigma$ bond and a different type of $\pi$ bond, called a $p, d-\pi$ bond. This bond arises from side-to-side overlap of an Si $d$ orbital and a halogen $p$ orbital. A similar type of $p, d-\pi$ bonding leads to the trigonal planar molecular shape of trisilylamine, in contrast to the trigonal pyramidal shape of trimethylamine (Figure 14.16).

To a great extent the chemistry of silicon is the chemistry of the silicon-oxygen bont. Fust as carbon forms Zmending eet chains, the - $\mathrm{Si}-\mathrm{O}-$ grouping repeats itself endlessly in a wide variety of silicates, the most important minerals on the planet, and in silicones, synthetic polymers that have many applications:

1. Silicate minerals. From common sand and clay to semiprecious amethyst and carnelian, silicate minerals are the dominant form of matter in the nonliving world. Oxygen, the most abundant element on Earth, and silicon, the next most abundant, compose these minerals and thus account for four of every five atoms on the surface of the planet!

The silicate building unit is the orthosilicate grouping, $-\mathrm{SiO}_{4}-$, a tetrahedral arrangement of four oxygens around a central silicon. Several well-known minerals contain $\mathrm{SiO}_{4}{ }^{4-}$ ions or small groups of them linked together. The gemstone zircon $\left(\mathrm{ZrSiO}_{4}\right)$ contains one unit; hemimorphite $\left[\mathrm{Zn}_{4}(\mathrm{OH})_{2} \mathrm{Si}_{2} \mathrm{O}_{7} \cdot \mathrm{H}_{2} \mathrm{O}\right]$ contains two units linked through an oxygen corner; and beryl $\left(\mathrm{Be}_{3} \mathrm{Al}_{2} \mathrm{Si}_{6} \mathrm{O}_{18}\right)$, the major source of beryllium, contains six units joined into a cyclic ion (Figure 14.17). As you'll see shortly, in addition to these separate ions, $\mathrm{SiO}_{4}$ units are linked more extensively to create much of the planet's mineral structure.
2. Silicone polymers. Unlike the naturally occurring silicates, silicone polymers are manufactured substances, consisting of alternating Si and O atoms with two organic groups also bonded to each Si atom. A key starting material is formed by the reaction of silicon with methyl chloride:

$$
\mathrm{Si}(s)+2 \mathrm{CH}_{3} \mathrm{Cl}(\mathrm{~g}) \xrightarrow[\sim 300^{\circ} \mathrm{C}]{\text { Cu catalyst }}\left(\mathrm{CH}_{3}\right)_{2} \mathrm{SiCl}_{2}(\mathrm{~g})
$$

Although the corresponding carbon compound $\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CCl}_{2}\right]$ is inert in water, the empty $d$ orbitals of Si make $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{SiCl}_{2}$ reactive:

$$
\left(\mathrm{CH}_{3}\right)_{2} \mathrm{SiCl}_{2}(l)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow\left(\mathrm{CH}_{3}\right)_{2} \mathrm{Si}(\mathrm{OH})_{2}(l)+2 \mathrm{HCl}(g)
$$

$\mathrm{SiO}_{4}{ }^{4-}$

Silicate ion in zircon

$\mathrm{Si}_{2} \mathrm{O}_{7}{ }^{6-}$
Silicate ion in hemimorphite

Silicate ion in beryl

Figure 14.17 Structures of the silicate anions in some minerals.

The product reacts with itself to form water and a silicone chain molecule called a poly(dimethyl siloxane):

Silicones have properties of both plastics and minerals. The organic groups give them the flexibility and weak intermolecular forces, between chains that are characteristic of a plastic, while the O 영 8 backbone confers the thermai stability and nonflammability of a mineral. In the Gallery on the following pages, note the structural parallels between silicates and silicones.

## Diagonal Relationships: Boron and Silicon

The final diagonal relationship that we consider occurs between the metalloids boron and silicon. Both of these elements exhibit the electrical properties of a semiconductor (Section 12.6). Both B and Si and their mineral oxoanionsborates and silicates-occur in extended covalent networks. Both boric acid $\left[\mathrm{B}(\mathrm{OH})_{3}\right]$ and silicic acid $\left[\mathrm{Si}(\mathrm{OH})_{4}\right]$ are weakly acidic solids that occur as layers held together by widespread H bonding. Their hydrides-the compact boranes and the extended silanes-are both flammable, low-melting compounds that act as reducing agents.

## Looking Backward and Forward: Groups 3A(13), 4A(14), and 5A(15)

Standing in Group 4A(14), we look back at Group 3A(13) as the transition from the $s$ block of metals to the $p$ block of mostly metalloids and nonmetals (Figure 14.18). Major changes in physical behavior occur moving across a period from metals to covalent networks. Changes in chemical behavior occur as well, as cations give way to covalent tetrahedra. Looking ahead to Group 5A(15), we note the more frequent occurrence of covalent bonding and (as electronegativity increases) the expanded valence shells of nonmetals, as well as the first appearance of monatomic anions.

Figure 14.18 Standing in Group 4A(14), looking backward to 3A(13) and forward to $5 \mathrm{~A}(15)$.

## Silicate Minerals and Silicone Polymers

## Silicate Minerals

## Chain Silicates

In the simplest structural class of silicates, each $\mathrm{SiO}_{4}$ unit shares two of its O corners with other $\mathrm{SiO}_{4}$ units, forming a chain. Two chains can link laterally into a ribbon; the most common ribbon has repeating $\mathrm{Si}_{4} \mathrm{O}_{11}{ }^{6-}$ units. Metal ions bind the polyanionic ribbons together into neutral sheaths. With only weak intermolecular forces between sheaths, the material occurs in fibrous strands, as in the family of asbestos minerals.

## Sheet (Layer) Silicates

In the next structural class of silicates, each $\mathrm{SiO}_{4}$ unit shares three of its four O corners with other $\mathrm{SiO}_{4}$ units to form a sheet; double sheets arise when the fourth O is shared with another sheet. In talc, the softest mineral, the sheets interact through weak forces, so talcum powder feels slippery. If Al substitutes for some Si , or if $\mathrm{Al}(\mathrm{OH})_{3}$ layers interleave with silicate sheets, an aluminosilicate results, such as the clay kaolinite. Different substitutions for Si and/or interlayers of other ions give the micas. In muscovite mica, ions lie between aluminosilicate double layers. Mica flakes when the ionic attractions are overcome.

Silicone Polymers

Polymer Chemistry
The design, synthesis, and production of polymers form one of the largest branches of modern chemical science. Nearly half of all industrial chemists and chemical engineers are involved in this pursuit. A major branch of polymer chemistry is devoted to exploring the properties and countless uses of silicones.

Chain Silicones: Oils and Greases
The simplest structural class of silicones consists of the poly(dimethyl siloxane) chain, in which each $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{Si}(\mathrm{OH})_{2}$ unit uses both OH groups to link to two others. A chainterminating compound with a third organic group, such as $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{SiOH}$, is added to control chain length. These polymers are unreactive, oily liquids with high viscosity and low surface tension. They are used as hydraulic oils and lubricants, as antifoaming agents for frying potato chips, and as components of suntan oil, car polish, digestive aids, and makeup.

Sheet Silicones: Elastomers
In the next class of silicones, the third OH group of an added bridging compound, such as $\mathrm{CH}_{3} \mathrm{Si}(\mathrm{OH})_{3}$, reacts to condense chains laterally into gummy sheets that are made into elastomers (rubbers), which are flexible, elastic, and stable from $-100^{\circ} \mathrm{C}$ to $250^{\circ} \mathrm{C}$. These are used in gaskets, rollers, cable insulation, space suits, contact lenses, and dentures.

Makeup consisting of chain and sheet silicones being applied to create the character Freddie Krueger

## Framework Silicones: Resins

In the final structural class of silicones, reactions that free OH groups, while substituting larger organic groups for some $\mathrm{CH}_{3}$ groups, interlink sheets to produce strong, thermally stable resins. These are used as insulating laminates on printed circuit boards and as nonstick coatings on cookware. Sheet and framework silicones have revolutionized modern surgical practice by allowing the fabrication of numerous parts that can be implanted permanently in a patient to replace damaged ones. Some of these (indicated by dots on Leonardo's man) are artificial skin, bone, joints, blood vessels, and organ parts.

### 14.7 GROUP 5A(15): THE NITROGEN FAMILY

For the first two elements of Group 5A(15), gaseous nonmetallic nitrogen (N) and solid nonmetallic phosphorus (P), the industrial and environmental significance of their compounds is matched only by their importance in the structures and functions of biomolecules. Below these nonmetals are two metalloids, arsenic (As) and antimony ( Sb ), followed by the metal bismuth ( Bi ), the last nonradioactive element in the periodic table, and the newly synthesized element 115. The Group 5A(15) Family Portrait (pp. 596 and 597) provides an overview.

## What Accounts for the Wide Range of Physical Behavior in Group 5A(15)?

Group 5A(15) displays the widest range of physical behavior we've seen so far because of large changes in bonding and intermolecular forces. Nitrogen occurs as a gas consisting of $\mathrm{N}_{2}$ molecules, which interact through such weak dispersion forces that the element boils more than $200^{\circ} \mathrm{C}$ below room temperature. Elemental phosphorus exists most commonly as tetrahedral $\mathrm{P}_{4}$ molecules. However, because P is heavier and more polarizable than N , stronger dispersion forces are present, and the element melts about $25^{\circ} \mathrm{C}$ above room temperature. Arsenic consists of extended, puckered sheets in which each As atom is covalently bonded to three others and forms nonbonding interactions with three nearest neighbors in adjacent sheets. This arrangement gives As the highest melting point in the group. A similar covalent network for Sb gives it a much higher melting point than the next member of the group, Bi , which has metallic bonding.

Phosphorus has several allotropes. The white and red forms have very different properties because of the way the atoms are linked. The highly reactive
 cold water to prevent it from igniting in air. It consists of tetrahedral molecules of four P atoms bonded to each other, with no atom in the center (Figure 14.19A). Each P atom uses its half-filled $3 p$ orbitals to bond to the other three. Whereas the $3 p$ orbitals of an isolated P atom lie $90^{\circ}$ apart, the bond angles in $\mathrm{P}_{4}$ are $60^{\circ}$. With the smaller angle comes poor orbital overlap and a $\mathrm{P}-\mathrm{P}$ bond strength only about $80 \%$ that of a normal P-P bond (Figure 14.19B). Weaker bonds break more easily, contributing to the white allotrope's high reactivity. Heating the white form in the absence of air breaks one of the $\mathrm{P}-\mathrm{P}$ bonds in each tetrahedron, and those $3 p$ orbitals overlap with others to form the chains of $\mathrm{P}_{4}$ units that make up the red form (Figure 14.19C). The individual molecules of white P make it highly reactive, low melting $\left(44.1^{\circ} \mathrm{C}\right)$, and soluble in nonpolar solvents; the chains of red P make it much less reactive, high melting ( $\sim 600^{\circ} \mathrm{C}$ ), and insoluble.

Figure 14.19 Two allotropes of phosphorus. A, White phosphorus exists as individual $P_{4}$ molecules, with the $P-P$ bonds forming the edges of a tetrahedron. $\mathbf{B}$, The reactivity of $P_{4}$ is due in part to the bond strain that arises from the $60^{\circ}$ bond angle. Note how overlap of the $3 p$ orbitals is decreased because they do not meet directly end to end (overlap is shown here for only three of the $P$ - $P$ bonds), which makes the bonds easier to break. C, In red phosphorus, one of the $\mathrm{P}-\mathrm{P}$ bonds of the white form has broken and links the $P_{4}$ units together into long chains. Lone pairs (not shown) reside in $s$ orbitals in both allotropes.

Key Atomic and Physical Properties

## Some Reactions and Compounds

## Important Reactions

General group behavior is shown in reactions 1 to 3 , whereas phosphorus chemistry is the theme in reactions 4 and 5.

1. Nitrogen is "fixed" industrially in the Haber process:

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
$$

Further reactions convert $\mathrm{NH}_{3}$ to $\mathrm{NO}, \mathrm{NO}_{2}$, and $\mathrm{HNO}_{3}$ (Highlights of Nitrogen Chemistry). Hydrides of some other group members are formed from reaction in water (or with $\mathrm{H}_{3} \mathrm{O}^{+}$) of a metal phosphide, arsenide, and so forth:
$\mathrm{Ca}_{3} \mathrm{P}_{2}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{PH}_{3}(g)+3 \mathrm{Ca}(\mathrm{OH})_{2}(a q)$
2. Halides are formed by direct combination of the elements:

$$
\begin{array}{cl}
2 \mathrm{E}(s)+3 \mathrm{X}_{2} \longrightarrow 2 \mathrm{EX}_{3} & (\mathrm{E}=\text { all except } \mathrm{N}) \\
\mathrm{EX}_{3}+\mathrm{X}_{2} \longrightarrow \mathrm{EX}_{5} \quad \begin{array}{l}
(\mathrm{E}=\text { all except } \mathrm{N} \text { and Bi } \\
\\
\\
\\
\\
\\
\\
\\
\\
\left.\mathrm{BiCl}_{5} ; \mathrm{E}=\mathrm{E}=\mathrm{P} \text { for } \mathrm{X}=\mathrm{Br}\right)
\end{array}
\end{array}
$$

3. Oxoacids are formed from the halides in a reaction with water that is common to many nonmetal halides:

$$
\begin{array}{r}
\mathrm{EX}_{3}+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{EO}_{3}(a q)+3 \mathrm{HX}(a q) \\
(\mathrm{E}=\text { all except } \mathrm{N}) \\
\mathrm{EX}_{5}+4 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{EO}_{4}(a q)+5 \mathrm{HX}(a q) \\
(\mathrm{E}=\text { all except } \mathrm{N} \text { and } \mathrm{Bi})
\end{array}
$$

Note that the oxidation number of E does not change.
4. Phosphate ions are dehydrated to form polyphosphates:

$$
3 \mathrm{NaH}_{2} \mathrm{PO}_{4}(s) \longrightarrow \mathrm{Na}_{3} \mathrm{P}_{3} \mathrm{O}_{9}(s)+3 \mathrm{H}_{2} \mathrm{O}(g)
$$

5. When $\mathrm{P}_{4}$ reacts in basic solution, its oxidation number both decreases and increases (disproportionation):

$$
\mathrm{P}_{4}(s)+3 \mathrm{OH}^{-}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{PH}_{3}(g)+3 \mathrm{H}_{2} \mathrm{PO}_{2}^{-}(a q)
$$

Analogous reactions are typical of many nonmetals, such as $\mathrm{S}_{8}$ and $\mathrm{X}_{2}$ (halogens).

## Important Compounds

1. Ammonia, $\mathrm{NH}_{3}$. First substance formed when atmospheric $\mathrm{N}_{2}$ is used to make N -containing compounds. Annual multimillion-ton production for use in fertilizers, explosives, rayon, and polymers such as nylon, urea-formaldehyde resins, and acrylics.
2. Hydrazine, $\mathrm{N}_{2} \mathrm{H}_{4}$ (margin note, p. 598).
3. Nitric oxide (NO), nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$, and nitric acid $\left(\mathrm{HNO}_{3}\right)$. Oxides are intermediacid is used in fertilizer manu-

Detonation of explosives facture, nylon production, metal etching, and the explosives industry (Highlights of Nitrogen Chemistry).
4. Amino acids, $\mathrm{H}_{3} \mathrm{~N}^{+}-\mathrm{CH}(\mathrm{R})-\mathrm{COO}^{-}(\mathrm{R}=$ one of 20 different organic groups). Occur in every organism, both free and linked together into proteins. Essential to the growth and function of all cells. Synthetic amino acids are used as dietary supplements.
5. Phosphorus trichloride, $\mathrm{PCl}_{3}$. Used to form many organic phosphorus compounds, including oil and fuel additives, plasticizers, flame retardants, and insecticides. Also used to make $\mathrm{PCl}_{5}, \mathrm{POCl}_{3}$, and other important P -containing compounds. 6. Tetraphosphorus decaoxide $\left(\mathrm{P}_{4} \mathrm{O}_{10}\right)$ and phosphoric acid $\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)$ (Highlights of Phosphorus Chemistry).
7. Sodium tripolyphosphate, $\mathrm{Na}_{5} \mathrm{P}_{3} \mathrm{O}_{10}$. As a water-softening agent (Calgon), it combines with hard-water $\mathrm{Mg}^{2+}$ and $\mathrm{Ca}^{2+}$ ions, preventing them from reacting with soap anions, and thus

Algal growth in polluted lake
improving cleaning action. Its use has been curtailed in the United States because it pollutes lakes and streams by causing excessive algal growth (see photo).
8. Adenosine triphosphate (ATP) and other biophosphates. ATP acts to transfer chemical energy in the cell; it is necessary for all biological processes requiring energy.
Phosphate groups also occur in sugars, fats, proteins, and nucleic acids.
9. Bismuth subsalicylate, $\mathrm{BiO}\left(\mathrm{C}_{7} \mathrm{H}_{5} \mathrm{O}_{3}\right)$.

The active ingredient in Pepto-Bismol (see photo), a widely used remedy for diarrhea and nausea. (The pink color is not due to this white compound.)

Hydrazine, Nitrogen's Other Hydride Aside from $\mathrm{NH}_{3}$, the most important Group $5 \mathrm{~A}(15)$ hydride is hydrazine, $\mathrm{N}_{2} \mathrm{H}_{4}$. Like $\mathrm{NH}_{3}$, it is a weak base, forming $\mathrm{N}_{2} \mathrm{H}_{5}{ }^{+}$and $\mathrm{N}_{2} \mathrm{H}_{6}{ }^{2+}$ ions with acids. Hydrazine is also used to make antituberculin drugs, plant growth regulators, and fungicides, and organic hydrazine derivatives are used in rocket and missile fuels. We might expect the lone pairs in the molecule to lie opposite each other and give a symmetrical structure with no dipole moment. However, repulsions between each lone pair and the bonding pairs on the other atom force the lone pairs to lie below the $\mathrm{N}-\mathrm{N}$ bond (see model), resulting in a large dipole moment ( $\mu=1.85 \mathrm{D}$ in the gas phase). A similar arrangement occurs in hydrogen peroxide $\left(\mathrm{H}_{2} \mathrm{O}_{2}\right)$, the analogous hydride of oxygen.

## What Patterns Appear in the Chemical Behavior of Group 5A(15)?

The same general pattern of chemical behavior that we discussed for Group 4A(14) appears again in this group, reflected in the change from nonmetallic N to metallic Bi. The overwhelming majority of Group 5A(15) compounds have covalent bonds. Whereas N can form no more than four bonds, the next three members can expand their valence shells by using empty $d$ orbitals.

For a 5A element to form an ion with a noble gas electron configuration, it must gain three electrons, the last two in endothermic steps. Nevertheless, the enormous lattice energy released when such highly charged anions attract cations drives their formation. However, the $3-$ anion of N occurs only in compounds with active metals, such as $\mathrm{Li}_{3} \mathrm{~N}$ and $\mathrm{Mg}_{3} \mathrm{~N}_{2}$ (and that of P may occur in $\mathrm{Na}_{3} \mathrm{P}$ ). Metallic Bi forms mostly covalent compounds but exists as a cation in a few compounds, such as $\mathrm{BiF}_{3}$ and $\mathrm{Bi}\left(\mathrm{NO}_{3}\right)_{3} \cdot 5 \mathrm{H}_{2} \mathrm{O}$, through loss of its three valence $p$ electrons.

Again, as we move down this group, we see the patterns first seen in Groups 3 A and 4A. Fewer oxidation states occur, with the lower state becoming more prominent: N exhibits every state possible for a 5 A element, from +5 to -3 ; only the +5 and +3 states are common for P , As , and Sb ; and +3 is the only common state of Bi. The oxides change from acidic to amphoteric to basic, reflecting the increase in the metallic character of the elements. In addition, the lower oxide of an element is more basic than the higher oxide, reflecting the greater ionic character of the E-to-O bonding in the lower oxide.

All the Group $5 \mathrm{~A}(15)$ elements form gaseous hydrides of formula $\mathrm{EH}_{3}$. Except for $\mathrm{NH}_{3}$, these are extremely reactive and poisonous and are synthesized by reaction of a metal phosphide, arsenide, and so forth, which acts as a strong base in water or aqueous acid. For example,

## Apago CBAss $(s)+6 \mathrm{H}_{2} d \mathrm{mac} \mathrm{AAH}_{3}(\mathrm{~g})+3 \mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{aq})$

Ammonia is made industrially by direct combination of the elements at high pressure and moderately high temperature:

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
$$

Molecular properties of the Group 5A(15) hydrides reveal some interesting bonding and structural patterns:

- Despite its much lower molar mass, $\mathrm{NH}_{3}$ melts and boils at higher temperatures than the other 5A hydrides as a result of $H$ bonding.
- Bond angles decrease from $107.3^{\circ}$ for $\mathrm{NH}_{3}$ to around $90^{\circ}$ for the other hydrides, which suggests that the larger atoms use unhybridized $p$ orbitals.
- $\mathrm{E}-\mathrm{H}$ bond lengths increase down the group, so bond strength and thermal stability decrease: $\mathrm{AsH}_{3}$ decomposes at $250^{\circ} \mathrm{C}, \mathrm{SbH}_{3}$ at $20^{\circ} \mathrm{C}$, and $\mathrm{BiH}_{3}$ at $-45^{\circ} \mathrm{C}$.
We'll see these features- H bonding for the smallest member, change in bond angles, change in bond energies - in the hydrides of Group $6 \mathrm{~A}(16)$ as well.

The Group $5 \mathrm{~A}(15)$ elements all form trihalides $\left(\mathrm{EX}_{3}\right)$. All except nitrogen form pentafluorides $\left(\mathrm{EF}_{5}\right)$, but only a few other pentahalides $\left(\mathrm{PCl}_{5}, \mathrm{PBr}_{5}, \mathrm{AsCl}_{5}\right.$, and $\mathrm{SbCl}_{5}$ ) are known. Nitrogen cannot form pentahalides because it cannot expand its valence shell. Most trihalides are prepared by direct combination:

$$
\mathrm{P}_{4}(s)+6 \mathrm{Cl}_{2}(g) \longrightarrow 4 \mathrm{PCl}_{3}(l)
$$

The pentahalides form with excess halogen:

$$
\mathrm{PCl}_{3}(l)+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{PCl}_{5}(s)
$$

As with the hydrides, the thermal stability of the halides decreases as the $\mathrm{E}-\mathrm{X}$ bond becomes longer. Among the nitrogen halides, for example, $\mathrm{NF}_{3}$ is a stable, rather unreactive gas. $\mathrm{NCl}_{3}$ is explosive and reacts rapidly with water. (The chemist who first prepared it lost three fingers and an eye!) $\mathrm{NBr}_{3}$ can only be made below $-87^{\circ} \mathrm{C}$. $\mathrm{NI}_{3}$ has never been prepared, but an ammoniated product $\left(\mathrm{NI}_{3} \cdot \mathrm{NH}_{3}\right)$ explodes at the slightest touch.

In an aqueous reaction pattern typical of many nonmetal halides, each 5A halide reacts with water to yield the hydrogen halide and the oxoacid, in which E has the same oxidation number as it had in the original halide. For example, $\mathrm{PX}_{5}(\mathrm{O} . \mathrm{N}$. of $\mathrm{P}=+5)$ produces phosphoric acid $(\mathrm{O} . \mathrm{N}$. of $\mathrm{P}=+5)$ and HX :

$$
\mathrm{PCl}_{5}(s)+4 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{PO}_{4}(l)+5 \mathrm{HCl}(g)
$$

## Highlights of Nitrogen Chemistry

Surely the most striking highlight of nitrogen chemistry is the inertness of $\mathrm{N}_{2}$ itself. Nearly four-fifths of the atmosphere consists of $\mathrm{N}_{2}$, and the other fifth is nearly all $\mathrm{O}_{2}$, a very strong oxidizing agent. Nevertheless, the searing temperature of a lightning bolt is required for significant amounts of atmospheric nitrogen oxides to form. Thus, even though $\mathrm{N}_{2}$ is inert at moderate temperatures, it reacts at high temperatures with $\mathrm{H}_{2}$, Li, Group $2 \mathrm{~A}(2)$ members, $\mathrm{B}, \mathrm{Al}, \mathrm{C}, \mathrm{Si}, \mathrm{Ge}$, $\mathrm{O}_{2}$, and many transition elements. In fact, nearly every element in the periodic table forms bonds to N . Here we focus on the oxides and the oxoacids and their salts.

Nitrogen Oxides Nitrogen is remarkable for having six stable oxides, each with a positive heat of formation because of the great strength of the $\mathrm{N} \equiv \mathrm{N}$ bond ( $\mathrm{BE}=945 \mathrm{~kJ} / \mathrm{mol}$ ). Their structures and some properties are shown in Table 14.3. Unlike the hydrides and halides of nitrogen, the oxides are planar. Nitrogen displays all its positive oxidation states in these compounds, and in $\mathrm{N}_{2} \mathrm{O}$ and $\mathrm{N}_{2} \mathrm{O}_{3}$, the two N atoms have different states.

Table 14.3 Structures and Properties of the Nitrogen Oxides

Nitrogen Monoxide: A Biochemical Surprise The tiny inorganic free radical NO is a remarkable player in an enormous range of biochemical systems. NO is biosynthesized in animal species from barnacles to humans. In the late 1980s and early 1990s, it was shown to play various roles in neurotransmission, blood clotting, blood pressure, and the destruction of cancer cells. The list of effects is now much longer and includes the harmful and beneficial ones of the NO-derived species $\mathrm{NO}_{2}, \mathrm{~N}_{2} \mathrm{O}_{3}, \mathrm{ONOO}^{-}$, and HNO. Living systems are full of surprises!

Figure 14.20 The formation of photochemical smog. Localized atmospheric concentrations of the precursor components of smog change during the day. In early morning traffic, exhaust from motor vehicles raises NO and hydrocarbon levels, followed by increases in $\mathrm{NO}_{2}$ as NO is oxidized by free radicals. Ozone peaks later, as $\mathrm{NO}_{2}$ breaks down in stronger sunlight and releases O atoms that react with $\mathrm{O}_{2}$. By midafternoon, all the components for the production of peroxyacylnitrates (PANs) are present, and photochemical smog results.

Dinitrogen monoxide $\left(\mathrm{N}_{2} \mathrm{O}\right.$; also called dinitrogen oxide or nitrous oxide) is the dental anesthetic "laughing gas" and the propellant in canned whipped cream. It is a linear molecule with an electronic structure best described by three resonance forms (note formal charges; see Problem 10.87):

Nitrogen monoxide ( NO ; also called nitrogen oxide or nitric oxide) is an oddelectron molecule with a vital biochemical function. In Section 11.3, we used MO theory to explain its bonding. The commercial preparation of NO through the oxidation of ammonia occurs as a first step in the production of nitric acid:

$$
4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)
$$

Nitrogen monoxide is also produced whenever air is heated to high temperatures, as in a car engine or a lightning storm:

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \xrightarrow{\operatorname{high} T} 2 \mathrm{NO}(g)
$$

Heating converts NO to two other oxides:

$$
3 \mathrm{NO}(g) \xrightarrow{\Delta} \mathrm{N}_{2} \mathrm{O}(g)+\mathrm{NO}_{2}(g)
$$

This type of redox reaction is called a disproportionation. It occurs when a substance acts as both an oxidizing and a reducing agent in a reaction. In the process, an atom with an intermediate oxidation state in the reactant occurs in the products in both lower and higher states: the oxidation state of N in $\mathrm{NO}(+2)$ is intermediate between that in $\mathrm{N}_{2} \mathrm{O}(+1)$ and that in $\mathrm{NO}_{2}(+4)$.

Nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$, a brown poisonous gas, forms to a small extent when NO reacts with additional oxygen:

Like $\mathrm{NO}, \mathrm{NO}_{2}$ is also an odd-electron molecule, but the electron is more localized on the N atom. Thus, $\mathrm{NO}_{2}$ dimerizes reversibly to dinitrogen tetraoxide:

$$
\mathrm{O}_{2} \mathrm{~N} \cdot(g)+\cdot \mathrm{NO}_{2}(g) \rightleftharpoons \mathrm{O}_{2} \mathrm{~N}-\mathrm{NO}_{2}(g) \quad\left(\text { or } \mathrm{N}_{2} \mathrm{O}_{4}\right)
$$

Thunderstorms form NO and $\mathrm{NO}_{2}$ and carry them down to the soil, where they act as natural fertilizers. In urban traffic, however, their formation leads to photochemical smog (Figure 14.20). During the morning commute, NO forms in car and truck (especially diesel) engines. It is then oxidized to $\mathrm{NO}_{2}$ by free radicals $\left(\mathrm{RO}_{2} \cdot\right)$, which form by oxidation of unburned hydrocarbons in gasoline fumes. As the Sun climbs later in the day, radiant energy breaks down some $\mathrm{NO}_{2}$ :

$$
\mathrm{NO}_{2}(g) \xrightarrow{\text { sunlight }} \mathrm{NO}(g)+\mathrm{O}(g)
$$

The O atoms collide with $\mathrm{O}_{2}$ molecules and form ozone, $\mathrm{O}_{3}$, a powerful oxidizing agent that damages synthetic rubber, plastics, and plant and animal tissue:

$$
\mathrm{O}_{2}(\mathrm{~g})+\mathrm{O}(\mathrm{~g}) \longrightarrow \mathrm{O}_{3}(\mathrm{~g})
$$

A complex series of reactions involving $\mathrm{NO}, \mathrm{NO}_{2}, \mathrm{O}_{3}$, unburned gasoline, and various free-radical species forms peroxyacylnitrates (PANs), a group of potent nose and eye irritants. The outcome of this fascinating atmospheric chemistry is choking, brown smog.

Nitrogen Oxoacids and Oxoanions The two common nitrogen oxoacids are nitric acid and nitrous acid (Figure 14.21). The first two steps in the Ostwald process for the production of nitric acid-the oxidations of $\mathrm{NH}_{3}$ to NO and of NO to $\mathrm{NO}_{2}$-have been shown. The final step is a disproportionation, as the oxidation numbers show:

$$
3 \stackrel{+4}{\mathrm{NO}_{2}}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \stackrel{+5}{2 \mathrm{HNO}_{3}(a q)}+\stackrel{+2}{\mathrm{NO}}(g)
$$

The NO is recycled to make more $\mathrm{NO}_{2}$.

Figure 14.21 The structures of nitric and nitrous acids and their oxoanions. A, Nitric acid loses a proton $\left(\mathrm{H}^{+}\right)$to form the trigonal planar nitrate ion (one of three resonance forms is shown). B, Nitrous acid, a much weaker acid, forms the planar nitrite ion (one of two resonance forms is shown). Note the effect of nitrogen's lone pair (the lone pairs of the oxygens are not shown) in reducing the ideal $120^{\circ}$ bond angle to $115^{\circ}$.

In nitric acid, as in all oxoacids, the acidic $H$ is attached to one of the $O$ atoms. In the laboratory, nitric acid is used as a strong oxidizing acid. The products of its reactions with metals vary with the metal's reactivity and the acid's concentration. In the following examples, notice from the net ionic equations that the $\mathrm{NO}_{3}{ }^{-}$ion is the oxidizing agentitaterion that mot reducd is spectaror ion and does not appear in the net ionic equations.

- With an active metal, such as Al , and dilute acid, N is reduced from the +5 state all the way to the -3 state in the ammonium ion, $\mathrm{NH}_{4}{ }^{+}$:

$$
8 \mathrm{Al}(s)+30 \mathrm{HNO}_{3}(a q ; 1 M) \longrightarrow 8 \mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}(a q)+3 \mathrm{NH}_{4} \mathrm{NO}_{3}(a q)+9 \mathrm{H}_{2} \mathrm{O}(l)
$$

$8 \mathrm{Al}(s)+30 \mathrm{H}^{+}(a q)+3 \mathrm{NO}_{3}^{-}(a q) \longrightarrow 8 \mathrm{Al}^{3+}(a q)+3 \mathrm{NH}_{4}{ }^{+}(a q)+9 \mathrm{H}_{2} \mathrm{O}(l)$

- With a less reactive metal, such as Cu , and more concentrated acid, N is reduced to the +2 state in NO:

$$
\begin{aligned}
& 3 \mathrm{Cu}(s)+8 \mathrm{HNO}_{3}(a q ; 3 \text { to } 6 M) \longrightarrow 3 \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{NO}(g) \\
& 3 \mathrm{Cu}(s)+8 \mathrm{H}^{+}(a q)+2 \mathrm{NO}_{3}^{-}(a q) \longrightarrow 3 \mathrm{Cu}^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{NO}(g)
\end{aligned}
$$

- With still more concentrated acid, N is reduced only to the +4 state in $\mathrm{NO}_{2}$ :

$$
\begin{gathered}
\mathrm{Cu}(s)+4 \mathrm{HNO}_{3}(a q ; 12 M) \longrightarrow \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{NO}_{2}(g) \\
\mathrm{Cu}(s)+4 \mathrm{H}^{+}(a q)+2 \mathrm{NO}_{3}^{-}(a q) \longrightarrow \mathrm{Cu}^{2+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{NO}_{2}(g)
\end{gathered}
$$

Nitrates form when $\mathrm{HNO}_{3}$ reacts with metals or with their hydroxides, oxides, or carbonates. All nitrates are soluble in water.

Nitrous acid, $\mathrm{HNO}_{2}$, a much weaker acid than $\mathrm{HNO}_{3}$, forms when metal nitrites are treated with a strong acid:

$$
\mathrm{NaNO}_{2}(a q)+\mathrm{HCl}(a q) \longrightarrow \mathrm{HNO}_{2}(a q)+\mathrm{NaCl}(a q)
$$

These two acids reveal a general pattern in relative acid strength among oxoacids: the more O atoms bonded to the central nonmetal, the stronger the acid. Thus, $\mathrm{HNO}_{3}$ is stronger than $\mathrm{HNO}_{2}$. The O atoms pull electron density from the N atom, which in turn pulls electron density from the O of the $\mathrm{O}-\mathrm{H}$ bond, facilitating the release of the $\mathrm{H}^{+}$ion. The O atoms also act to stabilize the resulting oxoanion by delocalizing its negative charge. The same pattern occurs in the oxoacids of sulfur and the halogens; we'll discuss the pattern quantitatively in Chapter 18.

Figure 14.22 Important oxides of phosphorus. $\mathrm{A}, \mathrm{P}_{4} \mathrm{O}_{6}$. $\mathrm{B}, \mathrm{P}_{4} \mathrm{O}_{10}$.

The Countless Uses of Phosphates Phosphates have an amazing array of applications in home and industry. $\mathrm{Na}_{3} \mathrm{PO}_{4}$ is a paint stripper and grease remover and is still used in cleaning powders in other countries. $\mathrm{Na}_{2} \mathrm{HPO}_{4}$ is a laxative ingredient and is used to adjust the acidity of boiler water. The potassium salt $\mathrm{K}_{3} \mathrm{PO}_{4}$ is used to stabilize latex for synthetic rubber, and $\mathrm{K}_{2} \mathrm{HPO}_{4}$ is a radiator corrosion inhibitor. Ammonium phosphates are used as fertilizers and as flame retardants on curtains and paper costumes. Calcium phosphates are used in baking powders and toothpastes, as mineral supplements in livestock feed, and (on the hundred-million-ton scale) as fertilizers throughout the world.

## Highlights of Phosphorus Chemistry: Oxides and Oxoacids

Phosphorus forms two important oxides, $\mathrm{P}_{4} \mathrm{O}_{6}$ and $\mathrm{P}_{4} \mathrm{O}_{10}$. Tetraphosphorus hexaoxide, $\mathrm{P}_{4} \mathrm{O}_{6}$, has P in its +3 oxidation state and forms when white $\mathrm{P}_{4}$ reacts with limited oxygen:

$$
\mathrm{P}_{4}(s)+3 \mathrm{O}_{2}(g) \longrightarrow \mathrm{P}_{4} \mathrm{O}_{6}(s)
$$

$\mathrm{P}_{4} \mathrm{O}_{6}$ has the tetrahedral orientation of the P atoms found in $\mathrm{P}_{4}$, with an O atom between each pair of P atoms (Figure 14.22A). It reacts with water to form phosphorous acid (note the spelling):

$$
\mathrm{P}_{4} \mathrm{O}_{6}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 4 \mathrm{H}_{3} \mathrm{PO}_{3}(l)
$$

The formula $\mathrm{H}_{3} \mathrm{PO}_{3}$ is misleading because the acid has only two acidic H atoms; the third is bonded to the central P and does not dissociate. Phosphorous acid is a weak acid in water but reacts completely in two steps with excess strong base:

Salts of phosphorous acid contain the phosphite ion, $\mathrm{HPO}_{3}{ }^{2-}$.
In tetraphosphorus decaoxide, $\mathrm{P}_{4} \mathrm{O}_{10}, \mathrm{P}$ is in the +5 oxidation state. Commonly known as "phosphorus pentoxide" from the empirical formula $\left(\mathrm{P}_{2} \mathrm{O}_{5}\right)$, it forms when $\mathrm{P}_{4}$ burns in excess $\mathrm{O}_{2}$ :

$$
\mathrm{P}_{4}(s)+5 \mathrm{O}_{2}(g) \longrightarrow \mathrm{P}_{4} \mathrm{O}_{10}(s)
$$

Its structure can be viewed as that of $\mathrm{P}_{4} \mathrm{O}_{6}$ with another O atom bonded to each of the four corner P atoms (Figure 14.22 B ). $\mathrm{P}_{4} \mathrm{O}_{10}$ is a powerful drying agent and, in a vigorous exothermic reaction with water, forms phosphoric acid $\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)$, one of the "top-90" most important compounds in chemical manufacturing:

$$
\mathrm{P}_{4} \mathrm{O}_{10}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 4 \mathrm{H}_{3} \mathrm{PO}_{4}(l)
$$

The presence of many H bonds makes pure $\mathrm{H}_{3} \mathrm{PO}_{4}$ syrupy, more than 75 times as viscous as water. The laboratory-grade concentrated acid is an $85 \%$ by mass aqueous solution. $\mathrm{H}_{3} \mathrm{PO}_{4}$ is a weak triprotic acid; in water, it loses one proton in the following equilibrium reaction:

$$
\mathrm{H}_{3} \mathrm{PO}_{4}(l)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)
$$

In excess strong base, however, the three protons dissociate completely in three steps to give the three phosphate oxoanions:

Phosphoric acid has a central role in fertilizer production, and it is also used as a polishing agent for aluminum car trim and as an additive in soft drinks to give a touch of tartness. The various phosphate salts have numerous essential applications.

Polyphosphates are formed by heating hydrogen phosphates, which lose water as they form $\mathrm{P}-\mathrm{O}-\mathrm{P}$ linkages. This type of reaction, in which an $\mathrm{H}_{2} \mathrm{O}$ molecule is lost for every pair of OH groups that join, is called a dehydrationcondensation; it occurs frequently in the formation of polyoxoanion chains and other polymeric structures, both synthetic and natural. For example, sodium diphosphate, $\mathrm{Na}_{4} \mathrm{P}_{2} \mathrm{O}_{7}$, is prepared by heating sodium hydrogen phosphate:

$$
2 \mathrm{Na}_{2} \mathrm{HPO}_{4}(s) \xrightarrow{\Delta} \mathrm{Na}_{4} \mathrm{P}_{2} \mathrm{O}_{7}(s)+\mathrm{H}_{2} \mathrm{O}(g)
$$

Figure 14.23 The diphosphate ion and polyphosphates. A, When two hydrogen phosphate ions undergo a dehydration-condensation reaction, they lose a water molecule and join through a shared O atom to form a diphosphate ion. B, Polyphosphates are chains of many such tetrahedral $\mathrm{PO}_{4}$ units. Chain shapes depend on the orientation of the individual units. Note the similarity to silicate chains (see the Gallery, p. 592).

The diphosphate ion, $\mathrm{P}_{2} \mathrm{O}_{7}{ }^{4-}$, the smallest of the polyphosphates, consists of two $\mathrm{PO}_{4}$ units linked through a common oxygen corner (Figure 14.23A). Its reaction with water, the reverse of the previous reaction, generates heat:

$$
\mathrm{P}_{2} \mathrm{O}_{7}^{4-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{HPO}_{4}^{-}(a q)+\text { heat }
$$

A similar process is put to vital use by organisms, when a third $\mathrm{PO}_{4}$ unit linked to diphosphate creates the triphosphate grouping, part of the all-important highenergy biomolecule adenosine triphosphate (ATP). In Chapters 20 and 21, we discuss the central role of ATP indielogical eneng prodaction. nExteded polyphosphate chains consist of many tetrahedral $\mathrm{PO}_{4}$ units (Figure 14.23B) and are structurally similar to silicate chains. As a final look at the chemical versatility of phosphorus, the margin note describes some of the numerous important compounds with sulfur and with nitrogen.

### 14.8 GROUP 6A(16): THE OXYGEN FAMILY

The first two members of this family-gaseous nonmetallic oxygen ( O ) and solid nonmetallic sulfur (S)—are among the most important elements in industry, the environment, and living things. Two metalloids, selenium ( Se ) and tellurium ( Te ), appear below them, then comes the lone metal, radioactive polonium ( Po ), and newly synthesized element 116 ends the group. The Group 6A(16) Family Portrait (pp. 604 and 605) displays the features of these elements.

## How Do the Oxygen and Nitrogen Families Compare Physically?

Group $6 \mathrm{~A}(16)$ resembles Group $5 \mathrm{~A}(15)$ in many respects, so let's look at some common themes. The pattern of physical properties we saw in Group 5A appears again in this group. Like nitrogen, oxygen occurs as a low-boiling diatomic gas. Like phosphorus, sulfur occurs as a polyatomic molecular solid. Like arsenic, selenium commonly occurs as a gray metalloid. Like antimony, tellurium is slightly more metallic than the preceding group member but still displays network covalent bonding. Finally, like bismuth, polonium has a metallic crystal structure. As we expect by comparison with the Group 5A elements, electrical conductivities increase steadily down Group 6A as bonding changes from individual molecules (insulators) to metalloid networks (semiconductors) to a metallic solid (conductor).

Match Heads, Bug Sprays, and O-Rings Phosphorus forms many sulfides and nitrides. $\mathrm{P}_{4} \mathrm{~S}_{3}$ is used in "strikeanywhere" match heads, and $\mathrm{P}_{4} \mathrm{~S}_{10}$ is used in the manufacture of organophosphorus pesticides, such as malathion. Polyphosphazenes have properties similar to those of silicones. Indeed, the $-\left(\mathrm{R}_{2}\right) \mathrm{P}=\mathrm{N}-$ unit is isoelectronic with the silicone unit, $-\left(\mathrm{R}_{2}\right) \mathrm{Si}-\mathrm{O}-$. Sheets, films, fibers, and foams of polyphosphazene are water repellent, flame resistant, solvent resistant, and flexible at low temperaturesperfect for the gaskets and O-rings in spacecraft and polar vehicles.

## Key Atomic and Physical Properties

## Some Reactions and Compounds

## Important Reactions

Halogenation and oxidation of the elements (E) appear in reactions 1 and 2 , and sulfur chemistry in reactions 3 and 4.

1. Halides are formed by direct combination:

$$
\begin{aligned}
\mathrm{E}(s)+\mathrm{X}_{2}(g) \longrightarrow & \text { various halides } \\
& (\mathrm{E}=\mathrm{S}, \mathrm{Se}, \mathrm{Te} ; \mathrm{X}=\mathrm{F}, \mathrm{Cl})
\end{aligned}
$$

2. The other elements in the group are oxidized by $\mathrm{O}_{2}$ :

$$
\mathrm{E}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{EO}_{2} \quad(\mathrm{E}=\mathrm{S}, \mathrm{Se}, \mathrm{Te}, \mathrm{Po})
$$

$\mathrm{SO}_{2}$ is oxidized further, and the product is used in the final step of $\mathrm{H}_{2} \mathrm{SO}_{4}$ manufacture (Highlights of Sulfur Chemistry):

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{SO}_{3}(g)
$$

3. Sulfur is recovered when hydrogen sulfide is oxidized:

$$
8 \mathrm{H}_{2} \mathrm{~S}(g)+4 \mathrm{O}_{2}(g) \longrightarrow \mathrm{S}_{8}(s)+8 \mathrm{H}_{2} \mathrm{O}(g)
$$

This reaction is used to obtain sulfur when natural deposits are not available.
4. The thiosulfate ion is formed when an alkali metal sulfite reacts with sulfur, as in the preparation of "hypo," photographer's developing solution:

$$
\mathrm{S}_{8}(s)+8 \mathrm{Na}_{2} \mathrm{SO}_{3}(a q) \longrightarrow 8 \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}(a q)
$$

## Important Compounds

1. Water, $\mathrm{H}_{2} \mathrm{O}$. The single most important compound on Earth (Section 12.5).
2. Hydrogen peroxide, $\mathrm{H}_{2} \mathrm{O}_{2}$. Used as an oxidizing agent, disinfectant, and bleach, and in the production of peroxy compounds for polymerization (margin note, p. 607).
3. Hydrogen sulfide, $\mathrm{H}_{2} \mathrm{~S}$. Vile-smelling toxic gas formed during anaerobic decomposition of plant and animal matter, in volcanoes, and in deep-sea thermal vents. Used as a source of sulfur and in the manufacture of paper. Atmospheric traces cause silver to tarnish through formation of black $\mathrm{Ag}_{2} \mathrm{~S}$ (see photo).
4. Sulfur trioxide $\left(\mathrm{SO}_{3}\right)$ and sulfuric acid $\left(\mathrm{H}_{2} \mathrm{SO}_{4}\right) . \mathrm{SO}_{3}$, formed from $\mathrm{SO}_{2}$ over a $\mathrm{K}_{2} \mathrm{O} / \mathrm{V}_{2} \mathrm{O}_{5}$ catalyst, is then converted to $\mathrm{H}_{2} \mathrm{SO}_{4}$. The acid is the cheapest strong acid and is so widely used in industry that its production level is an indicator of a nation's economic strength. It is a strong dehydrating agent that removes water from any organic source (Highlights of Sulfur Chemistry).
5. Sulfur hexafluoride, $\mathrm{SF}_{6}$. Extremely inert gas used as an electrical insulator.

Untarnished and tarnished silver spoons
4. Sulfur dioxide, $\mathrm{SO}_{2}$. Colorless, choking gas formed in volcanoes (see photo) or whenever an S-containing material (coal, oil, metal sulfide ores, and so on) is burned. More than $90 \%$ of $\mathrm{SO}_{2}$ produced is used to make sulfuric acid. Also used as a fumigant and a preservative of fruit, syrups, and wine. As a reducing agent, removes excess $\mathrm{Cl}_{2}$ from industrial wastewater, removes $\mathrm{O}_{2}$ from petroleum handling tanks, and prepares $\mathrm{ClO}_{2}$ for bleaching paper. Atmospheric pollutant in acid rain.

Allotropism is more common in Group $6 \mathrm{~A}(16)$ than in Group $5 \mathrm{~A}(15)$. Oxygen has two allotropes: life-giving dioxygen $\left(\mathrm{O}_{2}\right)$, and poisonous triatomic ozone $\left(\mathrm{O}_{3}\right)$. Oxygen gas is colorless, odorless, paramagnetic, and thermally stable. In contrast, ozone gas is bluish, has a pungent odor, is diamagnetic, and decomposes in heat and especially in ultraviolet (UV) light:

$$
2 \mathrm{O}_{3}(\mathrm{~g}) \xrightarrow{\mathrm{UV}} 3 \mathrm{O}_{2}(\mathrm{~g})
$$

This ability to absorb high-energy photons makes stratospheric ozone vital to life. A thinning of the ozone layer, observed above the North Pole and especially the South Pole, means that more UV light will reach Earth's surface, with potentially hazardous effects. (We'll discuss the chemical causes of ozone depletion in Chapter 16.)

Sulfur is the allotrope "champion" of the periodic table, with more than 10 forms. The S atom's ability to bond to other S atoms creates numerous rings and chains, with $\mathrm{S}-\mathrm{S}$ bond lengths that range from 180 pm to 260 pm and bond angles from $90^{\circ}$ to $180^{\circ}$. At room temperature, the sulfur molecule is a crownshaped ring of eight atoms, called cyclo- $S_{8}$ (Figure 14.24). The most stable allotrope is orthorhombic $\alpha-\mathrm{S}_{8}$, which consists entirely of these molecules; all other S allotropes eventually revert to this one.

Figind 14.24 Thecyclo- $\mathrm{S}_{8}$ molecule. A, Top view of a spacefilling model of the cyclo- $\mathrm{S}_{8}$ molecule. B, Side view of a ball-and-stick model of the molecule; note the crownlike shape.

Selenium also has several allotropes, some consisting of crown-shaped $\mathrm{Se}_{8}$ molecules. Gray Se is composed of layers of helical chains. Its electrical conductivity in visible light revolutionized the photocopying industry. - When molten glass, cadmium sulfide, and gray Se are mixed and heated in the absence of air, a ruby-red glass forms, which you see whenever you stop at a traffic light.

## How Do the Oxygen and Nitrogen Families Compare Chemically?

Changes in chemical behavior in Group $6 \mathrm{~A}(16)$ are also similar to those in the previous group. Even though O and S occur as anions much more often than do N and P , like N and P , they bond covalently with almost every other nonmetal. Covalent bonds appear in the compounds of Se and Te (as in those of As and Sb ), whereas Po behaves like a metal (as does Bi ) in some of its saltlike compounds. In contrast to nitrogen, oxygen has few common oxidation states, but the earlier pattern returns with the other members: the $+6,+4$, and -2 states occur most often, with the lower positive $(+4)$ state becoming more common in Te and Po [as the lower positive $(+3)$ state does in Sb and Bi].

The range in atomic properties is wider in this group than in Group $5 \mathrm{~A}(15)$ because of oxygen's high EN (3.5) and great oxidizing strength, second only to that of fluorine. As in 5A and earlier groups, the behavior of the Period 2 element stands out. In fact, aside from a similar outer electron configuration, the larger
members of Group 6A behave very little like oxygen: they are much less electronegative, form anions much less often ( $\mathrm{S}^{2-}$ occurs with active metals), and their hydrides exhibit no H bonding.

Except for O, all the 6A elements form foul-smelling, poisonous, gaseous hydrides $\left(\mathrm{H}_{2} \mathrm{E}\right)$ on treatment with acid of the metal sulfide, selenide, and so forth. For example,

$$
\mathrm{FeSe}(s)+2 \mathrm{HCl}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{Se}(g)+\mathrm{FeCl}_{2}(a q)
$$

Hydrogen sulfide also forms naturally in swamps from the breakdown of organic matter. It is as toxic as HCN, and even worse, it anesthetizes your olfactory nerves, so that as its concentration increases, you smell it less! The other hydrides are about 100 times more toxic.

In their bonding and thermal stability, these Group 6A hydrides have several features in common with those of Group 5A:

- Only water can form H bonds, so it melts and boils much higher than the other $\mathrm{H}_{2} \mathrm{E}$ compounds (see Figure 12.14, p. 453). (Oxygen's other hydride, $\mathrm{H}_{2} \mathrm{O}_{2}$, is also extensively H bonded.)
- Bond angles drop from the nearly tetrahedral value for $\mathrm{H}_{2} \mathrm{O}\left(104.5^{\circ}\right)$ to around $90^{\circ}$ for the larger 6 A hydrides, suggesting that the central atom uses unhybridized $p$ orbitals.
- $\mathrm{E}-\mathrm{H}$ bond length increases (bond energy decreases) down the group. Thus, $\mathrm{H}_{2} \mathrm{Te}$ decomposes above $0^{\circ} \mathrm{C}$, and $\mathrm{H}_{2} \mathrm{Po}$ can be made only in extreme cold because thermal energy from the radioactive Po decomposes it. Another result of longer (weaker) bonds is that the 6A hydrides are acids in water, and their acidity increases from $\mathrm{H}_{2} \mathrm{~S}$ to $\mathrm{H}_{2} \mathrm{Po}$.

Except for O, the Group 6A elements form a wide range of halides, whose
 surrounding halogens:

- Sulfur forms many fluorides, a few chlorides, one bromide, but no stable iodides.
- As the central atom becomes larger, the halides become more stable. Thus, tetrachlorides and tetrabromides of $\mathrm{Se}, \mathrm{Te}$, and Po are known, as are tetraiodides of Te and Po. Hexafluorides are known only for $\mathrm{S}, \mathrm{Se}$, and Te .

The inverse relationship between bond length and bond strength that we've seen previously does not account for this pattern. Rather, it is based on the effect of electron repulsions due to crowding of lone pairs and halogen $(\mathrm{X})$ atoms around the central Group 6A atom. With S, the larger X atoms would be too crowded, which explains why sulfur iodides do not occur. With increasing size of E , and therefore increasing length of $\mathrm{E}-\mathrm{X}$ bonds, however, lone pairs and X atoms do not crowd each other as much, and a greater number of stable halides form.

Two sulfur fluorides illustrate clearly how crowding and orbital availability affect reactivity. Sulfur tetrafluoride $\left(\mathrm{SF}_{4}\right)$ is extremely reactive. It forms $\mathrm{SO}_{2}$ and HF when exposed to moisture and is commonly used to fluorinate many compounds:

$$
3 \mathrm{SF}_{4}(g)+4 \mathrm{BCl}_{3}(g) \longrightarrow 4 \mathrm{BF}_{3}(g)+3 \mathrm{SCl}_{2}(l)+3 \mathrm{Cl}_{2}(g)
$$

In contrast, sulfur hexafluoride $\left(\mathrm{SF}_{6}\right)$ is almost as inert as a noble gas! It is odorless, tasteless, nonflammable, nontoxic, and insoluble. Hot metals, boiling HCl, molten KOH , and high-pressure steam have no effect on it. It is used as an insulating gas in high-voltage generators, withstanding over $10^{6}$ volts across electrodes only 50 mm apart. A look at the structures of these two fluorides provides

Hydrogen Peroxide: Hydrazine's Cousin In addition to water, oxygen forms another hydride, called hydrogen peroxide, $\mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{HO}-\mathrm{OH})$. Like hydrazine $\left(\mathrm{H}_{2} \mathrm{~N}-\mathrm{NH}_{2}\right)$, the related hydride of nitrogen, hydrogen peroxide has a skewed molecular shape. It is a colorless liquid with a high density, viscosity, and boiling point because of extensive H bonding. In peroxides, O has the -1 oxidation state, midway between that in $\mathrm{O}_{2}$ (zero) and that in oxides ( -2 ); thus, $\mathrm{H}_{2} \mathrm{O}_{2}$ readily disproportionates:

$$
\mathrm{H}_{2} \mathrm{O}_{2}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\frac{1}{2} \mathrm{O}_{2}(g)
$$

Aside from the familiar use of $\mathrm{H}_{2} \mathrm{O}_{2}$ as a hair bleach and disinfectant, more than $70 \%$ of the 0.5 million tons produced each year is used to bleach paper pulp, textiles, straw, and leather and to make other chemicals. $\mathrm{H}_{2} \mathrm{O}_{2}$ is also used in sewage treatment to oxidize bacteria.

Figure 14.25 Structural differences between $\mathrm{SF}_{4}$ and $\mathrm{SF}_{6}$. The S atom in $\mathrm{SF}_{4}$ has a lone pair and empty $d$ orbitals that can become involved in bonding. In $\mathrm{SF}_{6}$, the central $S$ atom already has the maximum number of bonds that it can form, and closely packed $F$ atoms envelop it, rendering $\mathrm{SF}_{6}$ chemically inert.

Acid from the Sky Awareness of $\mathrm{SO}_{2}$ as a major air pollutant has been widespread for years. Even though enormous amounts of $\mathrm{SO}_{2}$ form during volcanic and other geothermal activity, they are dwarfed by the amounts emitted from human sources: coal-burning power plants, petroleum refineries, and metal-ore smelters. In the atmosphere, $\mathrm{SO}_{2}$ undergoes several reaction steps to form sulfuric acid, which falls in rain, snow, and dust on animals, plants, buildings, and lakes (Chapter 19).
the key to these astounding differences (Figure 14.25). Sulfur in $\mathrm{SF}_{4}$ can form bonds to another atom either by donating its lone electron pair or by accepting a lone pair into one of its empty $d$ orbitals. On the other hand, the central S atom in $\mathrm{SF}_{6}$ has no lone pair, and the six F atoms around it form an octahedral sheath that blocks chemical attack.

## Highlights of Oxygen Chemistry: Range of Oxide Properties

Oxygen is the most abundant element on Earth's surface, occurring both as the free element and in innumerable oxides, silicates, carbonates, and phosphates, as well as in water. Virtually all free $\mathrm{O}_{2}$ has a biological origin, having been formed for billions of years by photosynthetic algae and multicellular plants in an overall equation that looks deceptively simple:

$$
n \mathrm{H}_{2} \mathrm{O}(l)+n \mathrm{CO}_{2}(g) \xrightarrow{\text { light }} n \mathrm{O}_{2}(g)+\left(\mathrm{CH}_{2} \mathrm{O}\right)_{n} \text { (carbohydrates) }
$$

The reverse process occurs during combustion and respiration. Through these $\mathrm{O}_{2}{ }^{-}$ forming and $\mathrm{O}_{2}$-utilizing processes, the $1.5 \times 10^{9} \mathrm{~km}^{3}$ of water on Earth is, on average, used and remade every 2 million years!

Every element (except $\mathrm{He}, \mathrm{Ne}$, and Ar ) forms at least one oxide, many by direct combination. A broad spectrum of properties characterizes these compounds. Some oxides are gases that condense at very low temperatures, such as $\mathrm{CO}\left(\mathrm{bp}=-192^{\circ} \mathrm{C}\right)$; others are solids that melt at extremely high temperatures, such as $\mathrm{BeO}\left(\mathrm{mp}=2530^{\circ} \mathrm{C}\right)$. Oxides cover the full range of conductivity: insulators $(\mathrm{MgO})$, semiconductors $(\mathrm{NiO})$, conductors $\left(\mathrm{ReO}_{3}\right)$, and superconductors $\left(\mathrm{YBa}_{2} \mathrm{Cu}_{3} \mathrm{O}_{7}\right)$. Some oxides have endothermic heats of formation $\left(\Delta H_{\mathrm{f}}^{\circ}\right.$ of $\mathrm{NO}=$ $+90.3 \mathrm{~kJ} / \mathrm{mol})$, whereas other oxides have exothermic ones $\left(\Delta H_{\mathrm{f}}^{\circ}\right.$ of $\mathrm{CO}_{2}=$ $-393.5 \mathrm{~kJ} / \mathrm{mol})$. They may be thermally stable $(\mathrm{CaO})$ or unstable $(\mathrm{HgO})$, as well as_chemically reactive $\left(\mathrm{Li}_{2} 9\right)$ or inert $\left(\mathrm{Fe}_{2} \mathrm{O}_{3}\right)$.
Aquve this vast range of betavior, another useful way to classify element oxides is by their acid-base properties (see Interchapter, Topic 4). The oxides of Group $6 \mathrm{~A}(16)$ exhibit expected trends in acidity, with $\mathrm{SO}_{3}$ the most acidic and $\mathrm{PoO}_{2}$ the most basic.

## Highlights of Sulfur Chemistry: Oxides, Oxoacids, and Sulfides

Like phosphorus, sulfur forms two important oxides, sulfur dioxide $\left(\mathrm{SO}_{2}\right)$ and sulfur trioxide $\left(\mathrm{SO}_{3}\right)$. Sulfur is in its +4 oxidation state in $\mathrm{SO}_{2}$, a colorless, choking gas that forms whenever $\mathrm{S}, \mathrm{H}_{2} \mathrm{~S}$, or a metal sulfide burns in air:

$$
\begin{aligned}
& 2 \mathrm{H}_{2} \mathrm{~S}(g)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(g)+2 \mathrm{SO}_{2}(g) \\
& 4 \mathrm{FeS}_{2}(s)+11 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Fe}_{2} \mathrm{O}_{3}(s)+8 \mathrm{SO}_{2}(g)
\end{aligned}
$$

Most $\mathrm{SO}_{2}$ is used to produce sulfuric acid.
In water, sulfur dioxide forms sulfurous acid, which exists in equilibrium with hydrated $\mathrm{SO}_{2}$ rather than as isolable $\mathrm{H}_{2} \mathrm{SO}_{3}$ molecules:

$$
\mathrm{SO}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons\left[\mathrm{H}_{2} \mathrm{SO}_{3}(a q)\right] \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{HSO}_{3}^{-}(a q)
$$

(Similarly, carbonic acid occurs in equilibrium with hydrated $\mathrm{CO}_{2}$ and cannot be isolated as $\mathrm{H}_{2} \mathrm{CO}_{3}$ molecules.) Sulfurous acid is weak and has two acidic protons, forming the hydrogen sulfite (bisulfite, $\mathrm{HSO}_{3}{ }^{-}$) and sulfite $\left(\mathrm{SO}_{3}{ }^{2-}\right)$ ions with strong base. Because the S in $\mathrm{SO}_{3}{ }^{2-}$ is in the +4 state and is easily oxidized to the +6 state, sulfites are good reducing agents and are used to preserve foods and wine by eliminating undesirable products of air oxidation.

En route to sulfuric acid, $\mathrm{SO}_{2}$ is first oxidized to $\mathrm{SO}_{3}$ ( S in the +6 state) by heating in $\mathrm{O}_{2}$ over a catalyst:

$$
\mathrm{SO}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \xlongequal{\mathrm{V}_{2} \mathrm{O}_{5} / \mathrm{K}_{2} \mathrm{O} \text { catalyst }} \mathrm{SO}_{3}(g)
$$

Figure 14.26 The dehydration of carbohydrates by sulfuric acid. The protons of concentrated $\mathrm{H}_{2} \mathrm{SO}_{4}$ combine exothermically with water, dehydrating many organic materials. When table sugar is treated with sulfuric acid, the components of water are removed from the carbohydrate molecules $\left(\mathrm{CH}_{2} \mathrm{O}\right)_{n}$. Steam forms, and the remaining carbon expands to a porous mass.
(We discuss how catalysts work in Chapter 16 and how $\mathrm{H}_{2} \mathrm{SO}_{4}$ is produced in Chapter 22.) The $\mathrm{SO}_{3}$ is absorbed into concentrated $\mathrm{H}_{2} \mathrm{SO}_{4}$ and treated with additional $\mathrm{H}_{2} \mathrm{O}$ :

$$
\mathrm{SO}_{3}\left(\text { in concentrated } \mathrm{H}_{2} \mathrm{SO}_{4}\right)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(l)
$$

With more than 40 million tons produced each year in the United States alone, $\mathrm{H}_{2} \mathrm{SO}_{4}$ ranks first among all industrial chemicals. Fertilizer production, metal, pigment, and textile processing, and soap and detergent manufacturing are just a few of the major industries that depend on sulfuric acid.

Concentrated laboratory-grade sulfuric acid is a viscous, colorless liquid that is $98 \% \mathrm{H}_{2} \mathrm{SO}_{4}$ by mass. Like other strong acids, $\mathrm{H}_{2} \mathrm{SO}_{4}$ dissociates completely in water, forming the hydrogen sulfate (or bisulfate) ion, a much weaker acid:

Most common hydrogen sulfates and sulfates are water soluble, but those of Group $2 \mathrm{~A}(2)$ members (except $\mathrm{MgSO}_{4}$ ), $\mathrm{Pb}^{2+}$, and $\mathrm{Hg}_{2}{ }^{2+}$ are not.

Concentrated sulfuric acid is an excellent dehydrating agent. Its loosely held proton transfers to water in a highly exothermic formation of hydronium $\left(\mathrm{H}_{3} \mathrm{O}^{+}\right)$ ions. This process can occur even when the reacting substance contains no free water. For example, $\mathrm{H}_{2} \mathrm{SO}_{4}$ dehydrates wood, natural fibers, and many other organic substances by removing the components of water from the molecular structure, leaving behind a carbonaceous mass (Figure 14.26).

Thiosulfuric acid $\left(\mathrm{H}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}\right)$ is a structural analog of sulfuric acid in which a second S substitutes for one of the O atoms (thio- means "containing sulfur in place of oxygen"). The thiosulfate ion $\left(\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}\right)$ is an important reducing agent in chemical analysis. However, its largest commercial use is in photography, where sodium thiosulfate pentahydrate $\left(\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3} \cdot 5 \mathrm{H}_{2} \mathrm{O}\right)$, known as "hypo," is involved in fixing the image (Section 23.3).

Many metals combine directly with S to form metal sulfides. Indeed, naturally occurring sulfides are ores, which are mined for the extraction of many metals, including copper, zinc, lead, and silver. Aside from the sulfides of Groups $1 \mathrm{~A}(1)$ and $2 \mathrm{~A}(2)$, most metal sulfides do not have discrete $\mathrm{S}^{2-}$ ions. Several transition metals, such as chromium, iron, and nickel, form covalent, alloy-like, nonstoichiometric compounds with S , such as $\mathrm{Cr}_{0.88} \mathrm{~S}$ or $\mathrm{Fe}_{0.86} \mathrm{~S}$. Some important minerals contain $\mathrm{S}_{2}{ }^{2-}$ ions; an example is iron pyrite, or "fool's gold" $\left(\mathrm{FeS}_{2}\right)$ (Figure 14.27). We discuss the metallurgy of ores in Chapter 22.

Figure 14.27 A common sulfide
mineral. Pyrite ( $\mathrm{FeS}_{2}$ ), or fool's gold, is a beautiful but relatively cheap mineral that contains the $\mathrm{S}_{2}{ }^{2-}$ ion, but no gold.

Figure 14.28 Standing in Group 6A(16), looking backward to Group 5A(15) and forward to Group 7A(17).

## Looking Backward and Forward: Groups 5A(15), 6A(16), and 7A(17)

Groups $5 \mathrm{~A}(15)$ and $6 \mathrm{~A}(16)$ are very similar in their physical and chemical trends and in the versatility of phosphorus and sulfur (Figure 14.28). Their greatest difference is the sluggish behavior of $\mathrm{N}_{2}$ compared with the striking reactivity of $\mathrm{O}_{2}$. In both groups, metallic character appears only in the largest members. From here on, metals and even metalloids are left behind: all Group 7A(17) elements are reactive nonmetals. Anion formation, which was rare in 5A and more common in 6A, is one of the dominant features of 7A. Another feature of the 7A elements is the number of covalent compounds they form with oxygen and with each other.

### 14.9 GROUP 7A(17): THE HALOGENS

Our last chance to view elements of great reactivity occurs in Group 7A(17). The halogens begin with fluorine (F), the strongest electron "grabber" of all. Chlorine $(\mathrm{Cl})$, bromine $(\mathrm{Br})$, and iodine (I) also form compounds with most elements, and even extremely rare astatine (At) is thought to be reactive. The key features of Group 7A(17) are presented in the Family Portrait on pages 612 and 613.

## What Accounts for the Regular Changes in the Halogens' Physical Properties?

Like the alkali metals at the other end of the periodic table, the halogens display regular trends in their physical properties. However, whereas melting and boiling points and heats of fusion and vaporization decrease down Group 1A(1), these properties increase down Group 7A(17) (see the Interchapter, Topic 6). The reason for these opposite trend iphe Tifferenthpegi bonding in the elements. The alkali metals consist of atoms held together by metallic bonding, which decreases in strength as the atoms become larger. The halogens, on the other hand, exist as diatomic molecules that interact through dispersion forces, which increase in strength as the atoms become larger and more easily polarized. Thus, $\mathrm{F}_{2}$ is a very pale yellow gas, $\mathrm{Cl}_{2}$ a yellow-green gas, $\mathrm{Br}_{2}$ a brown-orange liquid, and $\mathrm{I}_{2}$ a purple-black solid.

## Why Are the Halogens So Reactive?

The Group 7A(17) elements react with most metals and nonmetals to form many ionic and covalent compounds: metal and nonmetal halides, halogen oxides, and oxoacids. The reason for halogen reactivity is the same as that for alkali metal reactivity -an electron configuration one electron away from that of a noble gas. Whereas a 1 A metal atom must lose one electron to attain a filled outer level, $a$ 7 A nonmetal atom must gain one electron to fill its outer level. It accomplishes this filling in either of two ways:

1. Gaining an electron from a metal atom, thus forming a negative ion as the metal forms a positive one
2. Sharing an electron pair with a nonmetal atom, thus forming a covalent bond

Down the group, reactivity reflects the decrease in electronegativity: $\mathrm{F}_{2}$ is the most reactive and $I_{2}$ the least. The exceptional reactivity of elemental $F_{2}$ is also related to the weakness of the $\mathrm{F}-\mathrm{F}$ bond. Because F is small, the bond is short; however, the lone pairs on each F atom repel those on the other, which weakens the bond (Figure 14.29). As a result of these factors, $\mathrm{F}_{2}$ reacts with every element (except $\mathrm{He}, \mathrm{Ne}$, and Ar ), in many cases, explosively.

The halogens display the largest range in electronegativity of any group, but all are electronegative enough to behave as nonmetals. They act as oxidizing

Figure 14.29 Bond energies and bond lengths of the halogens. A, In keeping with the increase in atomic size down the group, bond lengths increase steadily. B, The halogens show a general decrease in bond energy as bond length increases. However, $F_{2}$ deviates from this trend because its small, close, electron-rich atoms repel each other, thereby lowering its bond energy.
agents in the majority of their reactions, and halogens higher in the group can oxidize halide ions lower down:

$$
\mathrm{F}_{2}(g)+2 \mathrm{X}^{-}(a q) \longrightarrow 2 \mathrm{~F}^{-}(a q)+\mathrm{X}_{2}(a q) \quad(\mathrm{X}=\mathrm{Cl}, \mathrm{Br}, \mathrm{I})
$$

Thus, the oxidizing ability of $\mathrm{X}_{2}$ decreases down the group: the lower the EN, the less strongly each $X$ atom pulls electrons. Similarly, the reducing ability of $\mathrm{X}^{-}$increases down the group: the larger the ion, the more easily it gives up its electron (Figure 14.30).

The halogens undergo some important aqueous redox chemistry. Fluorine is such a powerful oxidizing agent that it tears water apart, oxidizing the O to produce $\mathrm{O}_{2}$, some $\mathrm{O}_{3}$, and HFO (hypofluorous acid). The other halogens undergo disproportionations (note the oxidation numbers):

At equilibrium, very little product is present unless excess $\mathrm{OH}^{-}$ion is added, which reacts with the HX and HXO and drives the reaction to completion:

$$
\mathrm{X}_{2}+2 \mathrm{OH}^{-}(a q) \longrightarrow \mathrm{X}^{-}(a q)+\mathrm{XO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

When X is Cl , the product mixture acts as a bleach: household bleach is a dilute solution of sodium hypochlorite $(\mathrm{NaClO})$. Heating causes $\mathrm{XO}^{-}$to disproportionate further, creating oxoanions with X in a higher oxidation state:

$$
3 \stackrel{+1}{\mathrm{XO}^{-}}(a q) \xrightarrow{\Delta} 2 \stackrel{-1}{\mathrm{X}}^{-}(a q)+\stackrel{+5}{\mathrm{XO}_{3}}{ }^{-}(a q)
$$

Figure 14.30 The relative oxidizing ability of the halogens. A, Halogen redox behavior is based on atomic properties such as electron affinity, ionic charge density, and electronegativity. A halogen $\left(\mathrm{X}_{2}\right)$ higher in the group can oxidize a halide ion $\left(\mathrm{X}^{-}\right)$lower down. B , As an example, when aqueous $\mathrm{Cl}_{2}$ is added to a solution of $\mathrm{I}^{-}$(top layer), it oxidizes the $\mathrm{I}^{-}$to $\mathrm{I}_{2}$, which dissolves in the $\mathrm{CCl}_{4}$ solvent (bottom layer) to give a purple solution.

Key Atomic and Physical Properties

## Some Reactions and Compounds

## Important Reactions

Oxidizing strength and aqueous redox chemistry of the halogens are shown in reactions 1 and 2 , and industrial processes involving fluorine in reactions 3 and 4.

1. The halogens $\left(\mathrm{X}_{2}\right)$ oxidize many metals and nonmetals. The reaction with hydrogen, although not used commercially for HX production (except for high-purity HCl ), is characteristic of these strong oxidizing agents:

$$
\mathrm{X}_{2}+\mathrm{H}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{HX}(\mathrm{~g})
$$

2. The halogens disproportionate in water:

$$
\begin{array}{r}
\mathrm{X}_{2}+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HX}(a q)+\mathrm{HXO}(a q) \\
\\
(\mathrm{X}=\mathrm{Cl}, \mathrm{Br}, \mathrm{I})
\end{array}
$$

In aqueous base, the reaction goes to completion to form hypohalites (see text) and, at higher temperatures, halates; for example:

$$
3 \mathrm{Cl}_{2}(g)+6 \mathrm{OH}^{-}(a q) \xrightarrow{\Delta} \mathrm{ClO}_{3}^{-}(a q)+5 \mathrm{Cl}^{-}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l)
$$

## Important Compounds

1. Fluorspar (fluorite), $\mathrm{CaF}_{2}$. Widely distributed mineral used as a flux in steelmaking and in the production of HF (see photo).
2. Hydrogen fluoride, HF. Colorless, extremely toxic gas used to make $\mathrm{F}_{2}$, organic fluorine compounds, and polymers. Also used in aluminum manufacture and in glass etching (margin note, p. 614).

Fluorite
3. Hydrogen chloride, HCl . Extremely water-soluble gas that forms hydrochloric acid, which occurs naturally in the stomach fluids of mammals (humans produce 1.5 L of 0.1 M HCl daily) and in volcanic gases (from reaction of $\mathrm{H}_{2} \mathrm{O}$ and sea salt). Made by reaction of NaCl and $\mathrm{H}_{2} \mathrm{SO}_{4}$ and as a byproduct of plastics (PVC) production. Used in the "pickling" of steel (removal of adhering oxides) and in the production of syrups, rayon, and plastic.
4. Sodium hypochlorite, NaClO , and calcium hypochlorite, $\mathrm{Ca}(\mathrm{ClO})_{2}$. Oxidizing agents used to bleach wood pulp and textiles and to disinfect swimming pools, foods, and sewage (also used to disinfect the Apollo 11 on return from the Moon). Household bleach is $5.25 \% \mathrm{NaClO}$ by mass in water.
5. Ammonium perchlorate, $\mathrm{NH}_{4} \mathrm{ClO}_{4}$. Strong oxidizing agent used in the space shuttle program (see photo).
3. $\mathrm{F}_{2}$ is produced electrolytically at moderate temperature:

2 HF (as a soln of KF in HF) $\xrightarrow[90^{\circ} \mathrm{C}]{\text { electrolysis }} \mathrm{H}_{2}(\mathrm{~g})+\mathrm{F}_{2}(\mathrm{~g})$
A major use of $\mathrm{F}_{2}$ is in the preparation of $\mathrm{UF}_{6}$ for nuclear fuel.
4. Glass (amorphous silica) is etched with HF:

$$
\mathrm{SiO}_{2}(s)+6 \mathrm{HF}(g) \longrightarrow \mathrm{H}_{2} \mathrm{SiF}_{6}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

Space shuttle
6. Potassium iodide, KI. Most common soluble iodide. Added to table salt to prevent thyroid disease (goiter). Used in chemical analysis because it is easily oxidized to $\mathrm{I}_{2}$, which provides a colored end point.
7. Polychlorinated biphenyls, PCBs. Mixture of chlorinated organic compounds used as nonflammable insulating liquids in electrical transformers. Production discontinued because of persistence in the environment, where they become concentrated in the tissues of fish, birds, and mammals, and cause reproductive disturbances and possibly cancer.

HF: Unusual Structure, Familiar Uses At room temperature, all the hydrogen halides except HF are diatomic gases. As a result of its extensive H bonding, gaseous HF exists as short chains or rings of formula $(\mathrm{HF})_{6}$; liquid HF boils at $19.5^{\circ} \mathrm{C}$, more than 50 degrees higher than even the much heavier HI; and solid HF exists as an H-bonded polymer. HF has many uses, including the synthesis of cryolite $\left(\mathrm{Na}_{3} \mathrm{AlF}_{6}\right)$ for aluminum production, of fluorocarbons for refrigeration, and of NaF for water fluoridation. HF is also used in nuclear fuel processing and for glass etching in the manufacture of lightbulbs, transistors, and TV tubes.

## Highlights of Halogen Chemistry

In this section, we examine the compounds the halogens form with hydrogen and with each other, as well as their oxides, oxoanions, and oxoacids.
The Hydrogen Halides The halogens form gaseous hydrogen halides (HX) through direct combination with $\mathrm{H}_{2}$ or through the action of a concentrated acid on the metal halide (a nonoxidizing acid is used for HBr and HI ):

$$
\begin{gathered}
\mathrm{CaF}_{2}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(l) \longrightarrow \mathrm{CaSO}_{4}(s)+2 \mathrm{HF}(g) \\
3 \mathrm{NaBr}(s)+\mathrm{H}_{3} \mathrm{PO}_{4}(l) \longrightarrow \mathrm{Na}_{3} \mathrm{PO}_{4}(s)+3 \mathrm{HBr}(g)
\end{gathered}
$$

Commercially, most HCl is formed as a byproduct in the chlorination of hydrocarbons for plastics production:

$$
\mathrm{CH}_{2}=\mathrm{CH}_{2}(g)+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{ClCH}_{2} \mathrm{CH}_{2} \mathrm{Cl}(l) \xrightarrow{500^{\circ} \mathrm{C}} \mathrm{CH}_{2}=\mathrm{CHCl}(g)+\mathrm{HCl}(g)
$$

In this case, the vinyl chloride reacts in a separate process to form poly(vinyl chloride), or PVC, a polymer used extensively in modern plumbing pipes.

In water, gaseous HX molecules form a hydrohalic acid. Only HF, with its relatively short, strong bond, forms a weak acid:

$$
\mathrm{HF}(g)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{F}^{-}(a q)
$$

The others dissociate completely to form the stoichiometric amount of $\mathrm{H}_{3} \mathrm{O}^{+}$ions:

$$
\mathrm{HBr}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{Br}^{-}(a q)
$$

(We saw reactions similar to these in Chapter 4. They involve transfer of a proton from acid to $\mathrm{H}_{2} \mathrm{O}$ and are classified as Brønsted-Lowry acid-base reactions. In Chapter 18, we discuss them thoroughly and examine the relation between bond length and acidity of the larger HX molecules.)
Interhalogen Compoundsernerfatogen Halides" Halogens react exothermically with one another to form many interhalogen compounds. The simplest are diatomic molecules, such as CIF or BrCl . Every binary combination of the four common halogens is known. The more electronegative halogen is in the -1 oxidation state, and the less electronegative is in the +1 state. It has been proposed that interhalogens of general formula $\mathrm{XY}_{n}(n=3,5,7)$ form when the larger members of the group ( X ) use $d$ orbitals to expand their valence shells. In every case, the central atom has the lower electronegativity and a positive oxidation state.

The commercially useful interhalogens are powerful fluorinating agents, some of which react with metals, nonmetals, and oxides-even wood and asbestos:

$$
\begin{aligned}
\mathrm{Sn}(s)+\mathrm{ClF}_{3}(l) & \longrightarrow \mathrm{SnF}_{2}(s)+\mathrm{ClF}(g) \\
\mathrm{P}_{4}(s)+5 \mathrm{ClF}_{3}(l) & \longrightarrow 4 \mathrm{PF}_{3}(g)+3 \mathrm{ClF}(g)+\mathrm{Cl}_{2}(g) \\
2 \mathrm{~B}_{2} \mathrm{O}_{3}(s)+4 \mathrm{BrF}_{3}(l) & \longrightarrow 4 \mathrm{BF}_{3}(g)+2 \mathrm{Br}_{2}(l)+3 \mathrm{O}_{2}(g)
\end{aligned}
$$

Their reactions with water are nearly explosive and yield HF and the oxoacid in which the central halogen has the same oxidation state. For example,

$$
3 \mathrm{H}_{2} \mathrm{O}(l)+\stackrel{+5}{\mathrm{BrF}_{5}}(l) \longrightarrow 5 \mathrm{HF}(g)+\stackrel{+5}{\mathrm{HBrO}_{3}(a q)}
$$

The Oddness and Evenness of Oxidation States In Topic 5 of the Interchapter, we saw that odd-numbered groups exhibit odd-numbered oxidation states and even-numbered groups exhibit even-numbered states. The reason for this general behavior is that almost all stable molecules have paired electrons, either as bonding or lone pairs. Therefore, when bonds form or break, two electrons are involved, so the oxidation state changes by 2.

Consider the interhalogens. Four general formulas are $\mathrm{XY}, \mathrm{XY}_{3}, \mathrm{XY}_{5}$, and $\mathrm{XY}_{7}$; examples are shown in Figure 14.31. With Y in the -1 state, X must be in the $+1,+3,+5$, and +7 state, respectively. The -1 state arises when Y fills its valence level; the +7 state arises when the central halogen $(\mathrm{X})$ is completely

## CIF

Figure 14.31 Molecular shapes of the main types of interhalogen compounds.
oxidized, that is, when all seven valence electrons have shifted away from it to the more electronegative Y atoms around it.

Let's examine the iodine fluorides to see why the oxidation states jump by two units. When $\mathrm{I}_{2}$ reacts with $\mathrm{F}_{2}$, IF forms (note the oxidation number of I):

$$
\mathrm{I}_{2}+\mathrm{F}_{2} \longrightarrow \stackrel{+1}{2 \mathrm{IF}}
$$

In $\mathrm{IF}_{3}$, I uses two more valence electrons to form two more bonds:

$$
\stackrel{+1}{\mathrm{IF}}+\mathrm{F}_{2} \longrightarrow \stackrel{+3}{\mathrm{IF}_{3}}
$$

Otherwise, an unstable lone-electron species containing two fluorines would form. With more fluorine, another jump of two units occurs and the pentafluoride forms:

$$
{ }^{+3} \mathrm{IF}_{3}+\mathrm{F}_{2} \longrightarrow \stackrel{+5}{\mathrm{IF}_{5}}
$$

With still more fluorine, the heptafluoride forms:

## 

An element in an even-numbered group, such as sulfur in Group 6A(16), shows the same tendency for its compounds to have paired electrons. Elemental sulfur (oxidation number, O.N. $=0$ ) gains or shares two electrons to complete its shell (O.N. $=-2$ ). It uses two electrons to react with fluorine, for example, and form $\mathrm{SF}_{2}(\mathrm{O} . \mathrm{N} .=+2)$, two more electrons for $\mathrm{SF}_{4}(\mathrm{O} . \mathrm{N} .=+4)$, and two more for $\mathrm{SF}_{6}(\mathrm{O} . \mathrm{N} .=+6)$. Thus, an element with one even state typically has all even states, and an element with one odd state typically has all odd states. To reiterate the main point, successive oxidation states differ by two units because stable molecules have electrons in pairs around their atoms.
Halogen Oxides, Oxoacids, and Oxoanions The Group 7A(17) elements form many oxides that are powerful oxidizing agents and acids in water. Dichlorine monoxide $\left(\mathrm{Cl}_{2} \mathrm{O}\right)$ and especially chlorine dioxide $\left(\mathrm{ClO}_{2}\right)$ are used to bleach paper (Figure 14.32). $\mathrm{ClO}_{2}$ is unstable to heat and shock, so it is prepared on site, and more than 100,000 tons are used annually:

$$
2 \mathrm{NaClO}_{3}(s)+\mathrm{SO}_{2}(g)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow 2 \mathrm{ClO}_{2}(g)+2 \mathrm{NaHSO}_{4}(a q)
$$

The dioxide has an unpaired electron and Cl in the unusual +4 oxidation state.

Lone $\mathrm{e}^{-}$

Chlorine dioxide $\left(\mathrm{ClO}_{2}\right)$

Dichlorine heptaoxide $\left(\mathrm{Cl}_{2} \mathrm{O}_{7}\right)$

Figure 14.32 Chlorine oxides.
Dichlorine monoxide and chlorine dioxide are bent molecules; note the lone electron in $\mathrm{ClO}_{2}$. Dichlorine heptaoxide can be viewed as two $\mathrm{ClO}_{4}$ tetrahedra joined through an O corner. (Each ball-and-stick model shows the structure in which each atom has its lowest formal charge. Lone pairs are shown on the central atoms only.)
 of tons of perchlorates are made each year for use in explosives and fireworks. The white flash of a fireworks display is caused by $\mathrm{KClO}_{4}$ reacting with powdered sulfur and aluminum. At rock concerts and other theatrical productions, mixtures of $\mathrm{KClO}_{4}$ and Mg are often used for special effects.

Chlorine is in its highest $(+7)$ oxidation state in dichlorine heptaoxide, $\mathrm{Cl}_{2} \mathrm{O}_{7}$, which is a symmetrical molecule formed when two $\mathrm{HClO}_{4}\left(\mathrm{HO}-\mathrm{ClO}_{3}\right)$ molecules undergo a dehydration-condensation reaction:

$$
\mathrm{O}_{3} \mathrm{Cl}-\mathrm{OH}+\mathrm{HO}-\mathrm{ClO}_{3} \longrightarrow \mathrm{O}_{3} \mathrm{Cl}-\mathrm{O}-\mathrm{ClO}_{3}(l)+\mathrm{H}_{2} \mathrm{O}(l)
$$

The halogen oxoacids and oxoanions are produced by reaction of the halogens and their oxides with water. Most of the oxoacids are stable only in solution. Table 14.4 shows ball-and-stick models of the acids in which each atom has its lowest formal charge; note the formulas, which emphasize that H is bonded to O. The hypohalites $\left(\mathrm{XO}^{-}\right)$, halites $\left(\mathrm{XO}_{2}{ }^{-}\right)$, and halates $\left(\mathrm{XO}_{3}{ }^{-}\right)$are oxidizing agents formed by aqueous disproportionation reactions [see the Group 7A(17) Family Portrait, reaction 2]. You may have heated solid alkali chlorates in the laboratory to form small amounts of $\mathrm{O}_{2}$ :

$$
2 \mathrm{MClO}_{3}(s) \xrightarrow{\Delta} 2 \mathrm{MCl}(s)+3 \mathrm{O}_{2}(g)
$$

Potassium chlorate is the oxidizer in "safety" matches.
Several perhalates are also strong oxidizing agents. Ammonium perchlorate, prepared from sodium perchlorate, is the oxidizing agent for the aluminum powder in the solid-fuel booster rockets of space shuttles; each launch uses more than 700 tons of $\mathrm{NH}_{4} \mathrm{ClO}_{4}$ :

$$
10 \mathrm{Al}(s)+6 \mathrm{NH}_{4} \mathrm{ClO}_{4}(s) \longrightarrow 4 \mathrm{Al}_{2} \mathrm{O}_{3}(s)+12 \mathrm{H}_{2} \mathrm{O}(g)+3 \mathrm{~N}_{2}(g)+2 \mathrm{AlCl}_{3}(g)
$$

The relative strengths of the halogen oxoacids depend on two factors:

1. Electronegativity of the halogen. Among oxoacids with the halogen in the same oxidation state, such as the halic acids, $\mathrm{HXO}_{3}\left(\right.$ or $\left.\mathrm{HOXO}_{2}\right)$, acid strength decreases as the halogen's EN decreases:

$$
\mathrm{HOClO}_{2}>\mathrm{HOBrO}_{2}>\mathrm{HOIO}_{2}
$$

The more electronegative the halogen the more electron density it removes from the 0 - 9 bond, and the more easily the proton is lost.
2. Oxidation state of the halogen. Among oxoacids of a given halogen, such as chlorine, acid strength decreases as the oxidation state of the halogen decreases:

$$
\mathrm{HOClO}_{3}>\mathrm{HOClO}_{2}>\mathrm{HOClO}>\mathrm{HOCl}
$$

The higher the oxidation state (number of attached O atoms) of the halogen, the more electron density it pulls from the $\mathrm{O}-\mathrm{H}$ bond. We consider these trends quantitatively in Chapter 18.

Table 14.4 The Known Halogen Oxoacids*

| Central <br> Atom | Hypohalous <br> Acid (HOX) | Halous <br> Acid (HOXO) | Halic <br> Acid $\left(\mathrm{HOXO}_{2}\right)$ |
| :--- | :--- | :--- | :--- |

*Lone pairs are shown only on the halogen atom, and each atom has its lowest formal charge.

### 14.10 GROUP 8A(18): THE NOBLE GASES

The last main group consists of individual atoms too "noble" to interact with others. The Group 8A(18) elements display regular trends in physical properties and very low, if any, reactivity. The group consists of helium (He), the second most abundant element in the universe, neon ( Ne ) and argon (Ar), krypton (Kr) and xenon (Xe), the only members for which compounds have been well studied, and finally, radioactive radon (Rn). The noble gases make up about $1 \%$ by volume of the atmosphere, primarily due to the abundance of Ar. Their properties appear in the Group 8A(18) Family Portrait on page 618.

## How Can Noble Gases Form Compounds?

Lying at the far right side of the periodic table, the Group 8A(18) elements consist of individual atoms with filled outer levels and the smallest radii in their periods: even Li , the smallest alkali metal ( 152 pm ), is bigger than Rn , the largest noble gas ( 140 pm ). These elements come as close to behaving as ideal gases as any other substances. Only at very low temperatures do they condense and solidify. In fact, He is the only substance that does not solidify by a reduction in temperature alone; it requires an increase in pressure as well. Helium has the lowest melting point known $\left(-272.2^{\circ} \mathrm{C}\right.$ at 25 atm$)$, only one degree above 0 K $\left(-273.15^{\circ} \mathrm{C}\right)$, and it boils only about three degrees higher. Weak dispersion forces hold these elements in condensed states, with melting and boiling points that increase, as expected, with molar mass.

Ever since their discovery in the late $19^{\text {th }}$ century, these elements had been considered, and even formerly named, the "inert" gases. Atomic theory and, more important, all experiments had supported this idea. Then, in 1962, all this changed when the first noble gas compound wassregredPHDW, witifllegouten deveds and extremely high ionization energies, can noble gases react?

The discovery of noble gas reactivity is a classic example of clear thinking in the face of an unexpected event. At the time, a young inorganic chemist named Neil Bartlett was studying platinum fluorides, known to be strong oxidizing agents. When he accidentally exposed $\mathrm{PtF}_{6}$ to air, its deep-red color lightened slightly, and analysis showed that the $\mathrm{PtF}_{6}$ had oxidized $\mathrm{O}_{2}$ to form the ionic compound $\left[\mathrm{O}_{2}\right]^{+}\left[\mathrm{PtF}_{6}\right]^{-}$. Knowing that the ionization energy of the oxygen molecule $\left(\mathrm{O}_{2} \longrightarrow \mathrm{O}_{2}^{+}+\mathrm{e}^{-}\right.$; IE $\left.=1175 \mathrm{~kJ} / \mathrm{mol}\right)$ is very close to $\mathrm{IE}_{1}$ of xenon $(1170 \mathrm{~kJ} / \mathrm{mol})$, Bartlett reasoned that $\mathrm{PtF}_{6}$ might be able to oxidize xenon. Shortly thereafter, he prepared $\mathrm{XePtF}_{6}$, an orange-yellow solid. Within a few months, the white crystalline $\mathrm{XeF}_{2}$ and $\mathrm{XeF}_{4}$ (Figure 14.33) were also prepared. In addition to its +2 and +4 oxidation states, Xe has the +6 state in several compounds, such as $\mathrm{XeF}_{6}$, and the +8 state in the unstable oxide, $\mathrm{XeO}_{4}$. A few compounds of Kr have also been made. The xenon fluorides react rapidly in water to form HF and various other products, including different xenon compounds.

## Looking Backward and Forward: Groups 7A(17), $8 \mathrm{~A}(18)$, and $1 \mathrm{~A}(1)$

With the disappearance of metallic behavior, the Group 7A(17) elements form a host of anions, covalent oxides, and oxoanions, which change oxidation states readily in a rich aqueous chemistry. The vigorous reactivity of the halogens is in stark contrast to the inertness of their 8A neighbors. Filled outer levels render the noble gas atoms largely inert, despite a limited ability to react with the most electronegative elements, fluorine and oxygen. The least reactive family in the periodic table stands between the two most reactive: the halogens, which need one more electron to fill their outer level, and the alkali metals, which need one fewer (Figure 14.34). As you know, atomic, physical, and chemical properties change dramatically from Group $8 \mathrm{~A}(18)$ to Group 1A(1).

Figure 14.33 Crystals of xenon tetrafluoride $\left(\mathrm{XeF}_{4}\right)$.

Figure 14.34 Standing in Group 8A(18), looking backward at the halogens, Group 7A(17), and ahead to the alkali metals, Group 1A(1).

Key Atomic and Physical Properties

## Chapter Perspective

Our excursion through the bonding and reactivity patterns of the elements has come full circle, but we've only been able to touch on some of the most important features. Clearly, the properties of the atoms and the resultant physical and chemical behaviors of the elements are magnificent testimony to nature's diversity. In Chapter 15, we continue with our theme of macroscopic behavior emerging from atomic properties in an investigation of the marvelously complex organic compounds of carbon. In Chapter 22, we revisit the most important main-group elements to see how they occur in nature and how we isolate and use them.

## CHAPTER REVIEW GUIDE

The following sections provide many aids to help you study this chapter. (Numbers in parentheses refer to pages, unless noted otherwise.)

## Learning Objectives These are concepts and skills you should know after studying this chapter.

Relevant section numbers appear in parentheses.

## Understand These Concepts

Note: Many characteristic reactions appear in the "Important Reactions" section of each group's Family Portrait.

1. How hydrogen is similar to, yet different from, alkali metals and halogens; the differences between ionic, covalent, and metallic hydrides (Section 14.1)
2. Key horizontal trends in atomic properties, types of bonding, oxide acid-base properties, and redox behavior as the elements change from metals to nonmetals (Section 14.2)
3. How the $n s^{1}$ configuration accounts for the physical and chemical properties of the alkali metals (Section 14.3) 2 OD PD
4. How small atomic size and limited number of valence orbitals account for the anomalous behavior of the Period 2 member of each group (see each section for details)
5. How the $n s^{2}$ configuration accounts for the key differences between Groups $1 \mathrm{~A}(1)$ and $2 \mathrm{~A}(2)$ (Section 14.4)
6. The basis of the three important diagonal relationships ( $\mathrm{Li} / \mathrm{Mg}$, Be/Al, B/Si) (Sections 14.4-14.6)
7. How the presence of inner $(n-1) d$ electrons affects properties in Group 3A(13) (Section 14.5)
8. Patterns among larger members of Groups $3 \mathrm{~A}(13)$ to $6 \mathrm{~A}(16)$ : two common oxidation states (inert-pair effect), lower state more important down the group, and more basic lower oxide (Sections 14.5-14.8)
9. How boron attains an octet of electrons (Section 14.5)
10. The effect of bonding on the physical behavior of Groups $4 \mathrm{~A}(14)$ to $6 \mathrm{~A}(16)$ (Sections 14.6-14.8)
11. Allotropism in carbon, phosphorus, and sulfur (Sections 14.6-14.8)
12. How atomic properties lead to catenation and multiple bonds in organic compounds (Section 14.6)
13. Structures and properties of the silicates and silicones (Section 14.6)
14. Patterns of behavior among hydrides and halides of Groups $5 \mathrm{~A}(15)$ and 6A(16) (Sections 14.7, 14.8)
15. The meaning of disproportionation (Section 14.7) and its importance in halogen aqueous chemistry (Section 14.9)
16. Structure and chemistry of the nitrogen oxides and oxoacids (Section 14.7)
Fif.SArtife ant chemistry of the phosphorus oxides and oxoacids (Section 14.7)
17. Dehydration-condensation reactions and polyphosphate structures (Section 14.7)
18. Structure and chemistry of the sulfur oxides and oxoacids (Section 14.8)
19. How the $n s^{2} n p^{5}$ configuration accounts for halogen reactivity with metals (Section 14.9)
20. Why the oxidation states of an element change by two units (Section 14.9)
21. Structure and chemistry of the halogen oxides and oxoacids (Section 14.9)
22. How the $n s^{2} n p^{6}$ configuration accounts for the relative inertness of the noble gases (Section 14.10)

Key Terms These important terms appear in boldface in the chapter and are defined again in the Glossary.

## PROBLEMS

Problems with colored numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and provide the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.
Note: This set begins with problems based on material from the Interchapter.

## Interchapter Review

## - Concept Review Questions

14.1 (a) Define the four atomic properties that are reviewed in the Interchapter.
(b) To what do the three parts of the electroneonfegration (nt) $\mathbf{D}$ correlate?
(c) Which part of the electron configuration is primarily associated with the size of the atom?
(d) What is the major distinction between the outer electron configurations within a group and those within a period?
(e) What correlation, if any, exists between the group number and the number of valence electrons?
14.2 (a) What trends, if any, exist for $Z_{\text {eff }}$ across a period and down a group? (b) How does $Z_{\text {eff }}$ influence atomic size, $\mathrm{IE}_{1}$, and EN across a period?
14.3 Iodine monochloride and elemental bromine have nearly the same molar mass and liquid density but very different boiling points. (a) What molecular property is primarily responsible for this difference in boiling point? What atomic property gives rise to it? Explain. (b) Which substance has a higher boiling point? Why?
14.4 How does the trend in atomic size differ from the trend in ionization energy? Explain.
14.5 How are bond energy, bond length, and reactivity related for similar compounds?
14.6 How are covalent and metallic bonding similar? How are they different?
14.7 If the leftmost element in a period combined with each of the others in the period, how would the type of bonding change from left to right? Explain in terms of atomic properties.
14.8 Why is rotation about the bond axis possible for singlebonded atoms but not double-bonded atoms?
14.9 Explain the horizontal irregularity in size of the most common ions of Period 3 elements.
14.10 Is S ${ }^{2-}$ larger or smaller than $\mathrm{Cl}^{-}$? Is $\mathrm{Mg}^{2+}$ larger or smaller than $\mathrm{Na}^{+}$? Explain.
14.11 How do each of the following correlate with the electronegativity of the elements: (a) the type of bonding in element oxides; (b) the acid-base behavior of element oxides?
14.12 (a) How does the metallic character of an element correlate with the acidity of its oxide? (b) What trends, if any, exist in oxide basicity across a period and down a group?
14.13 How are atomic size, $\mathrm{IE}_{1}$, and EN related to redox behavior of the elements in Groups 1A(1), 2A(2), 6A(16), and 7A(17)?
14.14 How do the physical properties of a network covalent solid and a molecular covalent solid differ? Why?

## - Skill-Building Exercises (grouped in similar pairs)

14.15 Rank the following elements in order of increasing
(a) atomic size: $\mathrm{Ba}, \mathrm{Mg}, \mathrm{Sr}$
(b) $\mathrm{IE}_{1}: \mathrm{P}, \mathrm{Na}, \mathrm{Al}$
(c) $\mathrm{EN}: \mathrm{Br}, \mathrm{Cl}, \mathrm{Se}$
(d) no. of valence electrons: $\mathrm{Bi}, \mathrm{Ga}, \mathrm{Sn}$
14.16 Rank the following elements in order of decreasing
(a) atomic size: N, Si, P
(b) $\mathrm{IE}_{1}: \mathrm{Kr}, \mathrm{K}, \mathrm{Ar}$
(c) ENIn, RbICEI (d) no. of valence electrons: $\mathrm{Sb}, \mathrm{S}, \mathrm{Cs}$
14.17 Which of the following pairs react to form ionic compounds: (a) Cl and Br ; (b) Na and Br ; (c) P and Se ; (d) H and Ba ?
14.18 Which of the following pairs react to form covalent compounds: (a) Be and C ; (b) Sr and O ; (c) Ca and Cl ; (d) P and F ?
14.19 Draw a Lewis structure for a compound with a bond order of 2 throughout the molecule.
14.20 Draw a Lewis structure for a polyatomic ion with a fractional bond order throughout the molecule.
14.21 Rank the following in order of increasing bond length: $\mathrm{SiCl}_{4}, \mathrm{CF}_{4}, \mathrm{GeBr}_{4}$.
14.22 Rank the following in order of decreasing bond energy: $\mathrm{NF}_{3}, \mathrm{NI}_{3}, \mathrm{NCl}_{3}$.
14.23 Rank the following in order of increasing radius:
(a) $\mathrm{O}^{2-}, \mathrm{F}^{-}, \mathrm{Na}^{+}$
(b) $\mathrm{S}^{2-}, \mathrm{P}^{3-}, \mathrm{Cl}^{-}$
14.24 Rank the following in order of decreasing radius:
(a) $\mathrm{Ca}^{2+}, \mathrm{K}^{+}, \mathrm{Ga}^{3+}$
(b) $\mathrm{Br}^{-}, \mathrm{Sr}^{2+}, \mathrm{Rb}^{+}$
14.25 Rank $\mathrm{O}^{-}, \mathrm{O}^{2-}$, and O in order of increasing size.
14.26 Rank $\mathrm{Tl}^{3+}, \mathrm{Tl}$, and $\mathrm{Tl}^{+}$in order of decreasing size.
14.27 Which member of each pair gives the more basic solution in water: (a) CaO or $\mathrm{SO}_{3}$; (b) BeO or BaO ; (c) $\mathrm{CO}_{2}$ or $\mathrm{SO}_{2}$; (d) $\mathrm{P}_{4} \mathrm{O}_{10}$ or $\mathrm{K}_{2} \mathrm{O}$ ? For the pair in part (a), write an equation for the dissolving of each oxide to support your answer.
14.28 Which member of each pair gives the more acidic solution in water: (a) $\mathrm{CO}_{2}$ or SrO ; (b) SnO or $\mathrm{SnO}_{2}$; (c) $\mathrm{Cl}_{2} \mathrm{O}$ or $\mathrm{Na}_{2} \mathrm{O}$; (d) $\mathrm{SO}_{2}$ or MgO ? For the pair in part (a), write an equation for the dissolving of each oxide to support your answer.
14.29 Which member of each pair has more covalent character in its bonds: (a) LiCl or KCl ; (b) $\mathrm{AlCl}_{3}$ or $\mathrm{PCl}_{3}$; (c) $\mathrm{NCl}_{3}$ or $\mathrm{AsCl}_{3}$ ? 14.30 Which member of each pair has more ionic character in its bonds: (a) $\mathrm{BeF}_{2}$ or $\mathrm{CaF}_{2}$; (b) $\mathrm{PbF}_{2}$ or $\mathrm{PbF}_{4}$; (c) $\mathrm{GeF}_{4}$ or $\mathrm{PF}_{3}$ ?
14.31 Rank the following in order of increasing
(a) Melting point: $\mathrm{Na}, \mathrm{Si}, \mathrm{Ar}$
(b) $\Delta H_{\text {fus }}: \mathrm{Rb}, \mathrm{Cs}, \mathrm{Li}$
14.32 Rank the following in order of decreasing
(a) Boiling point: $\mathrm{O}_{2}, \mathrm{Br}_{2}, \mathrm{As}(s)$
(b) $\Delta H_{\text {vap }}: \mathrm{Cl}_{2}, \mathrm{Ar}, \mathrm{I}_{2}$

## Hydrogen, the Simplest Atom

## - Concept Review Questions

14.33 Hydrogen has only one proton, but its $\mathrm{IE}_{1}$ is much greater than that of lithium, which has three protons. Explain.
14.34 Sketch a periodic table, and label the areas containing elements that give rise to the three types of hydrides.

## - Skill-Building Exercises (grouped in similar pairs)

14.35 Draw Lewis structures for the following compounds, and predict which member of each pair will form hydrogen bonds:
(a) $\mathrm{NF}_{3}$ or $\mathrm{NH}_{3}$
(b) $\mathrm{CH}_{3} \mathrm{OCH}_{3}$ or $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$
14.36 Draw Lewis structures for the following compounds, and predict which member of each pair will form hydrogen bonds:
(a) $\mathrm{NH}_{3}$ or $\mathrm{AsH}_{3}$
(b) $\mathrm{CH}_{4}$ or $\mathrm{H}_{2} \mathrm{O}$
14.37 Complete and balance the following equations:
(a) An active metal reacting with acid,
$\mathrm{Al}(s)+\mathrm{HCl}(a q) \longrightarrow$
(b) A saltlike (alkali metal) hydride reacting with water,

$$
\mathrm{LiH}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow
$$

14.38 Complete and balance the followingequations; PDE
(a) A saltlike (alkaline earth metal) hydrrde reaeting with water, $\mathrm{CaH}_{2}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$
(b) Reduction of a metal halide by hydrogen to form a metal,

$$
\mathrm{PdCl}_{2}(a q)+\mathrm{H}_{2}(g) \longrightarrow
$$

## - Problems in Context

14.39 Compounds such as $\mathrm{NaBH}_{4}, \mathrm{Al}\left(\mathrm{BH}_{4}\right)_{3}$, and $\mathrm{LiAlH}_{4}$ are complex hydrides used as reducing agents in many syntheses.
(a) Give the oxidation state of each element in these compounds.
(b) Write a Lewis structure for the polyatomic anion in $\mathrm{NaBH}_{4}$, and predict its shape.
14.40 Unlike the $\mathrm{F}^{-}$ion, which has an ionic radius close to 133 pm in all alkali metal fluorides, the ionic radius of $\mathrm{H}^{-}$varies from 137 pm in LiH to 152 pm in CsH . Suggest an explanation for the large variability in the size of $\mathrm{H}^{-}$but not $\mathrm{F}^{-}$.

## Trends Across the Periodic Table

## - Concept Review Questions

14.41 How does the maximum oxidation number vary across a period in the main groups? Is the pattern in Period 2 different?
14.42 What correlation, if any, exists for the Period 2 elements between group number and the number of covalent bonds the element typically forms? How is the correlation different for elements in Periods 3 to 6 ?
14.43 Each of the chemically active Period 2 elements forms stable compounds that have bonds to fluorine.
(a) What are the names and formulas of these compounds?
(b) Does $\Delta \mathrm{EN}$ increase or decrease left to right across the period?
(c) Does percent ionic character increase or decrease left to right?
(d) Draw Lewis structures for these compounds.
14.44 Period 6 is unusual in several ways.
(a) It is the longest period in the table. How many elements belong to Period 6 ? How many metals?
(b) It contains no metalloids. Where is the metal/nonmetal boundary in Period 6?
14.45 An element forms an oxide, $\mathrm{E}_{2} \mathrm{O}_{3}$, and a fluoride, $\mathrm{EF}_{3}$.
(a) Of which two groups might E be a member?
(b) How does the group to which E belongs affect the properties of the oxide and the fluoride?
14.46 Fluorine lies between oxygen and neon in Period 2. Whereas atomic sizes and ionization energies of these three elements change smoothly, their electronegativities display a dramatic change. What is this change, and how do their electron configurations explain it?

## Group 1A(1): The Alkali Metals

## - Concept Review Questions

14.47 Lithium salts are often much less soluble in water than the corresponding salts of other alkali metals. For example, at $18^{\circ} \mathrm{C}$, the concentration of a saturated LiF solution is $1.0 \times 10^{-2} M$, whereas that of a saturated KF solution is 1.6 M . How would you explain this behavior?
14.48 The alkali metals play virtually the same general chemical role in all their reactions. (a) What is this role? (b) How is it based on atomic properties? (c) Using sodium, write two balanced equations that illustrate this role.
14.49 How do atomic properties account for the low densities of the Group $1 \mathrm{~A}(1)$ elements?

## Erlshtteraiding Exercises (grouped in similar pairs)

14.50 Each of the following properties shows a regular trend in Group 1A(1). Predict whether each increases or decreases down the group: (a) density; (b) ionic size; (c) $\mathrm{E}-\mathrm{E}$ bond energy; (d) $\mathrm{IE}_{1}$; (e) magnitude of $\Delta H_{\mathrm{hydr}}$ of $\mathrm{E}^{+}$ion.
14.51 Each of the following properties shows a regular trend in Group 1A(1). Predict whether each increases or decreases up the group: (a) melting point; (b) E-E bond length; (c) hardness; (d) molar volume; (e) lattice energy of EBr .
14.52 Write a balanced equation for the formation from its elements of sodium peroxide, an industrial bleach.
14.53 Write a balanced equation for the formation of rubidium bromide through a reaction of a strong acid and a strong base.

## - Problems in Context

14.54 Although the alkali metal halides can be prepared directly from the elements, the far less expensive industrial route is treatment of the carbonate or hydroxide with aqueous hydrohalic acid (HX) followed by recrystallization. Balance the reaction between potassium carbonate and aqueous hydriodic acid.
14.55 Lithium forms several useful organolithium compounds. Calculate the mass percent of Li in the following:
(a) Lithium stearate $\left(\mathrm{C}_{17} \mathrm{H}_{35} \mathrm{COOLi}\right)$, a water-resistant grease used in cars because it does not harden at cold temperatures
(b) Butyllithium $\left(\mathrm{LiC}_{4} \mathrm{H}_{9}\right)$, a reagent in organic syntheses

## Group 2A(2): The Alkaline Earth Metals

## - Concept Review Questions

14.56 How do Groups $1 \mathrm{~A}(1)$ and $2 \mathrm{~A}(2)$ compare with respect to reaction of the metals with water?
14.57 Alkaline earth metals are involved in two key diagonal relationships in the periodic table. (a) Give the two pairs of elements in these diagonal relationships. (b) For each pair, cite two similarities that demonstrate the relationship. (c) Why are the members of each pair so similar in behavior?
14.58 The melting points of alkaline earth metals are many times higher than those of the alkali metals. Explain this difference on the basis of atomic properties. Name three other physical properties for which Group 2A(2) metals have higher values than the corresponding $1 \mathrm{~A}(1)$ metals.

## - Skill-Building Exercises (grouped in similar pairs)

14.59 Write a balanced equation for each reaction:
(a) "Slaking" of lime (treatment with water)
(b) Combustion of calcium in air
14.60 Write a balanced equation for each reaction:
(a) Thermal decomposition of witherite (barium carbonate)
(b) Neutralization of stomach acid $(\mathrm{HCl})$ by milk of magnesia (magnesium hydroxide)

## - Problems in Context

14.61 Lime $(\mathrm{CaO})$ is one of the most abundantly produced chemicals in the world. Write balanced equations for
(a) The preparation of lime from natural sources
(b) The use of slaked lime to remove $\mathrm{SO}_{2}$ from flue gases
(c) The reaction of lime with arsenic $\operatorname{acid}\left(\mathrm{H}_{3} \mathrm{AsO}_{4}\right)$ to manufacture the insecticide calcium arsenate
(d) The regeneration of NaOH in the paper industry by reaction of lime with aqueous sodium carbonate

14.62 In some reactions, Be behaves like a typical alkaline earth | metal in in others, it does not. Complete and batance thefodowies |
| :--- |
| equations: | equations:

(a) $\mathrm{BeO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$
(b) $\mathrm{BeCl}_{2}(l)+\mathrm{Cl}^{-}(l$; from molten NaCl$) \longrightarrow$

In which reaction does Be behave like the other Group 2A(2) members?

## Group 3A(13): The Boron Family

## - Concept Review Questions

14.63 How do the transition metals in Period 4 affect the pattern of ionization energies in Group 3A(13)? How does this pattern compare with that in Group 3B(3)?
14.64 How do the acidities of aqueous solutions of $\mathrm{Tl}_{2} \mathrm{O}$ and $\mathrm{Tl}_{2} \mathrm{O}_{3}$ compare with each other? Explain.
14.65 Despite the expected decrease in atomic size, there is an unexpected drop in the first ionization energy between Groups $2 \mathrm{~A}(2)$ and $3 \mathrm{~A}(13)$ in Periods 2 through 4. Explain this pattern in terms of electron configurations and orbital energies.
14.66 Many compounds of Group 3A(13) elements have chemical behavior that reflects an electron deficiency.
(a) What is the meaning of electron deficiency?
(b) Give two reactions that illustrate this behavior.
14.67 Boron's chemistry is not typical of its group.
(a) Cite three ways in which boron and its compounds differ significantly from the other $3 \mathrm{~A}(13)$ members and their compounds.
(b) What is the reason for these differences?

## - Skill-Building Exercises (grouped in similar pairs)

14.68 Rank the following oxides in order of increasing aqueous acidity: $\mathrm{Ga}_{2} \mathrm{O}_{3}, \mathrm{Al}_{2} \mathrm{O}_{3}, \mathrm{In}_{2} \mathrm{O}_{3}$.
14.69 Rank the following hydroxides in order of increasing aqueous basicity: $\mathrm{Al}(\mathrm{OH})_{3}, \mathrm{~B}(\mathrm{OH})_{3}, \operatorname{In}(\mathrm{OH})_{3}$.
14.70 Thallium forms the compound $\mathrm{TII}_{3}$. What is the apparent oxidation state of Tl in this compound? Given that the anion is $\mathrm{I}_{3}{ }^{-}$, what is the actual oxidation state of Tl ? Draw the shape of the anion, giving its VSEPR class and bond angles. Propose a reason why the compound does not exist as $\left(\mathrm{Tl}^{3+}\right)\left(\mathrm{I}^{-}\right)_{3}$.
14.71 Very stable dihalides of the Group $3 \mathrm{~A}(13)$ metals are known. What is the apparent oxidation state of Ga in $\mathrm{GaCl}_{2}$ ? Given that $\mathrm{GaCl}_{2}$ consists of a $\mathrm{Ga}^{+}$cation and a $\mathrm{GaCl}_{4}{ }^{-}$anion, what are the actual oxidation states of Ga? Draw the shape of the anion, giving its VSEPR class and bond angles.

## - Problems in Context

14.72 Give the name and symbol or formula of a Group 3A(13) element or compound that fits each description or use:
(a) Component of heat-resistant (Pyrex-type) glass
(b) Manufacture of high-speed computer chips
(c) Largest temperature range for liquid state of an element
(d) Elemental substance with three-center, two-electron bonds
(e) Metal protected from oxidation by adherent oxide coat
(f) Mild antibacterial agent (e.g., for eye infections)
(g) Toxic metal that lies between two other toxic metals
14.73 Indium (In) reacts with HCl to form a diamagnetic solid with the formula $\mathrm{InCl}_{2}$. (a) Write condensed electron configurations for $\mathrm{In}, \mathrm{In}^{+}, \mathrm{In}^{2+}$, and $\mathrm{In}^{3+}$. (b) Which of these species is (are) diamagnetic and which paramagnetic? (c) What is the apparent oxidation state of In in $\mathrm{InCl}_{2}$ ? (d) Given your answers to parts (b) and (c), explain how $\mathrm{InCl}_{2}$ can be diamagnetic.
14.74 Use VSEPR theory to draw structures, with ideal bond angles, for boric acid and the anion it forms in reaction with water. 14.75, Boron nitride (BN) has a structure similar to graphite, but is a wite nns ator fatarthan a black conductor. It is synthesized by heating diboron trioxide with ammonia at about $1000^{\circ} \mathrm{C}$.
(a) Write a balanced equation for the formation of BN ; water forms also.
(b) Calculate $\Delta H_{\mathrm{rxn}}^{\circ}$ for the production of $\mathrm{BN}\left(\Delta H_{\mathrm{f}}^{\circ}\right.$ of BN is $-254 \mathrm{~kJ} / \mathrm{mol}$ ).
(c) Boron is obtained from the mineral borax, $\mathrm{Na}_{2} \mathrm{~B}_{4} \mathrm{O}_{7} \cdot 10 \mathrm{H}_{2} \mathrm{O}$. How much borax is needed to produce 1.0 kg of BN , assuming $72 \%$ yield?

## Group 4A(14): The Carbon Family

## Concept Review Questions

14.76 How does the basicity of $\mathrm{SnO}_{2}$ in water compare with that of $\mathrm{CO}_{2}$ ? Explain.
14.77 Nearly every compound of silicon has the element in the +4 oxidation state. In contrast, most compounds of lead have the element in the +2 state.
(a) What general observation do these facts illustrate?
(b) Explain in terms of atomic and molecular properties.
(c) Give an analogous example from Group 3A(13).
14.78 The sum of $\mathrm{IE}_{1}$ through $\mathrm{IE}_{4}$ for Group $4 \mathrm{~A}(14)$ elements shows a decrease from C to Si , a slight increase from Si to Ge , a decrease from Ge to Sn , and an increase from Sn to Pb .
(a) What is the expected trend for IEs down a group?
(b) Suggest a reason for the deviations in Group 4A(14).
(c) Which group might show even greater deviations?
14.79 Give explanations for the large drops in melting point from C to Si and from Ge to Sn .
14.80 What is an allotrope? Name two Group 4A(14) elements that exhibit allotropism, and identify two of their allotropes.
14.81 Even though EN values vary relatively little down Group $4 \mathrm{~A}(14)$, the elements change from nonmetal to metal. Explain.
14.82 How do atomic properties account for the enormous number of carbon compounds? Why don't other Group 4A(14) elements behave similarly?

## Skill-Building Exercises (grouped in similar pairs)

14.83 Draw a Lewis structure for
(a) The cyclic silicate ion $\mathrm{Si}_{4} \mathrm{O}_{12}{ }^{8-}$
(b) A cyclic hydrocarbon with formula $\mathrm{C}_{4} \mathrm{H}_{8}$
14.84 Draw a Lewis structure for
(a) The cyclic silicate ion $\mathrm{Si}_{6} \mathrm{O}_{18}{ }^{12-}$
(b) A cyclic hydrocarbon with formula $\mathrm{C}_{6} \mathrm{H}_{12}$
14.85 Show three units of a linear silicone polymer made from $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{Si}(\mathrm{OH})_{2}$ with some $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{SiOH}$ added to end the chain.
14.86 Show two chains of three units each of a sheet silicone polymer made from $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{Si}(\mathrm{OH})_{2}$ with $\mathrm{CH}_{3} \mathrm{Si}(\mathrm{OH})_{3}$ added to crosslink the chains.

## - Problems in Context

14.87 Zeolite A, $\mathrm{Na}_{12}\left[\left(\mathrm{AlO}_{2}\right)_{12}\left(\mathrm{SiO}_{2}\right)_{12}\right] \cdot 27 \mathrm{H}_{2} \mathrm{O}$, is used to soften water by replacing $\mathrm{Ca}^{2+}$ and $\mathrm{Mg}^{2+}$ with $\mathrm{Na}^{+}$. Hard water from a certain source is $4.5 \times 10^{-3} M \mathrm{Ca}^{2+}$ and $9.2 \times 10^{-4} \mathrm{M} \mathrm{Mg}^{2+}$, and a pipe delivers $25,000 \mathrm{~L}$ of this hard water per day. What mass (in kg ) of zeolite A is needed to soften a week's supply of the water? (Assume zeolite A loses its capacity to exchange ions when $85 \mathrm{~mol} \%$ of its $\mathrm{Na}^{+}$has been lost.)
14.88 Give the name and symbol or formula of a Group 4A(14) element or compound that fits each description or use:
(a) Hardest known natural substance
(b) Medicinal antacid

Apago PDF
(c) Atmospheric gas implicated in the greenhouse effect
(d) Waterproofing polymer based on silicon
(e) Synthetic abrasive composed entirely of elements in the group
(f) Product formed when coke burns in a limited supply of air
(g) Toxic metal found in plumbing and paints
14.89 One similarity between B and Si is the explosive combustion of their hydrides in air. Write balanced equations for the combustion of $\mathrm{B}_{2} \mathrm{H}_{6}$ and of $\mathrm{Si}_{4} \mathrm{H}_{10}$.

## Group 5A(15): The Nitrogen Family <br> Concept Review Questions

14.90 Which Group 5A(15) elements form trihalides? Pentahalides? Explain.
14.91 As you move down Group 5A(15), the melting points of the elements increase and then decrease. Explain.
14.92 (a) What is the range of oxidation states shown by the elements of Group 5A(15) as you move down the group? (b) How does this range illustrate the general rule for the range of oxidation states in groups on the right side of the periodic table?
14.93 Bismuth $(\mathrm{V})$ compounds are such powerful oxidizing agents that they have not been prepared in pure form. How is this fact consistent with the location of Bi in the periodic table?
14.94 Rank the following oxides in order of increasing acidity in water: $\mathrm{Sb}_{2} \mathrm{O}_{3}, \mathrm{Bi}_{2} \mathrm{O}_{3}, \mathrm{P}_{4} \mathrm{O}_{10}, \mathrm{Sb}_{2} \mathrm{O}_{5}$.

## - Skill-Building Exercises (grouped in similar pairs)

14.95 Assuming acid strength relates directly to electronegativity of the central atom, rank $\mathrm{H}_{3} \mathrm{PO}_{4}, \mathrm{HNO}_{3}$, and $\mathrm{H}_{3} \mathrm{AsO}_{4}$ in order of increasing acid strength.
14.96 Assuming acid strength relates directly to number of O atoms bonded to the central atom, rank $\mathrm{H}_{2} \mathrm{~N}_{2} \mathrm{O}_{2}$ [or $(\mathrm{HON})_{2}$ ]; $\mathrm{HNO}_{3}$ (or $\mathrm{HONO}_{2}$ ); and $\mathrm{HNO}_{2}$ (or HONO) in order of decreasing acid strength.
14.97 Complete and balance the following:
(a) $\mathrm{As}(s)+$ excess $\mathrm{O}_{2}(g) \longrightarrow$
(b) $\mathrm{Bi}(s)+$ excess $\mathrm{F}_{2}(g) \longrightarrow$
(c) $\mathrm{Ca}_{3} \mathrm{As}_{2}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$
14.98 Complete and balance the following:
(a) Excess $\mathrm{Sb}(s)+\mathrm{Br}_{2}(l) \longrightarrow$
(b) $\mathrm{HNO}_{3}(a q)+\mathrm{MgCO}_{3}(s) \longrightarrow$
(c) $\mathrm{K}_{2} \mathrm{HPO}_{4}(s) \xrightarrow{\Delta}$
14.99 Complete and balance the following:
(a) $\mathrm{N}_{2}(g)+\mathrm{Al}(s) \xrightarrow{\Delta}$
(b) $\mathrm{PF}_{5}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$
14.100 Complete and balance the following:
(a) $\mathrm{AsCl}_{3}(l)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$
(b) $\mathrm{Sb}_{2} \mathrm{O}_{3}(s)+\mathrm{NaOH}(a q) \longrightarrow$
14.101 Based on the relative sizes of F and Cl , predict the structure of $\mathrm{PF}_{2} \mathrm{Cl}_{3}$.
14.102 Use the VSEPR model to predict the structure of the cyclic ion $\mathrm{P}_{3} \mathrm{O}_{9}{ }^{3-}$.

## - Problems in Context

14.103 The pentafluorides of the larger members of Group 5A(15) have been prepared, but N can have only eight electrons. A claim has been made that, at low temperatures, a compound with the empirical formula $\mathrm{NF}_{5}$ forms. Draw a possible Lewis structure for this compound. (Hint: $\mathrm{NF}_{5}$ is ionic.)
14.104 Give the name and symbol or formula of a Group 5A(15)

Frementreompound that fits each description or use:
(a) Hydride produced at multimillion-ton level
(b) Element(s) essential in plant nutrition
(c) Hydride used to manufacture rocket propellants and drugs
(d) Odd-electron molecule (two examples)
(e) Amphoteric hydroxide with a 5A element in its +3 state
(f) Phosphorus-containing water softener
(g) Element that is an electrical conductor
14.105 In addition to those in Table 14.3, other less stable nitrogen oxides exist. Draw a Lewis structure for each of the following:
(a) $\mathrm{N}_{2} \mathrm{O}_{2}$, a dimer of nitrogen monoxide with an $\mathrm{N}-\mathrm{N}$ bond
(b) $\mathrm{N}_{2} \mathrm{O}_{2}$, a dimer of nitrogen monoxide with no $\mathrm{N}-\mathrm{N}$ bond
(c) $\mathrm{N}_{2} \mathrm{O}_{3}$ with no $\mathrm{N}-\mathrm{N}$ bond
(d) $\mathrm{NO}^{+}$and $\mathrm{NO}_{3}{ }^{-}$, products of the ionization of liquid $\mathrm{N}_{2} \mathrm{O}_{4}$
14.106 Nitrous oxide $\left(\mathrm{N}_{2} \mathrm{O}\right)$, the "laughing gas" used as an anesthetic by dentists, is made by thermal decomposition of solid $\mathrm{NH}_{4} \mathrm{NO}_{3}$. Write a balanced equation for this reaction. What are the oxidation states of N in $\mathrm{NH}_{4} \mathrm{NO}_{3}$ and in $\mathrm{N}_{2} \mathrm{O}$ ?
14.107 Write balanced equations for the thermal decomposition of potassium nitrate ( $\mathrm{O}_{2}$ is also formed in both cases): (a) at low temperature to the nitrite; (b) at high temperature to the metal oxide and nitrogen.

## Group 6A(16): The Oxygen Family <br> - Concept Review Questions

14.108 Rank the following in order of increasing electrical conductivity, and explain your ranking: Po, S, Se.
14.109 The oxygen and nitrogen families have some obvious similarities and differences.
(a) State two general physical similarities between Group $5 \mathrm{~A}(15)$ and $6 \mathrm{~A}(16)$ elements.
(b) State two general chemical similarities between Group $5 \mathrm{~A}(15)$ and $6 \mathrm{~A}(16)$ elements.
(c) State two chemical similarities between P and S .
(d) State two physical similarities between N and O .
(e) State two chemical differences between N and O .
14.110 A molecular property of the Group $6 \mathrm{~A}(16)$ hydrides changes abruptly down the group. This change has been explained in terms of a change in orbital hybridization.
(a) Between what periods does the change occur?
(b) What is the change in the molecular property?
(c) What is the change in hybridization?
(d) What other group displays a similar change?

## Skill-Building Exercises (grouped in similar pairs)

14.111 Complete and balance the following:
(a) $\mathrm{NaHSO}_{4}(a q)+\mathrm{NaOH}(a q) \longrightarrow$
(b) $\mathrm{S}_{8}(s)+$ excess $\mathrm{F}_{2}(g) \longrightarrow$
(c) $\mathrm{FeS}(s)+\mathrm{HCl}(a q) \longrightarrow$
(d) $\mathrm{Te}(s)+\mathrm{I}_{2}(s) \longrightarrow$
14.112 Complete and balance the following:
(a) $\mathrm{H}_{2} \mathrm{~S}(g)+\mathrm{O}_{2}(g) \longrightarrow$
(b) $\mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$
(c) $\mathrm{SF}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$
(d) $\mathrm{Al}_{2} \mathrm{Se}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$
14.113 Is each oxide basic, acidic, or amphoteric in water: (a) $\mathrm{SeO}_{2}$; (b) $\mathrm{N}_{2} \mathrm{O}_{3}$; (c) $\mathrm{K}_{2} \mathrm{O}$; (d) BeO ; (e) BaO ?
14.114 Is each oxide basic, acidic, or amphoteric in water:
(a) MgO ;
(b) $\mathrm{N}_{2} \mathrm{O}_{5}$; (c) CaO ;
(d) $\mathrm{CO}_{2}$; (e) $\mathrm{TeO}_{2}$ ?
14.122 (a) What are the common oxidation states of the halogens?
(b) Give an explanation based on electron configuration for the range and values of the oxidation states of chlorine.
(c) Why is fluorine an exception to the pattern of oxidation states found for the other group members?
14.123 How many electrons does a halogen atom need to complete its octet? Give examples of the ways a Cl atom can do so. 14.124 Select the stronger bond in each pair:
(a) $\mathrm{Cl}-\mathrm{Cl}$ or $\mathrm{Br}-\mathrm{Br}$
(b) $\mathrm{Br}-\mathrm{Br}$ or $\mathrm{I}-\mathrm{I}$
(c) $\mathrm{F}-\mathrm{F}$ or $\mathrm{Cl}-\mathrm{Cl}$. Why doesn't the $\mathrm{F}-\mathrm{F}$ bond strength follow the group trend?
14.125 In addition to interhalogen compounds, many interhalogen ions exist. Would you expect interhalogen ions with a $1+$ or a 1 - charge to have an even or odd number of atoms? Explain.
14.126 (a) A halogen $\left(\mathrm{X}_{2}\right)$ disproportionates in base in several steps to $\mathrm{X}^{-}$and $\mathrm{XO}_{3}{ }^{-}$. Write the overall equation for the disproportionation of $\mathrm{Br}_{2}$ to $\mathrm{Br}^{-}$and $\mathrm{BrO}_{3}{ }^{-}$.
(b) Write a balanced equation for the reaction of $\mathrm{ClF}_{5}$ with aqueous base (see the reaction of $\mathrm{BrF}_{5}$ shown on p .614 ).

## - Skill-Building Exercises (grouped in similar pairs)

14.127 Complete and balance the following equations. If no reaction occurs, write NR:
(a) $\mathrm{Rb}(s)+\mathrm{Br}_{2}(l) \longrightarrow$
(b) $\mathrm{I}_{2}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$
(c) $\mathrm{Br}_{2}(l)+\mathrm{I}^{-}(a q) \longrightarrow$
(d) $\mathrm{CaF}_{2}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(l) \longrightarrow$
14.128 Complete and balance the following equations. If no reaction occurs, write NR:
(a) $\mathrm{H}_{3} \mathrm{PO}_{4}(l)+\mathrm{NaI}(s) \longrightarrow$
(b) $\mathrm{Cl}_{2}(g)+\mathrm{I}^{-}(a q) \longrightarrow$
(c) $\mathrm{Br}_{2}(l)+\mathrm{Cl}^{-}(a q) \longrightarrow$
(d) $\mathrm{ClF}(g)+\mathrm{F}_{2}(g) \longrightarrow$
14.12\% Rank the following acids in order of increasing acid strength: $\mathrm{HClO}, \mathrm{HClO}_{2}, \mathrm{HBrO}, \mathrm{HIO}$.
14.130 Rank the following acids in order of decreasing acid strength: $\mathrm{HBrO}_{3}, \mathrm{HBrO}_{4}, \mathrm{HIO}_{3}, \mathrm{HClO}_{4}$.

## - Problems in Context

14.131 Give the name and symbol or formula of a Group 7A(17) element or compound that fits each description or use:
(a) Used in etching glass
(b) Naturally occurring source (ore) of fluorine
(c) Oxide used in bleaching paper pulp and textiles
(d) Weakest hydrohalic acid
(e) Compound used to prevent goiter (thyroid disorder)
(f) Element that is produced in the largest quantity
(g) Organic chloride used to make plastics
14.132 An industrial chemist treats solid NaCl with concentrated $\mathrm{H}_{2} \mathrm{SO}_{4}$ and obtains gaseous HCl and $\mathrm{NaHSO}_{4}$. When she substitutes solid NaI for NaCl , gaseous $\mathrm{H}_{2} \mathrm{~S}$, solid $\mathrm{I}_{2}$, and $\mathrm{S}_{8}$ are obtained but no HI. (a) What type of reaction did the $\mathrm{H}_{2} \mathrm{SO}_{4}$ undergo with NaI? (b) Why does NaI , but not NaCl , cause this type of reaction? (c) To produce $\mathrm{HI}(g)$ by the reaction of NaI with an acid, how does the acid have to differ from sulfuric acid?
14.133 Rank the halogens $\mathrm{Cl}_{2}, \mathrm{Br}_{2}$, and $\mathrm{I}_{2}$ in order of increasing oxidizing strength based on their products with metallic Re: $\mathrm{ReCl}_{6}, \mathrm{ReBr}_{5}, \mathrm{ReI}_{4}$. Explain your ranking.

## Group 8A(18): The Noble Gases

14.134 Which noble gas is the most abundant in the universe? In Earth's atmosphere?
14.135 What oxidation states does Xe show in its compounds?
14.136 Why do the noble gases have such low boiling points?
14.137 Explain why Xe, and to a limited extent Kr , form compounds, whereas $\mathrm{He}, \mathrm{Ne}$, and Ar do not.
14.138 (a) Why do stable xenon fluorides have an even number of F atoms? (b) Why do the ionic species $\mathrm{XeF}_{3}{ }^{+}$and $\mathrm{XeF}_{7}{ }^{-}$have odd numbers of F atoms? (c) Predict the shape of $\mathrm{XeF}_{3}{ }^{+}$.

## Comprehensive Problems

14.139 Xenon tetrafluoride reacts with antimony pentafluoride to form the following ionic complex: $\left[\mathrm{XeF}_{3}\right]^{+}\left[\mathrm{SbF}_{6}\right]^{-}$. (a) Which of the following illustrates the molecular shapes of the reactants and product? (b) How, if at all, does the hybridization of xenon change in the reaction?

14.140 Given the following information,

$$
\begin{aligned}
\mathrm{H}^{+}(g)+\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}(g) & \Delta H=-720 \mathrm{~kJ} \\
\mathrm{H}^{+}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}(a q) & \Delta H=-1090 \mathrm{~kJ} \\
\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(g) & \Delta H=40.7 \mathrm{~kJ}
\end{aligned}
$$

calculate the heat of solution of the hydronium ion:

$$
\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{g}) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})
$$

14.141 The electronic transition in Na from $3 p^{1}$ to $3 s^{1}$ gives rise to a bright yellow-orange emission at 589.2 nm . What is the energy of this transition?
14.142 Unlike other Group $2 \mathrm{~A}(2)$ metals, beryllium reacts like aluminum and zinc with concentrated aqueous base to release hydrogen gas and form oxoanions of formula $\mathrm{M}(\mathrm{OH})_{4}{ }^{n-}$. Write equations for the reactions of these three metals with NaOH .
14.143 The interhalogen IF undergoes the reaction depicted below ( I is purple and F is green):

(a) Write the balanced equation. (b) Name the interhalogen product. (c) What type of reaction is shown? (d) If each molecule of IF represents $2.50 \times 10^{-3} \mathrm{~mol}$, what mass of each product forms?
14.144 Cyclopropane $\left(\mathrm{C}_{3} \mathrm{H}_{6}\right)$, the smallest cyclic hydrocarbon, is reactive for the same reason white phosphorus is. Use bond properties and valence bond theory to explain its high reactivity. 14.145 Thionyl chloride $\left(\mathrm{SOCl}_{2}\right)$ is a sulfur oxohalide used industrially to dehydrate metal halide hydrates. (a) Write a balanced equation for its reaction with magnesium chloride hexahydrate, in which $\mathrm{SO}_{2}$ and HCl form along with the metal halide. (b) Draw a Lewis structure of $\mathrm{SOCl}_{2}$ with minimal formal charges.
14.146 The main reason alkali metal dihalides ( $\mathrm{MX}_{2}$ ) do not form is the high $\mathrm{IE}_{2}$ of the metal. (a) Why is $\mathrm{IE}_{2}$ so high for alkali metals? (b) The $\mathrm{IE}_{2}$ for Cs is $2255 \mathrm{~kJ} / \mathrm{mol}$, low enough for $\mathrm{CsF}_{2}$ to form exothermically ( $\Delta H_{\mathrm{f}}^{\circ}=-125 \mathrm{~kJ} / \mathrm{mol}$ ). This compound cannot be synthesized, however, because CsF forms with a much greater release of heat $\left(\Delta H_{\mathrm{f}}^{\circ}=-530 \mathrm{~kJ} / \mathrm{mol}\right)$. Thus, the breakdown of $\mathrm{CsF}_{2}$ to CsF happens readily. Write the equation for this breakdown, and calculate the heat of reaction per mole of CsF .
14.147 Semiconductors made from elements in Groups 3A(13) and $5 \mathrm{~A}(15)$ are typically prepared by direct reaction of the elements at high temperature. An engineer treats 32.5 g of molten gallium with 20.4 L of white phosphorus vapor at 515 K and 195 kPa . If purification losses are $7.2 \%$ by mass, how many grams of gallium phosphide will be prepared?
14.148 Two substances with empirical formula HNO are hyponitrous acid $(\mathcal{M}=62.04 \mathrm{~g} / \mathrm{mol})$ and nitroxyl $(\mathcal{M}=31.02 \mathrm{~g} / \mathrm{mol})$. (a) What is the molecular formula of each species?

Frb) Fer eachsees, draw the Lewis structure having the lowest formal charges. (Hint: Hyponitrous acid has an $\mathrm{N}=\mathrm{N}$ bond.)
(c) Predict the shape around the N atoms of each species.
(d) When hyponitrous acid loses two protons, it forms the hyponitrite ion. Draw cis and trans forms of this ion.
14.149 The species $\mathrm{CO}, \mathrm{CN}^{-}$, and $\mathrm{C}_{2}{ }^{2-}$ are isoelectronic.
(a) Draw their Lewis structures.
(b) Draw their MO diagrams (assume $2 s-2 p$ mixing, as in $\mathrm{N}_{2}$ ), and give the bond order and electron configuration for each.
14.150 The Ostwald process is a series of three reactions used for the industrial production of nitric acid from ammonia.
(a) Write a series of balanced equations for the Ostwald process.
(b) If NO is not recycled, how many moles of $\mathrm{NH}_{3}$ are consumed per mole of $\mathrm{HNO}_{3}$ produced?
(c) In a typical industrial unit, the process is very efficient, with a $96 \%$ yield for the first step. Assuming $100 \%$ yields for the subsequent steps, what volume of concentrated aqueous nitric acid ( $60 . \%$ by mass; $d=1.37 \mathrm{~g} / \mathrm{mL}$ ) can be prepared for each cubic meter of a gas mixture that is $90 . \%$ air and $10 . \% \mathrm{NH}_{3}$ by volume at the industrial conditions of 5.0 atm and $850 .{ }^{\circ} \mathrm{C}$ ?
14.151 Buckminsterfullerene $\left(\mathrm{C}_{60}\right)$ is a soccer-ball-shaped molecule with a C atom at each vertex. It crystallizes in a facecentered cubic unit cell that contains 240 C atoms and has a density of only $1.693 \mathrm{~g} / \mathrm{cm}^{3}$, less than half that of diamond. Calculate the volume and edge length of the unit cell, and suggest a reason for the low density despite the closest packing.
14.152 Perhaps surprisingly, some pure liquid interhalogens that contain fluorine have high electrical conductivity. The explanation is that one molecule transfers a fluoride ion to another molecule. Write the equation that would explain the high electrical conductivity of bromine trifluoride.
14.153 All common plant fertilizers contain nitrogen compounds. Determine the mass \% of N in (a) ammonia; (b) ammonium nitrate; (c) ammonium hydrogen phosphate.
14.154 Producer gas is a fuel formed by passing air over red-hot coke (amorphous carbon). What mass of a producer gas that consists of $25 \% \mathrm{CO}, 5.0 \% \mathrm{CO}_{2}$, and $70 . \% \mathrm{~N}_{2}$ by mass can be formed from 1.75 metric tons of coke, assuming an $87 \%$ yield?
14.155 Gaseous $\mathrm{F}_{2}$ reacts with water to form HF and $\mathrm{O}_{2}$. In NaOH solution, $\mathrm{F}_{2}$ forms $\mathrm{F}^{-}$, water, and oxygen difluoride $\left(\mathrm{OF}_{2}\right)$, a highly toxic gas and powerful oxidizing agent. The $\mathrm{OF}_{2}$ reacts with excess $\mathrm{OH}^{-}$, forming $\mathrm{O}_{2}$, water, and $\mathrm{F}^{-}$. (a) For each reaction, write a balanced equation, give the oxidation state of O in all compounds, and identify the oxidizing and reducing agents. (b) Draw a Lewis structure for $\mathrm{OF}_{2}$, and predict its shape.
14.156 What is a disproportionation reaction, and which of the following fit the description?
(a) $\mathrm{I}_{2}(s)+\mathrm{KI}(a q) \longrightarrow \mathrm{KI}_{3}(a q)$
(b) $2 \mathrm{ClO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{HClO}_{3}(a q)+\mathrm{HClO}_{2}(a q)$
(c) $\mathrm{Cl}_{2}(g)+2 \mathrm{NaOH}(a q) \longrightarrow$

$$
\mathrm{NaCl}(a q)+\mathrm{NaClO}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

(d) $\mathrm{NH}_{4} \mathrm{NO}_{2}(s) \longrightarrow \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)$
(e) $3 \mathrm{MnO}_{4}{ }^{2-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$

$$
2 \mathrm{MnO}_{4}^{-}(a q)+\mathrm{MnO}_{2}(s)+4 \mathrm{OH}^{-}(a q)
$$

(f) $3 \mathrm{AuCl}(s) \longrightarrow \mathrm{AuCl}_{3}(s)+2 \mathrm{Au}(s)$
14.157 Explain the following observations:
(a) In reactions with $\mathrm{Cl}_{2}$, phosphorus forms $\mathrm{PCl}_{5}$ in addition to the expected $\mathrm{PCl}_{3}$, but nitrogen forms only $\mathrm{NCl}_{3}$.
(b) Carbon tetrachloride is unreactive toward water, but silicon tetrachloride reacts rapidly and completely. (To give what?)
(c) The sulfur-oxygen bond in $\mathrm{SO}_{4}{ }^{2-}$ is shorter thameerpeted erDE an $\mathrm{S}-\mathrm{O}$ single bond.
(d) Chlorine forms $\mathrm{ClF}_{3}$ and $\mathrm{ClF}_{5}$, but $\mathrm{ClF}_{4}$ is unknown.
14.158 Which group(s) of the periodic table is (are) described by each of the following general statements?
(a) The elements form compounds of VSEPR class $\mathrm{AX}_{3} \mathrm{E}$.
(b) The free elements are strong oxidizing agents and form monatomic ions and oxoanions.
(c) The atoms form compounds by combining with two other atoms that donate one electron each.
(d) The free elements are strong reducing agents, show only one nonzero oxidation state, and form mainly ionic compounds.
(e) The elements can form stable compounds with only three bonds, but as a central atom, they can accept a pair of electrons from a fourth atom without expanding their valence shell.
(f) Only larger members of the group are chemically active.
14.159 Diiodine pentaoxide $\left(\mathrm{I}_{2} \mathrm{O}_{5}\right)$ was discovered by Joseph Gay-Lussac in 1813, but its structure was unknown until 1970! Like $\mathrm{Cl}_{2} \mathrm{O}_{7}$, it can be prepared by the dehydration-condensation of the corresponding oxoacid.
(a) Name the precursor oxoacid, write a reaction for formation of the oxide, and draw a likely Lewis structure.
(b) Data show that the bonds to the terminal O are shorter than the bonds to the bridging O . Why?
(c) $\mathrm{I}_{2} \mathrm{O}_{5}$ is one of the few chemicals that can oxidize CO rapidly and completely; elemental iodine forms in the process. Write a balanced equation for this reaction.
14.160 An important starting material for the manufacture of polyphosphazenes is the cyclic molecule $\left(\mathrm{NPCl}_{2}\right)_{3}$. The molecule has a symmetrical six-membered ring of alternating N and

P atoms, with the Cl atoms bonded to the P atoms. The nitrogenphosphorus bond length is significantly less than that expected for an N - P single bond.
(a) Draw a likely Lewis structure for the molecule.
(b) How many lone pairs of electrons do the ring atoms have?
(c) What is the order of the nitrogen-phosphorus bond?
14.161 Potassium fluotitanate $\left(\mathrm{K}_{2} \mathrm{TiF}_{6}\right)$, a starting material for producing other titanium salts, is made by dissolving titanium(IV) oxide in concentrated HF , adding aqueous KF , and then heating to dryness to drive off excess HF. The impure solid is recrystallized by dissolving in hot water and then cooling to $0^{\circ} \mathrm{C}$, which leaves excess KF in solution. For the reaction of 5.00 g of $\mathrm{TiO}_{2}, 250 . \mathrm{mL}$ of hot water is used to recrystallize the product. How many grams of purified $\mathrm{K}_{2} \mathrm{TiF}_{6}$ are obtained? (Solubility of $\mathrm{K}_{2} \mathrm{TiF}_{6}$ in water at $0^{\circ} \mathrm{C}$ is $0.60 \mathrm{~g} / 100 \mathrm{~mL}$.)
14.162 Bromine monofluoride ( BrF ) disproportionates to bromine gas and bromine tri- and pentafluorides. Use the following to find $\Delta H_{\mathrm{rxn}}^{\circ}$ for the decomposition of BrF to its elements:

$$
\begin{aligned}
3 \mathrm{BrF}(g) & \longrightarrow \mathrm{Br}_{2}(g)+\mathrm{BrF}_{3}(l) \\
5 \mathrm{BrF}(g) & \Delta H_{\mathrm{rxn}}=-125.3 \mathrm{~kJ} \\
\mathrm{Br}_{2}(g)+\mathrm{BrF}_{5}(l) & \Delta H_{\mathrm{rxn}}=-166.1 \mathrm{~kJ} \\
\mathrm{BrF}_{3}(l)+\mathrm{F}_{2}(g) \longrightarrow \mathrm{BrF}_{5}(l) & \Delta H_{\mathrm{rxn}}=-158.0 \mathrm{~kJ}
\end{aligned}
$$

14.163 Account for the following facts:
(a) $\mathrm{Ca}^{2+}$ and $\mathrm{Na}^{+}$have very nearly the same radii.
(b) $\mathrm{CaF}_{2}$ is insoluble in water, but NaF is quite soluble.
(c) Molten $\mathrm{BeCl}_{2}$ is a poor electrical conductor, whereas molten $\mathrm{CaCl}_{2}$ is an excellent one.
14.164 Cake alum (aluminum sulfate) is used as a flocculating agent in water purification. The "floc" is a gelatinous precipitate of aluninum hydroxide that carries small suspended particles and bacteria out of solution for removal by filtration.
(a) The hydroxide is formed by the reaction of the aluminum ion with water. Write the equation for this reaction.
(b) The acidity from this reaction is partially neutralized by the sulfate ion. Write an equation for this reaction.
14.165 Carbon tetrachloride is made by passing $\mathrm{Cl}_{2}$ in the presence of a catalyst through liquid $\mathrm{CS}_{2}$ near its boiling point. Disulfur dichloride $\left(\mathrm{S}_{2} \mathrm{Cl}_{2}\right)$ also forms, in addition to the byproducts $\mathrm{SCl}_{2}$ and $\mathrm{CCl}_{3} \mathrm{SCl}$. How many grams of $\mathrm{CS}_{2}$ reacted if excess $\mathrm{Cl}_{2}$ yielded 50.0 g of $\mathrm{CCl}_{4}$ and 0.500 g of $\mathrm{CCl}_{3} \mathrm{SCl}$ ? Is it possible to determine how much $\mathrm{S}_{2} \mathrm{Cl}_{2}$ and $\mathrm{SCl}_{2}$ also formed? Explain.
$14.166 \mathrm{H}_{2}$ may act as a reducing agent or an oxidizing agent, depending on the substance reacting with it. Using, in turn, sodium or chlorine as the other reactant, write balanced equations for the two reactions, and characterize the redox role of hydrogen.
$14.167 \mathrm{P}_{4}$ is prepared by heating phosphate rock [principally $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ ] with sand and coke:
$\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s)+\mathrm{SiO}_{2}(s)+\mathrm{C}(s) \longrightarrow$
$\mathrm{CaSiO}_{3}(s)+\mathrm{CO}(g)+\mathrm{P}_{4}(g)$ [unbalanced]
How many kilograms of phosphate rock are needed to produce 315 mol of $\mathrm{P}_{4}$, assuming that the conversion is $90 . \%$ efficient?
14.168 Element E forms an oxide of general structure A and a chloride of general structure B :

For the anion $\mathrm{EF}_{5}{ }^{-}$, what is (a) the molecular shape; (b) the hybridization of E; (c) the O.N. of E?
14.169 From its formula, one might expect CO to be quite polar, but its dipole moment is actually low (0.11 D). (a) Draw the Lewis structure for CO. (b) Calculate the formal charges. (c) Based on your answers to parts (a) and (b), explain why the dipole moment is so low.
14.170 In addition to $\mathrm{Al}_{2} \mathrm{Cl}_{6}$, aluminum forms other species with bridging halide ions to two aluminum atoms. One such species is the ion $\mathrm{Al}_{2} \mathrm{Cl}_{7}^{-}$. The ion is symmetrical, with a $180^{\circ}$ $\mathrm{Al}-\mathrm{Cl}-\mathrm{Al}$ bond angle.
(a) What orbitals does Al use to bond with the Cl atoms?
(b) What is the shape around each Al ?
(c) What is the hybridization of the central Cl ?
(d) What do the shape and hybridization suggest about the presence of lone pairs of electrons on the central Cl ?
14.171 When an alkaline earth carbonate is heated, it releases $\mathrm{CO}_{2}$, leaving the metal oxide. The temperature at which each Group $2 \mathrm{~A}(2)$ carbonate yields a $\mathrm{CO}_{2}$ partial pressure of 1 atm is

| Carbonate | Temperature $\left({ }^{\circ} \mathrm{C}\right)$ |
| :--- | :---: |
| $\mathrm{MgCO}_{3}$ | 542 |
| $\mathrm{CaCO}_{3}$ | 882 |
| $\mathrm{SrCO}_{3}$ | 1155 |
| $\mathrm{BaCO}_{3}$ | 1360 |

(a) Suggest a reason for this trend. (b) Mixtures of $\mathrm{CaCO}_{3}$ and MgO are used to absorb dissolved silicates from boiler water. How would you prepare a mixture of $\mathrm{CaCO}_{3}$ and MgO from dolomite, which contains $\mathrm{CaCO}_{3}$ and Aecu?gO PDE
14.172 The bond angles in the nitrite ion, nitrogen dioxide, and the nitronium ion $\left(\mathrm{NO}_{2}{ }^{+}\right)$are $115^{\circ}, 134^{\circ}$, and $180^{\circ}$, respectively. Explain these values using Lewis structures and VSEPR theory.
14.173 A common method for producing a gaseous hydride is to treat a salt containing the anion of the volatile hydride with a strong acid.
(a) Write an equation for each of the following examples: (1) the production of HF from $\mathrm{CaF}_{2}$; (2) the production of HCl from NaCl ; (3) the production of $\mathrm{H}_{2} \mathrm{~S}$ from FeS .
(b) In some cases even a weak acid such as water will suffice if the anion of the salt has a sufficiently strong attraction for protons. An example is the production of $\mathrm{PH}_{3}$ from $\mathrm{Ca}_{3} \mathrm{P}_{2}$ and water. Write the equation for this reaction.
(c) By analogy, predict the products and write the equation for the reaction of $\mathrm{Al}_{4} \mathrm{C}_{3}$ with water.
14.174 Chlorine trifluoride was formerly used in the production of uranium hexafluoride for the U.S. nuclear industry:

$$
\mathrm{U}(s)+3 \mathrm{ClF}_{3}(l) \longrightarrow \mathrm{UF}_{6}(l)+3 \mathrm{ClF}(g)
$$

How many grams of $\mathrm{UF}_{6}$ can form from 1.00 metric ton of uranium ore that is $1.55 \%$ by mass uranium and 12.75 L of chlorine trifluoride ( $d=1.88 \mathrm{~g} / \mathrm{mL}$ )?
14.175 Chlorine is used to make bleach solutions containing $5.25 \% \mathrm{NaClO}$ (by mass). Assuming $100 \%$ yield in the reaction producing NaClO from $\mathrm{Cl}_{2}$, how many liters of $\mathrm{Cl}_{2}(g)$ at STP will be needed to make 1000 . L of bleach solution ( $d=$ $1.07 \mathrm{~g} / \mathrm{mL})$ ?
14.176 The triatomic molecular ion $\mathrm{H}_{3}{ }^{+}$was first detected and characterized by J. J. Thomson using mass spectrometry. Use the bond energy of $\mathrm{H}_{2}(432 \mathrm{~kJ} / \mathrm{mol})$ and the proton affinity of $\mathrm{H}_{2}$ $\left(\mathrm{H}_{2}+\mathrm{H}^{+} \longrightarrow \mathrm{H}_{3}{ }^{+} ; \Delta H=-337 \mathrm{~kJ} / \mathrm{mol}\right)$ to calculate the heat of reaction for

$$
\mathrm{H}+\mathrm{H}+\mathrm{H}^{+} \longrightarrow \mathrm{H}_{3}^{+}
$$

14.177 An atomic hydrogen torch is used for cutting and welding thick sheets of metal. When $\mathrm{H}_{2}$ passes through an electric arc, the molecules decompose into atoms, which react with $\mathrm{O}_{2}$ at the end of the torch. Temperatures in excess of $5000^{\circ} \mathrm{C}$ are reached, which can melt all metals. Write equations for the breakdown of $\mathrm{H}_{2}$ to H atoms and for the subsequent overall reaction of the H atoms with oxygen. Use Appendix B to find the standard heat of each reaction per mole of product.
14.178 In aqueous hydrogen fluoride solution, an important species is the ion $\mathrm{HF}_{2}{ }^{-}$, which has the bonding arrangement $\mathrm{FHF}^{-}$. Draw the Lewis structure for this ion, and explain how it arises.
E14.29wherfothe following oxygen ions are paramagnetic: $\mathrm{O}^{+}, \mathrm{O}^{-}, \mathrm{O}^{2-}, \mathrm{O}^{2+}$ ?
14.180 Copper(II) hydrogen arsenite $\left(\mathrm{CuHAsO}_{3}\right)$ is a green pigment once used in wallpaper. In damp conditions, mold metabolizes this compound to trimethylarsine $\left[\left(\mathrm{CH}_{3}\right)_{3} \mathrm{As}\right]$, a highly toxic gas. (a) Calculate the mass percent of As in each compound. (b) How much $\mathrm{CuHAsO}_{3}$ must react to reach a toxic level in a room that measures $12.35 \mathrm{~m} \times 7.52 \mathrm{~m} \times 2.98 \mathrm{~m}$ (arsenic is toxic at $\left.0.50 \mathrm{mg} / \mathrm{m}^{3}\right)$ ?
14.181 Hydrogen peroxide can act as either an oxidizing agent or a reducing agent. (a) When $\mathrm{H}_{2} \mathrm{O}_{2}$ is treated with aqueous $\mathrm{KI}, \mathrm{I}_{2}$ forms. In which role is $\mathrm{H}_{2} \mathrm{O}_{2}$ acting? What is the oxygencontaining product formed? (b) When $\mathrm{H}_{2} \mathrm{O}_{2}$ is treated with aqueous $\mathrm{KMnO}_{4}$, the purple color of $\mathrm{MnO}_{4}{ }^{-}$disappears and a gas forms. In which role is $\mathrm{H}_{2} \mathrm{O}_{2}$ acting? What is the oxygencontaining product formed?

## 15

Herbal Essence This colored scanning electron micrograph of a freeze-fractured sage leaf reveals the round, reddish oil glands that secrete the numerous organic compounds responsible for the herb's taste and odor. Ultimately, the behavior of a living system is derived from that of its organic chemicals, which, as you'll see in this chapter, emerges from the behavior of the carbon atom.

The most remarkable chemical system known is a living cell. Through delicately controlled mechanisms, it oxidizes food for energy, maintains the concentrations of thousands of aqueous components, interacts continuously with its environment, synthesizes both simple and complex molecules, and even reproduces itself! For all our technological prowess, no human-made system even approaches the cell in its complexity and sheer elegance of function.

This amazing chemical machine consumes, creates, and consists largely of organic compounds. Except for a few inorganic salts and ever-present water, nearly everything you put into or on your body-food, medicine, cosmetics, and clothing-consists of organic compounds. Organic fuels warm our homes, cook our meals, and power our society. Major industries are devoted to producing organic compounds, such as polymers, pharmaceuticals, and insecticides.

What is an organic compound? Dictionaries define it as "a compound of carbon," but that definition is too general because it includes carbonates, cyanides, carbides, cyanates, and other carbon-containing ionic compounds that most chemists classify as inorganic. Here is a more specific definition: all organic compounds contain carbon, nearly always bonded to other carbons and hydrogen, and often to other elements.

The word organic has a biological connotation arising from a major misconception that stifled research into the chemistry of living systems for many decades. In the early $19^{\text {th }}$ century, many prominent thinkers believed that an unobservable spiritual energy, a "vital force," existed within the compounds of living things, making them impossible to synthesize and fundamentally different from compounds of the mineral world. This idea of vitalism was challenged in 1828, when the young German chemist Friedrich Wöhler heated ammonium cyanate, a "mineral-world" compound, and produced urea, a "living-world" compound:

$$
\mathrm{NH}_{4} \mathrm{OCN} \xrightarrow{\Delta} \mathrm{H}_{2} \mathrm{~N}-\stackrel{\mathrm{O}}{\mathrm{C}}-\mathrm{NH}_{2}
$$

Although Wöhler did not appreciate the significance of this reaction-he was more interested in the fact that two compounds can have the same molecular formula-his experiment is considered a key event in the origin of organic chemistry. Chemists soon synthesized methane, acetic acid, acetylene, and many other organic compounds from inorganic sources. Today, we know that the same chemical principles govern organic and inorganic systems because the behavior of a compound arises from the properties of its elements, no matter how marvelous that behavior may be.

IN THIS CHAPTER . . . We apply the text's central theme to the enormous field of organic chemistry to see how the structure and reactivity of organic molecules emerge naturally from the properties of their component atoms. First, we review the special atomic properties of carbon and see how they lead to the complex structure and reactivity of organic molecules. Next, we focus on writing and naming hydrocarbons as a prelude to naming other types of organic compounds. We classify the main types of organic reactions and apply them to various families of organic compounds. Finally, we extend these ideas to the giant molecules of commerce and life-synthetic and natural polymers.

### 15.1 THE SPECIAL NATURE OF CARBON AND THE CHARACTERISTICS OF ORGANIC MOLECULES

Although there is nothing mystical about organic molecules, their indispensable role in biology and industry leads us to ask if carbon has some extraordinary attributes that give it a special chemical "personality." Of course, each element

## Concepts \& Skills to Review before you study this chapter

- naming simple organic compounds; the functional-group concept (Section 2.8)
- constitutional isomerism (Section 3.2)
- $\Delta E N$ and bond polarity (Section 9.5)
- resonance structures (Section 10.1)
- VSEPR theory (Section 10.2)
- orbital hybridization (Section 11.1)
- $\sigma$ and $\pi$ bonding (Section 11.2)
- types of intermolecular forces and the shapes of biological macromolecules (Sections 12.3, 12.7, and 13.2)
- properties of the Period 2 elements (Section 14.2)
- properties of the Group 4A(14) elements (Section 14.6)

Organic Chemistry Is Enough to Drive One Mad The vitalists did not change their beliefs overnight. Indeed, organic compounds do seem different from inorganic compounds because of their complex structures and compositions. Imagine the consternation of the $19^{\text {th }}$-century chemist who was accustomed to studying compounds with formulas such as $\mathrm{CaCO}_{3}$, $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}$, and $\mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O}$ and then isolated white crystals from a gallstone and found their empirical formula to be $\mathrm{C}_{27} \mathrm{H}_{46} \mathrm{O}$ (cholesterol). Even Wöhler later said, "Organic chemistry . . . is enough to drive one mad. It gives me the impression of a primeval tropical forest, full of the most remarkable things, a monstrous and boundless thicket, with no way of escape, into which one may well dread to enter."

Figure 15.1 The position of carbon in the periodic table. Lying at the center of Period 2, carbon has an intermediate electronegativity (EN), and its position at the top of Group 4A(14) means it is relatively small. Other elements common in organic compounds are $\mathrm{H}, \mathrm{N}, \mathrm{O}, \mathrm{P}, \mathrm{S}$, and the halogens.
has its own specific properties, and carbon is no more unique than sodium, hafnium, or any other element. But the atomic properties of carbon do give it bonding capabilities beyond those of any other element, which in turn lead to the two obvious characteristics of organic molecules-structural complexity and chemical diversity.

## The Structural Complexity of Organic Molecules

Most organic molecules have much more complex structures than most inorganic molecules, and a quick review of carbon's atomic properties and bonding behavior shows why:

1. Electron configuration, electronegativity, and covalent bonding. Carbon's ground-state electron configuration of [He] $2 s^{2} 2 p^{2}$-four electrons more than He and four fewer than Ne -means that the formation of carbon ions is energetically impossible under ordinary conditions: to form a $\mathrm{C}^{4+}$ cation requires energy equal to the sum of $\mathrm{IE}_{1}$ through $\mathrm{IE}_{4}$, and to form a $\mathrm{C}^{4-}$ anion requires the sum of $\mathrm{EA}_{1}$ through $\mathrm{EA}_{4}$, the last three steps of which are endothermic. Carbon's position in the periodic table (Figure 15.1) and its electronegativity are midway between the most metallic and the most nonmetallic elements of Period 2: $\mathrm{Li}=1.0, \mathrm{C}=2.5, \mathrm{~F}=4.0$. Therefore, carbon shares electrons to attain a filled outer (valence) level, bonding covalently in all its elemental forms and compounds.
2. Bond properties, catenation, and molecular shape. The number and strength of carbon's bonds lead to its outstanding ability to catenate (form chains of atoms), which allows it to form a multitude of chemically and thermally stabla phairy aing, Pand pranchedzeompounds. Through the process of orbital hybridization (Section 11.1), carbon forms four bonds in virtually all its compounds, and they point in as many as four different directions. The small size of carbon allows close approach to another atom and thus greater orbital overlap, meaning that carbon forms relatively short, strong bonds. The $\mathrm{C}-\mathrm{C}$ bond is short enough to allow side-to-side overlap of half-filled, unhybridized $p$ orbitals and the formation of multiple bonds, which restrict rotation of attached groups (see Figure 11.13 , p. 421). These features add more possibilities for the molecular shapes of carbon compounds.
3. Molecular stability. Although silicon and several other elements also catenate, none can compete with carbon. Atomic and bonding properties confer three crucial differences between C and Si chains that explain why C chains are so stable and, therefore, so common:

- Atomic size and bond strength. As atomic size increases down Group 4A(14), bonds between identical atoms become longer and weaker. Thus, a $\mathrm{C}-\mathrm{C}$ bond ( $347 \mathrm{~kJ} / \mathrm{mol}$ ) is much stronger than an $\mathrm{Si}-\mathrm{Si}$ bond ( $226 \mathrm{~kJ} / \mathrm{mol}$ ).
- Relative heats of reaction. A $\mathrm{C}-\mathrm{C}$ bond $(347 \mathrm{~kJ} / \mathrm{mol})$ and a $\mathrm{C}-\mathrm{O}$ bond ( $358 \mathrm{~kJ} / \mathrm{mol}$ ) have nearly the same energy, so relatively little heat is released when a C chain reacts and one bond replaces the other. In contrast, an $\mathrm{Si}-\mathrm{O}$ bond ( $368 \mathrm{~kJ} / \mathrm{mol}$ ) is much stronger than an $\mathrm{Si}-\mathrm{Si}$ bond ( $226 \mathrm{~kJ} / \mathrm{mol}$ ), so a large quantity of heat is released when an Si chain reacts.
- Orbitals available for reaction. Unlike C, Si has low-energy $d$ orbitals that can be attacked (occupied) by the lone pairs of incoming reactants. Thus, for example, ethane $\left(\mathrm{CH}_{3}-\mathrm{CH}_{3}\right)$ is stable in water and does not react in air unless sparked, whereas disilane $\left(\mathrm{SiH}_{3}-\mathrm{SiH}_{3}\right)$ breaks down in water and ignites spontaneously in air.

## The Chemical Diversity of Organic Molecules

In addition to their elaborate geometries, organic compounds are noted for their sheer number and diverse chemical behavior. Look, for example, at the CRC Handbook of Chemistry and Physics, and you'll find that the number of organic compounds of carbon dwarfs the number of inorganic compounds of all the elements combined! Several million organic compounds are known, and thousands more are discovered or synthesized each year.

This incredible diversity is also founded on atomic and bonding behavior and is due to three interrelated factors:

1. Bonding to heteroatoms. Many organic compounds contain heteroatoms, atoms other than C or H . The most common heteroatoms are N and O , but $\mathrm{S}, \mathrm{P}$, and the halogens often occur, and organic compounds with other elements are known as well. Figure 15.2 shows that 23 different molecular structures are possible from various arrangements of four C atoms singly bonded to each other, the necessary number of H atoms, and just one O atom (either singly or doubly bonded).
2. Electron density and reactivity. Most reactions start-that is, a new bond begins to form-when a region of high electron density on one molecule meets a region of low electron density on another. These regions may be due to the presence of a multiple bond or to the partial charges that occur in carbon-heteroatom bonds. For example, consider four bonds commonly found in organic molecules:

- The C-C bond. When C is singly bonded to another C , as occurs in portions of nearly every organic molecule, the EN values are equal and the bond is nonpolar. Therefore, in general, $C-C$ bonds are unreactive.
- The $C-H$ bond. This bond, which also occurs in nearly every organic molecule, is very nearly nonpolar because it is short ( 109 pm ) and the EN values
 well.
- The $C-O$ bond. This bond, which occurs in many types of organic molecules, is highly polar ( $\Delta \mathrm{EN}=1.0$ ), with the O end of the bond electron rich and the C end electron poor. As a result of this imbalance in electron density, the $C-O$ bond is reactive and, given appropriate conditions, a reaction will occur there.
- Bonds to other heteroatoms. Even when a carbon-heteroatom bond has a small $\Delta \mathrm{EN}$, such as that for $\mathrm{C}-\mathrm{Br}(\Delta \mathrm{EN}=0.3)$, or none at all, as for $\mathrm{C}-\mathrm{S}$ $(\Delta \mathrm{EN}=0)$, heteroatoms like these are large, and so their bonds to carbon are long, weak, and thus reactive.

3. Nature of functional groups. One of the most important ideas in organic chemistry is that of the functional group, a specific combination of bonded atoms that reacts in a characteristic way, no matter what molecule it occurs in (we mentioned this idea briefly in Section 2.8). In nearly every case, the reaction of an organic compound takes place at the functional group. In fact, as you'll see, we often substitute a general symbol for the remainder of the molecule because it usually stays the same while the functional group reacts. Functional groups vary from carbon-carbon multiple bonds to several combinations of carbon-heteroatom bonds, and each has its own pattern of reactivity. A particular bond may be a functional group itself or part of one or more functional groups. For example, the $\mathrm{C}-\mathrm{O}$ bond occurs in four functional groups. We will discuss the reactivity of three of these groups in this chapter:

alcohol group

carboxylic acid group

ester group

Figure 15.2 The chemical diversity of organic compounds. Different arrangements of chains, branches, rings, and heteroatoms give rise to many structures. There are 23 different compounds possible from just four $C$ atoms joined by single bonds, one O atom, and the necessary H atoms.

## Section Summary

The structural complexity of organic compounds arises from carbon's small size, intermediate EN, four valence electrons, ability to form multiple bonds, and absence of $d$ orbitals in the valence level. These factors lead to chains, branches, and rings of C atoms joined by strong, chemically resistant bonds that point in as many as four directions from each C. - The chemical diversity of organic compounds arises from carbon's ability to bond to many other elements, including O and N , which creates polar bonds and greater reactivity. These factors lead to compounds that contain functional groups, specific portions of molecules that react in characteristic ways.

### 15.2 THE STRUCTURES AND CLASSES OF HYDROCARBONS

A fanciful, anatomical analogy can be made between an organic molecule and an animal. The carbon-carbon bonds form the skeleton: the longest continual chain is the backbone, and any branches are the limbs. Covering the skeleton is a skin of hydrogen atoms, with functional groups protruding at specific locations, like chemical fingers ready to grab an incoming reactant.

In this section, we "dissect" one group of compounds down to their skeletons and see how to name and draw them. Hydrocarbons, the simplest type of organic compound, are a large group of substances containing only H and C atoms. Some common fuels, such as natural gas and gasoline, are hydrocarbon mixtures. Hydrocarbons are also important feedstocks, precursor reactants used to make other compounds. Ethylene, acetylene, and benzene, for example, are feedstocks for hundreds of other substances.

## Carbonctreletons andily drogen Skins

Let's begin by examining the possible bonding arrangements of C atoms only (we'll leave off the H atoms at first) in simple skeletons without multiple bonds or rings. To distinguish different skeletons, focus on the arrangement of C atoms (that is, the successive linkages of one to another) and keep in mind that groups joined by single (sigma) bonds are relatively free to rotate (Section 11.2).

Structures with one, two, or three carbons can be arranged in only one way. Whether you draw three C atoms in a line or with a bend, the arrangement is the same. Four C atoms, however, have two possible arrangements - a four- C chain or a three-C chain with a one-C branch at the central C :

Even when we show the chain more realistically, with the bends due to the tetrahedral shape around the C atoms (as in the ball-and-stick models), the situation is the same. Notice that if the branch is added to either end of the three-C chain, it is simply a bend in a four-C chain, not a different arrangement. Similarly, if the branch points down instead of up, it represents the same arrangement because groups joined by single bonds rotate.

As the total number of C atoms increases, the number of different arrangements increases as well. Five C atoms have 3 possible arrangements; 6 C atoms can be arranged in 5 ways, 7 C atoms in 9 ways, 10 C atoms in 75 ways, and
A C-C-C-C-C
B $\mathrm{C}=\mathrm{C}-\mathrm{C}-\mathrm{C}-\mathrm{C}$
$\mathrm{C}-\mathrm{C}=\mathrm{C}-\mathrm{C}-\mathrm{C}$

C

Figure 15.3 Some five-carbon skeletons. A, Three five-C skeletons are possible with only single bonds. B, Five more skeletons are possible with one $\mathrm{C}=\mathrm{C}$ bond present. C, Five more skeletons are possible with one ring present. Even more would be possible with a ring and a double bond.

20 C atoms in more than 300,000 ways! If we include multiple bonds and rings, the number of arrangements increases further. For example, including one $\mathrm{C}=\mathrm{C}$ bond in the five-C skeletons creates 5 more arrangements, and including one ring creates 5 more (Figure 15.3).

When determining the number of different skeletons for a given number of C atoms, remember that

- Each C atom can form a maximum of four single bonds, or two single and one double bond, or one single and one triple bond.
- The arrangement of C atoms dettrines the sketron, sorastiaichtchain and a bent chain represent the same skeleton.
- Groups joined by single bonds can rotate, so a branch pointing down is the same as one pointing up. (Recall that a double bond restricts rotation.)

If we put a hydrogen "skin" on a carbon skeleton, we obtain a hydrocarbon. Figure 15.4 shows that the skeleton has the correct number of H atoms when each C has four bonds. Sample Problem 15.1 provides practice drawing hydrocarbons.

A C atom single-bonded to four other atoms is already fully bonded (no H atoms).

A C atom single-bonded to two other atoms gets two H atoms.

A double-bonded C atom is treated as if it were bonded to two other atoms.

A C atom single-bonded to three other atoms gets one H atom.

A double- and single-bonded C atom or a triple-bonded C atom is treated as if it were bonded to three other atoms.

Figure 15.4 Adding the H -atom skin to the C -atom skeleton. In a hydrocarbon molecule, each carbon atom bonds to as many hydrogen atoms as needed to give the carbon a total of four bonds.

## SAMPLE PROBLEM 15.1 Drawing Hydrocarbons

PROBLEM Draw structures that have different atom arrangements for hydrocarbons with:
(a) Six C atoms, no multiple bonds, and no rings
(b) Four C atoms, one double bond, and no rings
(c) Four C atoms, no multiple bonds, and one ring

PLAN In each case, we draw the longest carbon chain first and then work down to smaller chains with branches at different points along them. The process typically involves trial and error. Then, we add H atoms to give each C a total of four bonds.
SOLUTION (a) Compounds with six C atoms:

5-C chains:

(b) Compounds with four C atoms and one double bond:

4-C chains:

3-C chain:

(c) Compounds with four C atoms and one ring:

CHECK Be sure each skeleton has the correct number of C atoms, multiple bonds, and/or rings, and no arrangements are repeated or omitted; remember a double bond counts as two bonds.
COMMENT Avoid some common mistakes:
In (a): $\mathrm{C}-\mathrm{C}-\mathrm{C}-\mathrm{C}-\mathrm{C}$ is the same skeleton as

is the same skeleton as

In (b): $\mathrm{C}-\mathrm{C}-\mathrm{C}=\mathrm{C}$ is the same skeleton as $\mathrm{C}=\mathrm{C}-\mathrm{C}-\mathrm{C}$
The double bond restricts rotation, so, in addition to the cis form shown in part (b), another possibility is the trans form:

(We discuss cis-trans isomers fully later in this section.)

Also, there are too many bonds to one C in

FOLLOW-UP PROBLEM 15.1 Draw all hydrocarbons that have different atom arrangements with:
(a) Seven C atoms, no multiple bonds, and no rings (nine arrangements)
(b) Five C atoms, one triple bond, and no rings (three arrangements)

Hydrocarbons can be classified into four main groups. In the remainder of this section, we examine the names and some structural features and physical properties of each group. Later, we discuss the chemical behavior of the hydrocarbons.

## Alkanes: Hydrocarbons with Only Single Bonds

A hydrocarbon that contains only single bonds is an alkane (general formula $\mathbf{C}_{n} \mathbf{H}_{2 n+2}$, where $n$ is a positive integer). For example, if $n=5$, the formula is $\mathrm{C}_{5} \mathrm{H}_{[(2 \times 5)+2]}$, or $\mathrm{C}_{5} \mathrm{H}_{12}$. The alkanes comprise a homologous series, one in which
 alkane, each C is $s p^{3}$ hybridized. Because each C is bonded to the maximum number of other atoms $(\mathrm{C}$ or H$)$, alkanes are referred to as saturated hydrocarbons.
Naming Alkanes You learned how to name simple alkanes in Section 2.8. Here we discuss general rules for naming any alkane and, by extension, other organic compounds as well. The key point is that each chain, branch, or ring has a name based on the number of $C$ atoms. The name of a compound has three portions:
prefix + ROOT + suffix

- Root: The root tells the number of C atoms in the longest continuous chain in the molecule. The roots for the ten smallest alkanes are shown in Table 15.1. As you can see, there are special roots for compounds of one to four C atoms; roots of longer chains are based on Greek numbers.
- Suffix: The suffix tells the type of organic compound the molecule represents; that is, it identifies the key functional group the molecule possesses. The suffix is placed after the root.
- Prefix: Each prefix identifies a group attached to the main chain and the number of the carbon to which it is attached. Prefixes identifying hydrocarbon branches are the same as root names (Table 15.1) but have $-y l$ as their ending. Each prefix is placed before the root.

For example, in the name 2-methylbutane, 2-methyl- is the prefix (a one-carbon branch is attached to C-2 of the main chain), -but- is the root (the main chain has four C atoms), and -ane is the suffix (the compound is an alkane).

To obtain the systematic name of a compound,

1. Name the longest chain (root).
2. Add the compound type (suffix).
3. Name any branches (prefix).

Table 15.1 Numerical Roots for Carbon Chains and Branches

| Roots | Number of <br> C Atoms |
| :--- | :---: |
| meth- | 1 |
| eth- | 2 |
| prop- | 3 |
| but- | 4 |
| pent- | 5 |
| hex- | 6 |
| hept- | 7 |
| oct- | 8 |
| non- | 9 |
| dec- | 10 |

Table 15.2 Rules for Naming an Organic Compound

1. Naming the longest chain (root)
(a) Find the longest continuous chain of C atoms.
(b) Select the root that corresponds to the number of C atoms in this chain.

6 carbons $\Longrightarrow$ hex-
2. Naming the compound type (suffix)
(a) For alkanes, add the suffix -ane to the chain root. (Other suffixes appear in Table 15.5 with their functional group and compound type.)
(b) If the chain forms a ring, the name is preceded by cyclo-.
3. Naming the branches (prefixes) (If the compound has no branches, the name consists of the root and suffix.)
(a) Each branch name consists of a subroot (number of C atoms) and the ending $-y l$ to signify that it is not part of the main chain.
(b) Branch names precede the chain name. When two or more branches are present, their names appear in alphabetical order.
(c) To specify where the branch occurs along the chain, number the main-chain C atoms consecutively, starting at the end closer to a branch, to achieve the lowest numbers for the branches. Precede each branch name with the number of the main-chain C to which that branch is attached.

ethylmethylhexane

3-ethyl-2-methylhexane

Figure 15.5 Ways of depicting an alkane.

Table 15.2 presents the rules for naming any organic compound and applies them to an alkane component of gasoline. Other organic compounds are named with a variety of other prefixes and suffixes (see Table 15.5, p. 651). In addition to these syturanty

Depicting Alkanes with Formulas and Models Chemists have several ways to depict organic compounds. Expanded, condensed, and carbon-skeleton formulas are easy to draw; ball-and-stick and space-filling models show the actual shapes.

The expanded formula shows each atom and bond. One type of condensed formula groups each C atom with its H atoms. Carbon-skeleton formulas show only carbon-carbon bonds and appear as zig-zag lines, often with branches. Each end or bend of a zig-zag line or branch represents a $C$ atom attached to the number of $H$ atoms that gives it a total of four bonds:

2,3-dimethylbutane

Figure 15.5 shows these types of formulas, together with ball-and-stick and space-filling models, of the compound named in Table 15.2.

Expanded formula

Carbon-skeleton formula

Ball-and-stick model

Space-filling model

A Cyclopropane

C Cyclopentane

D Cyclohexane

Figure 15.6 Depicting cycloalkanes. Cycloalkanes are usually drawn as regular polygons. Each side is a C-C bond, and each corner represents a C atom with its required number of H atoms. The expanded formulas show each bond in the molecule. The ball-and-stick and spacefilling models show that, except for cyclopropane, the rings are potıplanar, These conformations minimize electron repulsions between adjacent Hatoms. Cyctohexane (D)is showninits more stable chair conformation.

Cyclic Hydrocarbons A cyclic hydrocarbon contains one or more rings in its structure. When a straight-chain alkane $\left(\mathrm{C}_{n} \mathrm{H}_{2 n+2}\right)$ forms a ring, two H atoms are lost as the $\mathrm{C}-\mathrm{C}$ bond forms to join the two ends of the chain. Thus, cycloalkanes have the general formula $\mathrm{C}_{n} \mathrm{H}_{2 n}$. Cyclic hydrocarbons are often drawn with carbon-skeleton formulas, as shown at the top of Figure 15.6. Except for threecarbon rings, cycloalkanes are nonplanar. This structural feature arises from the tetrahedral shape around each C atom and the need to minimize electron repulsions between adjacent H atoms. As a result, orbital overlap of adjacent C atoms is maximized. The most stable form of cyclohexane, called the chair conformation, is shown in Figure 15.6D.

## Constitutional Isomerism and the Physical Properties of Alkanes

Recall from Section 3.2 that two or more compounds with the same molecular formula but different properties are called isomers. Those with different arrangements of bonded atoms are constitutional (or structural) isomers; alkanes with the same number of C atoms but different skeletons are examples. The smallest alkane to exhibit constitutional isomerism has four C atoms: two different compounds have the formula $\mathrm{C}_{4} \mathrm{H}_{10}$, as shown in Table 15.3, on page 638. The unbranched one is butane (common name, $n$-butane; $n$ - stands for "normal," or having a straight chain), and the other is 2 -methylpropane (common name, isobutane). Similarly, three compounds have the formula $\mathrm{C}_{5} \mathrm{H}_{12}$ (shown in Table 15.3). The unbranched isomer is pentane (common name, $n$-pentane); the one with a

| Systematic Name (Common Name) | $\begin{array}{ll} & \text { Condensed and } \\ \text { Expanded Formula } & \text { Skeleton Formulas }\end{array}$ | Space-Filling Model | Density $(\mathrm{g} / \mathrm{mL})$ | Boiling <br> Point ( ${ }^{\circ} \mathrm{C}$ ) |

| 2-Methylbutane (isopentane) |   |  | 0.620 | 27.8 |
| 2,2-Dimethylpropane (neopentane) |  |  | 0.614 | 9.5 |

methyl group at $\mathrm{C}-2$ of a four-C chain is 2-methylbutane (common name, isopentane). The third isomer has two methyl branches on $\mathrm{C}-2$ of a three- C chain, so its name is 2,2-dimethylpropane (common name, neopentane).

Because alkanes are nearly nonpolar, we expect their physical properties to be determined by dispersion forces, and the boiling points in Table 15.3 certainly bear this out. The four-C alkanes boil lower than the five-C compounds. Moreover, within each group of isomers, the more spherical member (isobutane or neopentane) boils lower than the more elongated one ( $n$-butane or $n$-pentane). As you saw in Chapter 12, this trend occurs because a spherical shape leads to less intermolecular contact, and thus lower total dispersion forces, than does an elongated shape.

A particularly clear example of the effect of dispersion forces on physical properties occurs among the unbranched alkanes ( $n$-alkanes). Among these compounds, boiling points increase steadily with chain length: the longer the chain, the greater the intermolecular contact, the stronger the dispersion forces, and the higher the boiling point (Figure 15.7). Pentane (five C atoms) is the smallest $n$-alkane that exists as a liquid at room temperature. The solubility of alkanes, and of all hydrocarbons, is easy to predict from the like-dissolves-like rule (Section 13.1). Alkanes are miscible in each other and in other nonpolar solvents, such as benzene, but are nearly insoluble in water. The solubility of pentane in water, for example, is only $0.36 \mathrm{~g} / \mathrm{L}$ at room temperature.

Figure 15.7 Boiling points of the first 10 unbranched alkanes. Boiling point increases smoothly with chain length because dispersion forces increase. Each entry includes the name, molecular
formula, molar mass ( $\mathcal{M}$, in $\mathrm{g} / \mathrm{mol}$ ), condensed formula, space-filling model, and boiling point at 1 atm pressure.

## Chiral Molecules and Optical Isomerism

Another type of isomerism exhibited by some alkanes and many other organic (as well as some inorganic) compounds is called stereoisomerism. Stereoisomers are molecules with the same arrangement of atoms but different orientations of groups in space. Optical isomerism is one Apo a dereoisprism: Fhenlywa gbieat qre mirror images of each other and cannot be superimposed, they are optical isomers, also called enantiomers. To use a familiar example, your right hand is an optical isomer of your left. Look at your right hand in a mirror, and you will see that the image is identical to your left hand (Figure 15.8). No matter how you twist your arms around, however, your hands cannot lie on top of each other with all parts superimposed. They are not superimposable because each is asymmetric: there is no plane of symmetry that divides your hand into two identical parts.

An asymmetric molecule is called chiral (Greek cheir, "hand"). Typically, an organic molecule is chiral if it contains a carbon atom that is bonded to four different groups. This C atom is called a chiral center or an asymmetric carbon. In 3-methylhexane, for example, $\mathrm{C}-3$ is a chiral center because it is bonded to four different groups: $\mathrm{H}-, \mathrm{CH}_{3}-, \mathrm{CH}_{3}-\mathrm{CH}_{2}-$, and $\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-$ (Figure 15.9A). Like your two hands, the two forms are mirror images and cannot be superimposed on each other: when two of the groups are superimposed, the other two are opposite each other. Thus, the two forms are optical isomers. The central C atom in the amino acid alanine is also a chiral center (Figure 15.9B).

B Optical isomers of alanine

Figure 15.8 An analogy for optical isomers. The reflection of your right hand looks like your left hand. Each hand is asymmetric, so you cannot superimpose them with your palms facing in the same direction.

Figure 15.9 Two chiral molecules. A,
3-Methylhexane is chiral because $\mathrm{C}-3$ is bonded to four different groups. These two models are optical isomers (enantiomers). B, The central $\mathbf{C}$ in the amino acid alanine is also bonded to four different groups.

Figure 15.10 The rotation of planepolarized light by an optically active substance. The source emits light oscillating in all planes. When the light passes through the first polarizing filter, light oscillating in only one plane emerges. The plane-polarized light enters the sample compartment, which contains a known concentration of an optical isomer, and the plane rotates as the light passes through the solution. For the experimenter to see the light, it must pass through a second polarizing filter (called the analyzer), which is attached to a movable ring that is calibrated in degrees and measures the angle of rotation.

Chiral Medicines Many drugs are chiral molecules of which one optical isomer is biologically active and the other has either a different type of activity or none at all. Naproxen, the pain reliever and antiinflammatory agent, is an example; one isomer (see the model) is active as an anti-arthritic agent, and the other is a potent liver toxin that must be removed from the mixture during synthesis. The notorious drug thalidomide is another example. One optical isomer is active against depression, whereas the other causes fetal mutations and deaths. Tragically, the drug was sold in the 1950s as the racemic mixture and caused limb malformations in many children whose mothers had it prescribed to relieve "morning sickness" during pregnancy.

Unlike constitutional isomers, optical isomers are identical in all but two respects:

1. In their physical properties, optical isomers differ only in the direction that each isomer rotates the plane of polarized light. A polarimeter is used to measure the angle that the plane is rotated (Figure 15.10). A beam of light consists of waves that oscillate in all planes. A polarizing filter blocks all waves except those in one plane, so the light emerging through the filter is plane-polarized. An optical isomer is optically active because it rotates the plane of this polarized light. (Liquid crystal displays incorporate polarizing filters and optically active compounds; see Figure 12.45, p. 481.) The dextrorotatory isomer (designated $d$ or + ) rotates the plane of light clockwise; the levorotatory isomer (designated $l$ or - ) is the mirror image of the $d$ isomer and rotates the plane counterclockwise. An equimolar mixture of the two isomers (called a racemic mixture) does not rotate theplane atrlitrbequselthe dextrorgtation cancels the levorotation. The specific rotation is a characteristic, measurable property of the isomer at a certain temperature, concentration, and wavelength of light.
2. In their chemical properties, optical isomers differ only in a chiral (asymmetric) chemical environment, one that distinguishes "right-handed" from "lefthanded" molecules. As an analogy, your right hand fits well in your right glove but not in your left glove. Typically, one isomer of an optically active reactant is added to a mixture of optical isomers of another compound. The products of the reaction have different properties and can be separated. For example, when the anion $d$-lactate is added to a mixture of the cationic forms $d$-alanine and $l$-alanine, the $d$ isomer of alanine crystallizes as the $d$-lactate/ $d$-alanine salt, but the $d$ lactate $/ l$-alanine salt is more soluble and remains in solution.

Optical isomerism plays a vital role in living cells. Nearly all carbohydrates and amino acids are optically active, but only one of the isomers is biologically usable. For example, $d$-glucose is metabolized for energy, but $l$-glucose is excreted unused. Similarly, $l$-alanine is incorporated naturally into proteins, but $d$-alanine is not. The organism distinguishes one optical isomer from the other through its enzymes, large molecules that speed virtually every reaction in the cell by binding to the reactants. A specific portion of the enzyme provides the asymmetric environment, so only one of the isomers can bind there and undergo reaction (Figure 15.11).

## Alkenes: Hydrocarbons with Double Bonds

A hydrocarbon that contains at least one $\mathrm{C}=\mathrm{C}$ bond is called an alkene. With two H atoms removed to make the double bond, alkenes have the general formula $\mathbf{C}_{n} \mathbf{H}_{2 n}$. The double-bonded C atoms are $s p^{2}$ hybridized. Because their carbon atoms are bonded to fewer than the maximum of four atoms each, alkenes are considered unsaturated hydrocarbons.

Alkene names differ from those of alkanes in two respects:

1. The main chain (root) must contain both C atoms of the double bond, even if it is not the longest chain. The chain is numbered from the end closer to the $\mathrm{C}=\mathrm{C}$ bond, and the position of the bond is indicated by the number of the first C atom in it.
2. The suffix for alkenes is -ene.

For example, there are three four-C alkenes $\left(\mathrm{C}_{4} \mathrm{H}_{8}\right)$, two unbranched and one branched (see Sample Problem 15.1b). The branched isomer is 2-methylpropene; the unbranched isomer with the $\mathrm{C}=\mathrm{C}$ bond between $\mathrm{C}-1$ and $\mathrm{C}-2$ is 1-butene; the unbranched isomer with the $\mathrm{C}=\mathrm{C}$ bond between $\mathrm{C}-2$ and $\mathrm{C}-3$ is 2-butene. As you'll see next, there are two isomers of 2-butene, but they are of a different sort (discussed briefly in Sections 10.3 and 11.2).

The $\mathbf{C}=\mathbf{C}$ Bond and Geometric (cis-trans) Isomerism There are two major structural differences between alkenes and alkanes. First, alkanes have a tetrahedral geometry (bond angles of $\sim 109.5^{\circ}$ ) around each C atom, whereas the double-bonded C atoms in alkenes are trigonal planar $\left(\sim 120^{\circ}\right)$. Second, the $\mathrm{C}-\mathrm{C}$ bond allows rotation of bonded groups, so the atoms in an alkane continually change their relative positions. In contrast, the $\pi$ bond of the $\mathrm{C}=\mathrm{C}$ bond restricts rotation, which fixes the relative positions of the atoms bonded to it.

This rotational restriction leads to another type of stereoisomerism. Geometric isomers (also called cis-trans isomers) have different orientations of groups around a double bond (or similar structural feature). Table 15.4 shows the two geometric isomers of 2-butene (also see Comment, Sample Problem 15.1). One isomer, cis-2-butene, has the $\mathrm{CH}_{3}$ groups on the same side of the $\mathrm{C}=\mathrm{C}$ bond, whereas the other isomer, trans-2-butene, has them-on opposite sides of the $\mathrm{C}=\mathrm{C}$ bond. In general, the cis isomer has the qarger portions of the main chatn (in this case, two $\mathrm{CH}_{3}$ groups) on the same side of the double bond, and the trans isomer has them on opposite sides. (Cis-trans isomerism also occurs in many transition metal compounds, which have a different structural feature that restricts rotation, as we discuss in Chapter 23.) For a molecule to have geometric isomers, each $C$ atom in the $C=C$ bond must be bonded to two different groups. Like other isomers, geometric isomers have different properties. Note in Table 15.4 that the two 2-butenes differ in molecular shape and physical properties. The cis isomer has a bend in the chain that the trans isomer lacks. In Chapters 10 and 12, you saw how such a difference affects molecular polarity and physical properties, which arise from differing strengths of intermolecular attractions. The upcoming Chemical Connections essay shows how this simple difference in geometry has profound effects in biological systems as well.

| Systematic Name | Condensed and Skeleton Formulas | Space-Filling Model | Density (g/mL) | Boiling <br> Point ( ${ }^{\circ} \mathrm{C}$ ) |
| :---: | :---: | :---: | :---: | :---: |
| cis-2-Butene |   |  | 0.621 | 3.7 |
| trans-2-Butene |  |  | 0.604 | 0.9 |

Figure 15.11 The binding site of an enzyme. Organisms can utilize only one of a pair of optical isomers because their enzymes have binding sites with shapes that are chiral (asymmetric). The shape of the mirror image of this molecule does not allow it to bind at this site.

# Chemical Connections to Sensory Physiology 

## Geometric Isomers and the Chemistry of Vision

0f all our senses, sight provides the most information about the external world. Light bouncing off objects enters the lens of the eye and is focused on the retina. From there, molecular signals are converted to mechanical signals and then to electrical signals that are transmitted to the brain. This remarkable sequence is one of the few physiological processes that we understand thoroughly at the molecular level. The first step relies on the different shapes of geometric isomers.

The molecule responsible for receiving the light energy is retinal. It is derived from retinol (vitamin A), which we obtain mostly from $\beta$-carotene in yellow and green vegetables. Retinal is a $20-\mathrm{C}$ compound consisting of a $15-\mathrm{C}$ chain and five $1-\mathrm{C}$ branches. As you can see from the ball-and-stick model in Figure B15.1, the chain includes five $\mathrm{C}=\mathrm{C}$ bonds, a six- C ring at one end, and a $\mathrm{C}=\mathrm{O}$ bond at the other. There are two biologically occurring isomers of retinal. The all-trans isomer, shown on the right, has a trans orientation around all five double bonds. The 11-cis isomer, shown on the left, has a cis orientation around the $\mathrm{C}=\mathrm{C}$ bond between C-11 and C-12. Note the significant difference in shape between the two isomers.

Certain cells of the retina are densely packed with rhodopsin, which consists of the relatively small 11-cis-retinal covalently bonded to a large protein. The initial chemical event in vision occurs when rhodopsin absorbs a photon of visible light. The energy
of visible photons (between 165 and $293 \mathrm{~kJ} / \mathrm{mol}$ ) lies in the range needed to break a $\mathrm{C}=\mathrm{C} \pi$ bond ( $\sim 250 \mathrm{~kJ} / \mathrm{mol}$ ). Retinal is bonded to the protein in such a way that the 11-cis $\pi$ bond is the most susceptible to breakage. The photon is absorbed in a few trillionths of a second, the cis $\pi$ bond breaks, the groups attached to the intact $\sigma$ bond rotate, and a $\pi$ bond re-forms to produce all-trans-retinal in another few millionths of a second. In effect, light energy is converted into the mechanical energy of the moving molecular chain.

This rapid and relatively large change in the shape of retinal causes the protein portion of rhodopsin to change shape as wella process that breaks the bond between the protein portion and retinal. The change in protein shape triggers a flow of ions into the retina cells, initiating electrical impulses to the optic nerve, which conducts them to the brain. Meanwhile, the free all-trans-retinal diffuses away and is changed back to the cis form, which then binds to the protein portion again.

Retinal must be ideally suited to its function because it has been selected through evolution as a photon absorber in organisms as different as purple bacteria, mollusks, insects, and vertebrates. The features that make it the perfect choice are its strong absorption in the visible region, the efficiency with which light converts the cis to the trans form, and the large structural change it undergoes when this takes place.

## Apago PDF Enhancer

Figure B15.1 The initial chemical event in vision. In rhodopsin, the geometric isomer 11-cis-retinal is bonded to (shown here as lying on) a large protein. A photon absorbed by the retinal breaks the 11-cis $\pi$ bond. The two parts of the retinal chain rotate around the $\sigma$ bond
(shown in circle), and the $\pi$ bond forms again but with a trans orientation. This change in the shape of retinal changes the shape of the protein, causing it to release the all-trans-retinal.

## Alkynes: Hydrocarbons with Triple Bonds

Hydrocarbons that contain at least one $\mathrm{C} \equiv \mathrm{C}$ bond are called alkynes. Their general formula is $\mathbf{C}_{\boldsymbol{n}} \mathbf{H}_{\mathbf{2 n - 2}}$ because they have two H atoms fewer than alkenes with the same number of carbons. Because a carbon in a $\mathrm{C} \equiv \mathrm{C}$ bond can bond to only one other atom, the geometry around each C atom is linear $\left(180^{\circ}\right)$ : each C is $s p$ hybridized. Alkynes are named in the same way as alkenes, except that the suffix is -yne. Because of their localized $\pi$ electrons, $\mathrm{C}=\mathrm{C}$ and $\mathrm{C} \equiv \mathrm{C}$ bonds are electron rich and act as functional groups. Thus, alkenes and alkynes are much more reactive than alkanes, as we'll discuss in Section 15.4.

## SAMPLE PROBLEM 15.2 Naming Alkanes, Alkenes, and Alkynes

PROBLEM Give the systematic name for each of the following, indicate the chiral center in part (d), and draw two geometric isomers for part (e):

(c)

PLAN For (a) to (c), we refer to Table 15.2, p. 636. We first name the longest chain (root+ -ane). Then we find the lowest branch numbers by counting C atoms from the end closer to a branch. Finally, we name each branch (root- $+-y l$ ) and put the names alphabetically before the chain name. For (d) and (e), the longest chain that includes the multiple bond is numbered from the end closer to it. For (d), the chiral center is the C atom bonded to four different groups. In (e), the cis isomer has larger groups on the same side of the double bond, and the trans isomer has them on opposite sides.

## SOLUTION

(a)

## 2,2-dimethylbutane

When a type of branch appears more than once, we group the chain numbers and indicate the number of branches with a numerical prefix, such as 2,2-dimethyl.
(b)

3,4-dimethylhexane
In this case, we can number the chain from either end because the branches are the same and are attached to the two central C atoms.
(d)

3-methyl-1-pentene
(e)

cis-2,3-dimethyl-3-hexene
(c)

## 1-ethyl-2-methylcyclopentane

We number the ring C atoms so that a branch is attached to C-1.

trans-2,3-dimethyl-3-hexene

CHECK A good check (and excellent practice) is to reverse the process by drawing structures for the names to see if you come up with the structures given in the problem.
COMMENT In part (b), C-3 and C-4 are chiral centers, as are $\mathrm{C}-1$ and $\mathrm{C}-2$ in part (c). However, in (b) the molecule is not chiral: it has a plane of symmetry between C-3 and C-4, so half of the molecule rotates light opposite to the other half. Avoid these common mistakes: In (b), 2-ethyl-3-methylpentane is wrong: the longest chain is hexane. In (c), 1-methyl-2-ethylcyclopentane is wrong: the branch names appear alphabetically.
FOLLOW-UP PROBLEM 15.2 Draw condensed formulas for the following compounds: (a) 3-ethyl-3-methyloctane; (b) 1-ethyl-3-propylcyclohexane (also draw a carbonskeleton formula for this compound); (c) 3,3-diethyl-1-hexyne; (d) trans-3-methyl-3-heptene.

Figure 15.12 Representations of ben-
zene. A, Benzene is often drawn with two resonance forms, showing alternating single and double bonds in different positions. The molecule is more correctly depicted as the resonance hybrid, with the delocalized electrons shown as an unbroken or dashed circle. B, The delocalized $\pi$ cloud and the $\sigma$-bond plane of the benzene ring.

## Aromatic Hydrocarbons: Cyclic Molecules with Delocalized $\pi$ Electrons

Unlike the cycloalkanes, aromatic hydrocarbons are planar molecules, usually with one or more rings of six C atoms, and are often drawn with alternating single and double bonds. As you learned for benzene (Section 10.1), however, all the ring bonds are identical, with values of length and strength between those of a $\mathrm{C}-\mathrm{C}$ and a $\mathrm{C}=\mathrm{C}$ bond. To indicate this, benzene is also shown as a resonance hybrid, with a circle (or dashed circle) representing the delocalized character of the $\pi$ electrons (Figure 15.12A). An orbital picture shows the two lobes of the delocalized $\pi$ cloud above and below the hexagonal plane of the $\sigma$-bonded C atoms (Figure 15.12B).

AThe efsemationning of Bimple arematic compounds is quite straightforward. Usually, benzene is the parent compound, and attached groups, or substituents, are named as prefixes. However, many common names are still in use. For example, benzene with one methyl group attached is systematically named methylbenzene but is better known by its common name, toluene. With only one substituent present in toluene, we do not number the ring C atoms; when two or more groups are attached, however, we number in such a way that one of the groups is attached to ring $\mathrm{C}-1$. Thus, toluene and the three structural isomers with two methyl groups attached are

In common names, the positions of two groups are indicated by $o$ - (ortho) for groups on adjacent ring C atoms, $m$ - (meta) for groups separated by one ring C atom, and $p$ - (para) for groups on opposite ring C atoms. The dimethylbenzenes (commonly known as xylenes) are important solvents and feedstocks for polyester fibers and dyes. (See the margin note on page 645.)

The number of isomers increases with more than two attached groups. For example, there are six isomers for a compound with one methyl and three nitro
$\left(-\mathrm{NO}_{2}\right)$ groups attached to a benzene ring; the explosive TNT, shown below, is only one:

2,4,6-trinitromethylbenzene (trinitrot oluene, TNT)

One of the most important methods for determining the structures of organic molecules is discussed in the upcoming Tools of the Laboratory essay.

## Variations on a Theme: Catenated Inorganic Hydrides

In short discussions called Variations on a Theme found throughout this chapter, we examine similarities between organic and inorganic compounds. From this perspective, you'll see that the behavior of carbon is remarkable, but not unique, in the chemistry of the elements.

Although no element approaches carbon in the variety and complexity of its hydrides, catenation occurs frequently in the periodic table, and many ring, chain, and cage structures are known. Some of the most fascinating belong to the boron hydrides, or boranes (Section 14.5). Although their shapes rival even those of the hydrocarbons, the weakness of their unusual bridge bonds renders most of them thermally and chemically unstable.

An obvious structural similarity exists between alkanes and the silicon hydrides, or silanes (Section 14.6) Silanes even have an analogous general formula $\left(\mathrm{Si}_{n} \mathrm{H}_{2 n+2}\right)$. Branched silanes ate aigowf, but no Eyeheof histurfed (containing an $\mathrm{Si}=\mathrm{Si}$ bond) compounds had been prepared until very recently. Unlike alkanes, silanes are unstable thermally and ignite spontaneously in air.

Sulfur's ability to catenate is second only to carbon's, and many chains and rings occur among its allotropes (Section 14.8). A large series of sulfur hydrides, or polysulfanes, is known. However, these molecules are unbranched chains with H atoms at the ends only $\left(\mathrm{H}-\mathrm{S}_{n}-\mathrm{H}\right)$. Like the silanes, the polysulfanes are oxidized easily and decompose readily to sulfur's only stable hydride, $\mathrm{H}_{2} \mathrm{~S}$, and its most stable allotrope, cyclo- $\mathrm{S}_{8}$.

## Section Summary

Hydrocarbons contain only C and H atoms, so their physical properties depend on the strength of their dispersion forces. - Names of organic compounds have a root for the longest chain, a prefix for any attached group, and a suffix for the type of compound. - Alkanes $\left(\mathrm{C}_{n} \mathrm{H}_{2 n+2}\right)$ have only single bonds. Cycloalkanes $\left(\mathrm{C}_{n} \mathrm{H}_{2 n}\right)$ have ring structures that are typically nonplanar. Alkenes $\left(\mathrm{C}_{n} \mathrm{H}_{2 n}\right)$ have at least one $\mathrm{C}=\mathrm{C}$ bond. Alkynes $\left(\mathrm{C}_{n} \mathrm{H}_{2 n-2}\right)$ have at least one $\mathrm{C} \equiv \mathrm{C}$ bond. Aromatic hydrocarbons have at least one planar ring with delocalized $\pi$ electrons.

Isomers are compounds with the same molecular formula but different properties. - Structural isomers have different atom arrangements. - Stereoisomers (optical and geometric) have the same arrangement of atoms, but their atoms are oriented differently in space. Optical isomers cannot be superimposed on each other because they are asymmetric, with four different groups bonded to the C that is the chiral center. They have identical physical and chemical properties except in their rotation of plane-polarized light and their reaction with chiral reactants. Geometric (cis-trans) isomers have groups oriented differently around a $\mathrm{C}=\mathrm{C}$ bond, which restricts rotation. - Light converts a cis isomer of retinal to the all-trans form, which initiates the visual response. - ${ }^{1} \mathrm{H}$-NMR spectroscopy indicates the relative numbers of H atoms in the various environments within an organic molecule.

Aromatic Carcinogens Polycyclic aromatic compounds have "fused" ring systems, in which two or more rings share one or more sides. The simplest is naphthalene, a feedstock for dyes. Many of these compounds (and benzene itself) have been shown to have carcinogenic (cancer-causing) activity. One of the most potent, benzo[ $a$ ]pyrene, is found in soot, cigarette smoke, car exhaust, and even the smoke from barbecue grills!

## Nuclear Magnetic Resonance (NMR) Spectroscopy

Chemists rely on a battery of instrumental methods to determine the complex structures of organic molecules. We discussed the methods of mass spectrometry in Chapter 2 and infrared (IR) spectroscopy in Chapter 9. One of the most useful tools for analyzing organic and biochemical structures is nuclear magnetic resonance (NMR) spectroscopy, which measures environments of certain nuclei in a molecule to elucidate its structure.

In Chapter 8, we saw that an electron can spin in either of two directions, each of which creates a tiny magnetic field. Several types of nuclei behave in a similar way. The most important of these are ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C},{ }^{19} \mathrm{~F}$, and ${ }^{31} \mathrm{P}$. In this discussion we focus primarily on the proton, ${ }^{1} \mathrm{H}$, the nucleus of the most common isotope of hydrogen, and therefore refer to ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectroscopy. Generally, the magnetic fields of all the protons in a sample of compound are oriented randomly. When placed in a strong external magnetic field $\left(\boldsymbol{B}_{0}\right)$, however, the proton fields become aligned with it (parallel) or against it (antiparallel). The parallel orientation is slightly lower in energy, with the energy difference $(\Delta E)$ between the two energy states (spin states) lying in the radiofrequency (rf) region of the spectrum.

The protons in the sample oscillate rapidly between the two spin states, and in a process known as resonance, the rf value is varied until it matches the frequency of this oscillation. At this point, the protons are "in resonance" with the rf radiation and they absorb and re-emit the energy, which is detected by the rf receiver of the ${ }^{1} \mathrm{H}$-NMR spectrometer (Figure B15.2). If all the protons in a sample required the same $\Delta E$ for resonance a a ${ }^{1} \mathrm{H}-\mathrm{NMR}$ speg trum would have only one peak and be useless. However, the $\Delta E$ between the two states depends on the actual magnetic field felt by each proton, which is affected by the tiny magnetic fields of the electrons of atoms adjacent to that proton. Thus, the $\Delta E$ of each proton depends on the electrons in the adjacent atoms - C atoms, electronegative atoms, multiple bonds, and aromatic rings - in

Figure B15.2 The basis of proton spin resonance. The randomly oriented magnetic fields of protons in a sample become aligned in a strong external field $\left(\boldsymbol{B}_{0}\right)$, with slightly more protons in the lower spin state. In a process called resonance, the spin flips when the proton absorbs a photon with energy equal to $\Delta E$ (radio-frequency region).
other words, on the specific molecular environment. Therefore, the ${ }^{1} \mathrm{H}$-NMR spectrum is unique to that compound.

The ${ }^{1} \mathrm{H}$-NMR spectrum of a compound is a series of peaks that represents the resonance of each proton as a function of the changing magnetic field. The chemical shift of the protons in a given environment is where a peak appears; it represents the ratio of the frequency at which resonance occurs for that proton to the magnitude of the external magnetic field. The chemical shifts are shown relative to that of an added standard, tetramethylsilane [ $\left(\mathrm{CH}_{3}\right)_{4} \mathrm{Si}$, TMS], which has 12 protons bonded to four C atoms that are bonded to one Si atom. Because the shape of TMS is tetrahedral around Si , all 12 protons are in identical environments and $s 0$ produce one peak. Figure B15.3 shows the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of acetone. The six protons of acetone also have identical environments - bonded to two C atoms that are each bonded to the C atom in a $\mathrm{C}=\mathrm{O}$ bond-so they, too, produce one peak, but at a different position from that for TMS. (The axes need not concern us.) The spectrum of dimethoxymethane in Figure B15.4 shows two peaks in addition to the TMS peak. The taller one is due

### 15.3 SOME IMPORTANT CLASSES OF ORGANIC REACTIONS

In Chapter 4, we classified chemical reactions based on the chemical process involved (precipitation, acid-base, or redox) and then briefly included a classification based on the number of reactants and products (combination, decomposition, or displacement). We take a similar approach here with organic reactions.

From here on, we use the notation of an uppercase R with a single bond, R -, to signify a general organic group attached to one of the atoms shown; you can usually picture R - as an alkyl group, a saturated hydrocarbon chain with one bond available to link to another atom. Thus, $\mathrm{R}-\mathrm{CH}_{2}-\mathrm{Br}$ has an alkyl group attached to a $\mathrm{CH}_{2}$ group bearing a Br atom; $\mathrm{R}-\mathrm{CH}=\mathrm{CH}_{2}$ is an alkene with an alkyl group attached to one of the carbons in the double bond; and so forth. (Often, when more than one R group is present, we write $\mathrm{R}, \mathrm{R}^{\prime}, \mathrm{R}^{\prime \prime}$, and so forth, to indicate that these groups may be different.)

## Types of Organic Reactions

Most organic reactions are examples of three broad types that can be identified

Figure B15.3 The ${ }^{1} \mathrm{H}$-NMR spectrum of acetone. The six $\mathrm{CH}_{3}$ protons are in identical environments, so they produce one peak; it has a different chemical shift from that for the 12 protons of the TMS standard.

Figure B15.4 The ${ }^{1} \mathrm{H}$-NMR spectrum of dimethoxymethane. The two peaks show chemical shifts of protons in two different environments. The area under each peak is proportional to the number of protons.
to the six $\mathrm{CH}_{3}$ protons, and the shorter is due to the two $\mathrm{CH}_{2}$ protons. The area under each peak (given here in units of chart-paper spaces) is proportional to the number of protons in a given environment. Note that the area ratio is $20.3 / 6.8 \approx 3 / 1$, the same as the ratio of six $\mathrm{CH}_{3}$ protons to two $\mathrm{CH}_{2}$ protons. Thus, by analyzing the chemical shifts and peak areas, the chemist learns the type and number of hydrogens in the compound.

Newer NMR methods measure the resonance of protons and other nuclei and have many applications in biochemistry and medicine. In fact, Kurt Wüthrich shared the 2002 Nobel Prize in chemistry for developing NMR methods to study biopolymer structures in solution. ${ }^{13} \mathrm{C}$-NMR is used to monitor changes in protein and nucleic acid shape and function, and ${ }^{31} \mathrm{P}-\mathrm{NMR}$ can determine the health of various organs. For example, the extent of damage from a heart attack can be learned by using ${ }^{31} \mathrm{P}-\mathrm{NMR}$ to measure the concentrations of specific phosphate-containing molecules involved in energy utilization by cardiac muscle tissue.

Computer-aided magnetic resonance imaging (MRI) has allowed visualization of damage to organs and greatly assists physicians in medical diagnosis. For example, an MRI scan of the head (Figure B15.5) can show various levels of metabolic activity in different regions of the brain. The 2003 Nobel Prize in physiology or medicine was awarded to Paul C. Lauterbur and Peter Mansfield for their discoveries applying magnetic resonance to imaging of organs and other body parts.

Figure B15.5 Magnetic resonance imaging (MRI) of a brain tumor

1. An addition reaction occurs when an unsaturated reactant becomes a saturated product:

Note the C atoms are bonded to more atoms in the product than in the reactant.
The $\mathrm{C}=\mathrm{C}$ and $\mathrm{C} \equiv \mathrm{C}$ bonds and the $\mathrm{C}=\mathrm{O}$ bond commonly undergo addition reactions. In each case, the $\pi$ bond breaks, leaving the $\sigma$ bond intact. In the product, the two C atoms (or C and O ) form two additional $\sigma$ bonds. Let's examine the standard heat of reaction $\left(\Delta H_{\mathrm{rxn}}^{\circ}\right)$ for a typical addition reaction to see why these reactions occur. Consider the reaction between ethene (common name, ethylene) and HCl :

$$
\begin{aligned}
& \mathrm{CH}_{2}=\mathrm{CH}_{2}+\mathrm{H}-\mathrm{Cl} \longrightarrow \mathrm{H}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{Cl} \\
& \text { Reactants (bonds broken) Product (bonds formed) } \\
& 1 \mathrm{C}=\mathrm{C}=614 \mathrm{~kJ} \quad 1 \mathrm{C}-\mathrm{C}=-347 \mathrm{~kJ} \\
& 4 \mathrm{C}-\mathrm{H}=1652 \mathrm{~kJ} \quad 5 \mathrm{C}-\mathrm{H}=-2065 \mathrm{~kJ} \\
& \frac{1 \mathrm{H}-\mathrm{Cl}=427 \mathrm{~kJ}}{\text { Total }=2693 \mathrm{~kJ}} \quad \frac{1 \mathrm{C}-\mathrm{Cl}=-339 \mathrm{~kJ}}{\text { Total }=-2751 \mathrm{~kJ}} \\
& \Delta H_{\mathrm{rxn}}^{\circ}=\Sigma \Delta H_{\mathrm{b} \text { onds broken }}^{\circ}+\Sigma \Delta H_{\mathrm{b} \text { onds formed }}^{\circ}=2693 \mathrm{~kJ}+(-2751 \mathrm{~kJ})=-58 \mathrm{~kJ}
\end{aligned}
$$

Figure 15.13 A color test for $\mathrm{C}=\mathrm{C}$ bonds. $\mathbf{A}, \mathrm{Br}_{2}$ (in pipet) reacts with a compound that has a $\mathrm{C}=\mathrm{C}$ bond (in beaker), and its orange-brown color disappears:

$B$, The compound in this beaker has no $\mathrm{C}=\mathrm{C}$ bond, so the $\mathrm{Br}_{2}$ does not react, and the orange-brown color remains.

The reaction is exothermic. By looking at the net change in bonds, we see that the driving force for many additions is the formation of two $\sigma$ bonds (in this case, $\mathrm{C}-\mathrm{H}$ and $\mathrm{C}-\mathrm{Cl}$ ) from one $\sigma$ bond (in this case, $\mathrm{H}-\mathrm{Cl}$ ) and one relatively weak $\pi$ bond. An addition reaction is the basis of a color test for the presence of $\mathrm{C}=\mathrm{C}$ bonds (Figure 15.13).
2. Elimination reactions are the opposite of addition reactions. They occur when a saturated reactant becomes an unsaturated product:

Note that the C atoms are bonded to fewer atoms in the product than in the reactant. A pair of halogen atoms, an H atom and a halogen atom, or an H atom and an -OH group are typically eliminated, but C atoms are not. Thus, the driving force for many elimination reactions is the formation of a small, stable molecule, such as $\mathrm{HCl}(g)$ or $\mathrm{H}_{2} \mathrm{O}$, which increases the entropy of the system (Section 13.3):

3. A substitution reaction occurs when an atom (or group) from an added reagent substitutes for one in the organic reactant:

Note that the C atom is bonded to the same number of atoms in the product as in the reactant. The C atom may be saturated or unsaturated, and X and Y can be many different atoms, but generally not C . The main flavor ingredient in banana oil, for instance, forms through a substitution reaction; note that the O substitutes for the Cl:

## SAMPLE PROBLEM 15.3 Recognizing the Type of Organic Reaction

PROBLEM State whether each reaction is an addition, elimination, or substitution:
(a) $\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{Br} \longrightarrow \mathrm{CH}_{3}-\mathrm{CH}=\mathrm{CH}_{2}+\mathrm{HBr}$
(b)

(c) $\mathrm{CH}_{3} \mathrm{C}-\mathrm{Br}+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH} \longrightarrow \mathrm{CH}_{3} \mathrm{C}-\mathrm{OCH}_{2} \mathrm{CH}_{3}+\mathrm{HBr}$

PLAN We determine the type of reaction by looking for any change in the number of atoms bonded to C :

- More atoms bonded to C is an addition.
- Fewer atoms bonded to C is an elimination.
- Same number of atoms bonded to C is a substitution.

SOLUTION
(a) Elimination: two bonds in the reactant, $\mathrm{C}-\mathrm{H}$ and $\mathrm{C}-\mathrm{Br}$, are absent in the product, so fewer atoms are bonded to C .
(b) Addition: two more $\mathrm{C}-\mathrm{H}$ bonds have formed in the product, so more atoms are bonded to C.
(c) Substitution: the reactant $\mathrm{C}-\mathrm{Br}$ bond becomes a $\mathrm{C}-\mathrm{O}$ bond in the product, so the same number of atoms are bonded to C .

FOLLOW-UP PROBLEM 15.3 Write a balanced equation for each of the following:
(a) An addition reaction between 2-butene and $\mathrm{Cl}_{2}$
(b) A substitution reaction between $\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{Br}$ and $\mathrm{OH}^{-}$
(c) The elimination of $\mathrm{H}_{2} \mathrm{O}$ from $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}-\mathrm{OH}$

## The Redox Process in Organic Reactions

An important process in many organic reactions is oxidation-reduction. But chemists do not usually monitor the change in oxidation numbers of the various C atoms in a reaction. Rather, they note the movement of electron density around a C atom by counting the number of bonds to more electronegative atoms (usually O ) or to less electronegative atoms (usually H ). A more electronegative atom takes some electron density from the C, whereas a less electronegative atom gives some electron density to the C. Moreover, even though a redox reaction always involves both an oxidation and a reduction, organic chemists typically focus on the organic reactant only. Therefore,

- When a C atom in the organic reactant forms more bonds to O or fewer bonds to H , the reactant is oxidized and the reaction is called an oxidation.
- When a C atom in the organic reactant forms fewer bonds to O or more bonds to H , the reactant is reduced and the reaction is called a reduction.
The most dramatic redox reactions are combustion reactions. All organic compounds contain C and H atoms and burn in excess $\mathrm{O}_{2}$ to form $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$. For ethane, the reaction is

$$
2 \mathrm{CH}_{3}-\mathrm{CH}_{3}+7 \mathrm{O}_{2} \longrightarrow 4 \mathrm{CO}_{2}+6 \mathrm{H}_{2} \mathrm{O}
$$

Obviously, when ethane is converted to $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$, each of its C atoms has
 tion is referred to as an oxidation, even though $\mathrm{O}_{2}$ is reduced as well.

Most oxidations do not involve such a total breaking apart of the molecule, however. When 2-propanol reacts with potassium dichromate in acidic solution (a common oxidizing agent in organic reactions), the organic compound that forms is 2-propanone:

Note that $\mathrm{C}-2$ has one fewer bond to H and one more bond to O in 2-propanone than it does in 2-propanol. Thus, 2-propanol is oxidized, so this is an oxidation. Don't forget, however, that the dichromate ion is reduced at the same time:

$$
\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}+14 \mathrm{H}^{+}+6 \mathrm{e}^{-} \longrightarrow 2 \mathrm{Cr}^{3+}+7 \mathrm{H}_{2} \mathrm{O}
$$

The addition of $\mathrm{H}_{2}$ to an alkene is referred to as a reduction:

$$
\mathrm{CH}_{2}=\mathrm{CH}_{2}+\mathrm{H}_{2} \xrightarrow{\mathrm{Pd}} \mathrm{CH}_{3}-\mathrm{CH}_{3}
$$

Note that each C has more bonds to H in ethane than it has in ethene, so the ethene is reduced. (The $\mathrm{H}_{2}$ is oxidized in the process, and the palladium shown over the arrow acts as a catalyst to speed up the reaction.)

## Section Summary

In an addition reaction, a $\pi$ bond breaks and the two C atoms bond to more atoms.

- In an elimination, a $\pi$ bond forms and the two $C$ atoms bond to fewer atoms. - In a substitution, one atom replaces another, but the total number of atoms bonded to C does not change. - In an organic redox process, the organic reactant is oxidized if a C atom in the compound forms more bonds to O atoms (or fewer bonds to H atoms), and it is reduced if a C atom forms more bonds to H (or fewer bonds to O ).

Methanol (methyl alcohol) Byproduct in coal gasification; de-icing agent; gasoline substitute; precursor of organic compounds

1,2-Ethanediol (ethylene glycol) Main component of auto antifreeze

Serine
Amino acid found in most proteins

## Cholesterol

Major sterol in animals; essential for cell membranes; precursor of steroid hormones

Figure 15.14 Some molecules with the alcohol functional group.

### 15.4 PROPERTIES AND REACTIVITIES OF COMMON FUNCTIONAL GROUPS

The central organizing principle of organic reaction chemistry is the functional group. To predict how an organic compound might react, we narrow our focus there because the distribution of electron density in a functional group affects the reactivity. The electron density can be high, as in the $\mathrm{C}=\mathrm{C}$ and $\mathrm{C} \equiv \mathrm{C}$ bonds, or it can be low at one end of a bond and high at the other, as in the $\mathrm{C}-\mathrm{Cl}$ and $\mathrm{C}-\mathrm{O}$ bonds. Such bond sites enhance a dipole in the other reactant. As a result, the reactants attract each other and begin a sequence of bond-forming and bondbreaking steps that lead to product. Thus, the intermolecular forces that affect physical properties and solubility also affect reactivity. Table 15.5 lists some of the important functional groups in organic compounds.

When we classify functional groups by bond order (single, double, and so forth), they tend to follow certain patterns of reactivity:

- Functional groups with only single bonds undergo substitution or elimination.
- Functional groups with double or triple bonds undergo addition.
- Functional groups with both single and double bonds undergo substitution.

## Functional Groups with Only Single Bonds

The most common functional groups with only single bonds are alcohols, haloalkanes, and amines.
Alcohols The alcohol functional group consists of carbon bonded to an -OH group, $-\mathrm{C}-\ddot{\mathrm{O}}-\mathrm{H}$, and the general formula of an alcohol is $\mathrm{R}-\mathrm{OH}$. Alcohols
 the suffix -ol. Thus, the two-carbon alcohol is ethanol (ethan- + -ol). The common name is the hydrocarbon root $-+-y l$, followed by "alcohol"; thus, the common name of ethanol is ethyl alcohol. (This substance, obtained from fermented grain, has been consumed by people as an intoxicant in beverages since ancient times; today, it is recognized as the most abused drug in the world.) Alcohols are important laboratory reagents, and the functional group occurs in many biomolecules, including carbohydrates, sterols, and some amino acids. Figure 15.14 shows the names, structures, and uses of some important compounds that contain the alcohol group.

You can think of an alcohol as a water molecule with an R group in place of one of the H atoms. In fact, alcohols react with very active metals, such as the alkali metals [Group 1A(1)], in a manner similar to water:

$$
\begin{aligned}
2 \mathrm{Na}+2 \mathrm{HOH} & \longrightarrow 2 \mathrm{NaOH}+\mathrm{H}_{2} \\
2 \mathrm{Na}+2 \mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{OH} & \longrightarrow 2 \mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{ONa}+\mathrm{H}_{2}
\end{aligned}
$$

Water forms a solution of the strongly basic hydroxide ion $\left(\mathrm{HO}^{-}\right)$, and an alcohol forms a solution of the strongly basic alkoxide ion $\left(\mathrm{RO}^{-}\right)$: ethanol forms the ethoxide ion $\left(\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{O}^{-}\right)$. The physical properties of the smaller alcohols are also similar to those of water. They have high melting and boiling points as a result of hydrogen bonding, and they dissolve polar molecules and some salts. (Substitution of R groups for both H atoms of water gives ethers, $\mathrm{R}-\mathrm{O}-\mathrm{R}$.)

Alcohols undergo elimination and substitution reactions. Dehydration, the elimination of H and OH , requires acid and forms alkenes:

Table 15.5 Important Functional Groups in Organic Compounds

| Functional Group | Compound Type | Prefix or Suffix of Name | Example |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | Lewis Ball-and-Stick <br> Structure Model | Systematic Name (Common Name) |
| $\mathrm{C}=\mathrm{C}^{\prime}$ | alkene | -ene |  | ethene (ethylene) |
| -C $\equiv \mathrm{C}-$ | alkyne | -yne | $\mathrm{H}-\mathrm{C} \equiv \mathrm{C}-\mathrm{H}$ | ethyne (acetylene) |
|  | alcohol | -ol |  | methanol (methyl alcohol) |
|  | haloalkane | halo- |   | chloromethane (methyl chloride) |
|  | amine | -amine |  | ethanamine (ethylamine) |
|  | aldehyde | $\underset{-a t}{A_{-1}}$ |  | ethanal (acetaldehyde) |
|  | ketone | -one |  | 2-propanone (acetone) |
|  | carboxylic acid | -oic acid |  | ethanoic acid (acetic acid) |
|  | ester | -oate |  | methyl ethanoate (methyl acetate) |
|  | amide | -amide |   | ethanamide (acetamide) |
| - $\mathrm{C} \equiv \mathrm{N}$ : | nitrile | -nitrile |  | ethanenitrile (acetonitrile, methyl cyanide) |

Pollutants in the Food Chain Until recently, halogenated aromatic hydrocarbons, such as the polychlorinated biphenyls (PCBs; one of 209 different compounds is shown above), were used as insulating fluids in electrical transformers and then discharged in wastewater. Because of their low solubility and high stability, they accumulate for decades in river and lake sediment and are eaten by microbes and invertebrates. Fish eat the invertebrates, and birds and mammals, including humans, eat the fish. PCBs become increasingly concentrated in body fat at each stage. As a result of their health risks, PCBs in natural waters present an enormous cleanup problem.

Elimination of two H atoms requires inorganic oxidizing agents, such as $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ in aqueous $\mathrm{H}_{2} \mathrm{SO}_{4}$. As we saw in Section 15.3, the reaction is an oxidation and produces the $\mathrm{C}=\mathrm{O}$ group (shown with condensed and carbon-skeleton formulas):

For alcohols with an OH group at the end of the chain $\left(\mathrm{R}-\mathrm{CH}_{2}-\mathrm{OH}\right)$, another oxidation occurs. Wine turns sour, for example, when the ethanol in contact with air is oxidized to acetic acid:

Substitution yields products with other single-bonded functional groups. With hydrohalic acids, many alcohols give haloalkanes:

$$
\mathrm{R}_{2} \mathrm{CH}-\mathrm{OH}+\mathrm{HBr} \longrightarrow \mathrm{R}_{2} \mathrm{CH}-\mathrm{Br}+\mathrm{HOH}
$$

As you'll see below, the $C$ atom undergoing the change in a substitution is bonded to a more electronegative element, which makes it partially positive and, thus, a target for a negatively charged or electron-rich group of an incoming reactant.

Haloalkanes A halogen atom ( X ) bonded to C gives the haloalkane functional group, $-\stackrel{\mid}{\mathrm{C}}-\ddot{\mathrm{X}}:$ : and compounds with the general formula $\mathrm{R}-\mathrm{X}$. Haloalkanes (common-hame, alkyt halides) are named by adding the halogen as a prefix to the hydrocarbon name and numbering the C atom to which the halogen is attached, as in bromomethane, 2-chloropropane, or 1,3-diiodohexane.

Just as many alcohols undergo substitution to alkyl halides when treated with halide ions in acid, many halides undergo substitution to alcohols in base. For example, $\mathrm{OH}^{-}$attacks the positive C end of the $\mathrm{C}-\mathrm{X}$ bond and displaces $\mathrm{X}^{-}$:

Substitution by groups such as $-\mathrm{CN},-\mathrm{SH},-\mathrm{OR}$, and $-\mathrm{NH}_{2}$ allows chemists to convert alkyl halides to a host of other compounds.

Just as addition of HX to an alkene produces haloalkanes, elimination of HX from a haloalkane by reaction with a strong base, such as potassium ethoxide, produces an alkene:

Haloalkanes have many important uses, but many are carcinogenic in mammals, have severe neurological effects in humans, and, to make matters worse, are very stable and accumulate in the environment.
Amines The amine functional group is $-\underset{\mid}{\mid} \ddot{\mathrm{N}}-$. Chemists classify amines as derivatives of ammonia, with R groups in place of one or more H atoms. Primary $\left(1^{\circ}\right)$ amines are $\mathrm{RNH}_{2}$, secondary $\left(2^{\circ}\right)$ amines are $\mathrm{R}_{2} \mathrm{NH}$, and tertiary $\left(3^{\circ}\right)$ amines are $\mathrm{R}_{3} \mathrm{~N}$. Like ammonia, amines have trigonal pyramidal shapes and a lone pair

Figure 15.15 General structures of amines. Amines have a trigonal pyramidal shape and are classified by the number of R groups bonded to N . The lone pair on the nitrogen atom is the key to amine reactivity.
of electrons on a partially negative N atom (Figure 15.15). Systematic names drop the final $-e$ of the alkane and add the suffix -amine, as in ethanamine. However, there is still wide usage of common names, in which the suffix -amine follows the name of the alkyl group; thus, methylamine has one methyl group attached to N, diethylamine has two ethyl groups attached, and so forth. Figure 15.16 shows that the amine functional group occurs in many biomolecules.

Primary and secondary amines can form H bonds, so they have higher melting and boiling points than hydrocarbons and alkyl halides of similar molar mass. For example, dimethylamine $(\mathcal{M}=45.09 \mathrm{~g} / \mathrm{mol})$ boils $45^{\circ} \mathrm{C}$ higher than ethyl fluoride ( $\mathcal{M}=48.06 \mathrm{~g} / \mathrm{mol}$ ). Trimethylamine has a greater molar mass than dimethylamine, but it melts more than $20^{\circ} \mathrm{C}$ lower because trimethylamine molecules are not H bonded.

Amines of low molar mass are fishy smelling, water soluble, and weakly basic. The reaction with water proceeds only slightly to the right to reach equilibrium:

Amines undergo substitution reactions in which the lone pair on N attacks the partially positive C in alkyl halides to displace $\mathrm{X}^{-}$and form a larger amine:

(Two molecules of ethylamine are needed: while one attacks the chloroethane, the other binds the released $\mathrm{H}^{+}$to prevent it from remaining on the diethylamine.)

Lysine (primary amine)
Amino acid found in most proteins

Adenine (primary amine) Component of nucleic acids

Epinephrine (adrenaline; secondary amine)
Neurotransmitter in brain; hormone released during stress

Cocaine (tertiary amine) Brain stimulant; widely abused drug

Figure 15.16 Some biomolecules with the amine functional group.

## Variations on a Theme: Inorganic Compounds with Single Bonds to $\mathbf{O}, \mathbf{X}$, and N

The - OH group occurs frequently in inorganic compounds. All oxoacids contain at least one -OH , usually bonded to a relatively electronegative nonmetal atom, which in most cases is bonded to other O atoms. Oxoacids are acidic in water because these additional O atoms pull electron density from the central nonmetal, which pulls electron density from the $\mathrm{O}-\mathrm{H}$ bond, releasing an $\mathrm{H}^{+}$ion and stabilizing the oxoanion through resonance. Alcohols are not acidic in water because they lack the additional O atoms and the electronegative nonmetal.

Halides of nearly every nonmetal are known, and many undergo substitution reactions in base. As in the case of an alkyl halide, the process involves an attack on the partially positive central atom by $\mathrm{OH}^{-}$:

Thus, alkyl halides undergo the same general reaction as other nonmetal halides, such as $\mathrm{BCl}_{3}, \mathrm{SiF}_{4}$, and $\mathrm{PCl}_{5}$.

The bonds between nitrogen and larger nonmetals, such as $\mathrm{Si}, \mathrm{P}$, and S , have significant double-bond character, which affects structure and reactivity. For example, trisilylamine, the Si analog of trimethylamine (see Figure 14.16, p. 590), is planar, rather than trigonal pyramidal, partially as a result of $p, d-\pi$ bonding. The lone pair on N is delocalized in this $\pi$ bond, so trisilylamine is not basic.

## SAMPLE PROBLEM 15.4 Predicting the Reactions of Alcohols, Alkyl Halides, and Amines

PROBLEM Determine the reaction type and predict the product(s) for each reaction:
(a) $\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{I}+\mathrm{NaOH} \longrightarrow$

PLAN We first determine the functional group(s) of the reactant(s) and then examine any inorganic reagent(s) to decide on the reaction type, keeping in mind that, in general, these functional groups undergo substitution or elimination. In (a), the reactant is an alkyl halide, so the $\mathrm{OH}^{-}$of the inorganic reagent substitutes for the I. In (b), the reactants are an amine and an alkyl halide, so the N of the amine substitutes for the Br . In (c), the reactant is an alcohol, the inorganic reagents form a strong oxidizing agent, and the alcohol undergoes elimination to a carbonyl compound.
SOLUTION (a) Substitution: The products are $\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{OH}+\mathrm{NaI}$
(b) Substitution: The products are $\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\underset{\mid}{\mathrm{NH}}+\mathrm{CH}_{2}-\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\stackrel{+}{\mathrm{N}} \mathrm{H}_{3} \mathrm{Br}^{-}$
(c) Elimination: (oxidation): The product is $\mathrm{CH}_{3}-\underset{\|}{\mathrm{C}}-\mathrm{CH}_{3}$

CHECK The only changes should be at the functional group.
FOLLOW-UP PROBLEM 15.4 Fill in the blank in each reaction. (Hint: Examine any inorganic compounds and the organic product to determine the organic reactant.)
(a)

(b)

## Functional Groups with Double Bonds

The most important functional groups with double bonds are the $\mathrm{C}=\mathrm{C}$ of alkenes and the $\mathrm{C}=\mathrm{O}$ of aldehydes and ketones. Both appear in many organic and biological molecules. Their most common reaction type is addition.

## Comparing the Reactivity of Alkenes and Aromatic Compounds The $\mathrm{C}=\mathrm{C}$

bond is the essential portion of the alkene functional group, ${ }^{\prime} \mathrm{C}=\mathrm{C}_{\searrow}^{\prime}$. Although they can be further unsaturated to alkynes, alkenes typically undergo addition. The electron-rich double bond is readily attracted to the partially positive H atoms of hydronium ions and hydrohalic acids, yielding alcohols and alkyl halides, respectively:

The localized unsaturation of alkenes is very different from the delocalized unsaturation of benzene. Despite the way we depiet its fesonance forms benzene does not have double bonds. Thus, fof example, benzene does nôt decolorize $\mathrm{Br}_{2}$.

In general, aromatic rings are much less reactive than alkenes because they have delocalized $\pi$ electrons. For example, let's compare the heats of reaction for the addition of $\mathrm{H}_{2}$. Hydrogenation of cyclohexene, with one $\mathrm{C}=\mathrm{C}$ bond, has a $\Delta H_{\mathrm{rxn}}^{\circ}$ of $-120 \mathrm{~kJ} / \mathrm{mol}$. If we extrapolate to the imaginary molecule "cyclohexatriene," that is, the structure with three $\mathrm{C}=\mathrm{C}$ bonds, its hypothetical $\Delta H_{\mathrm{rxn}}^{\circ}$ for hydrogenation is three times as much, or $-360 \mathrm{~kJ} / \mathrm{mol}$. Hydrogenation of benzene has a $\Delta H_{\mathrm{rxn}}^{\circ}$ of $-208 \mathrm{~kJ} / \mathrm{mol}$. Thus, the $\Delta H_{\mathrm{rxn}}^{\circ}$ for hydrogenation of benzene is $152 \mathrm{~kJ} / \mathrm{mol}$ less than that for "cyclohexatriene," an energy difference attributed to the aromatic stabilization of benzene (Figure 15.17).

This extra energy needed to break up the delocalized $\pi$ system means addition reactions with benzene occur rarely. But, benzene does undergo many substitution reactions in which the delocalization is retained when an H atom attached to a ring C is replaced by another group:

Aldehydes and Ketones The $\mathrm{C}=\mathrm{O}$ bond, or carbonyl group, is one of the most chemically versatile. In the aldehyde functional group, the carbonyl C is bonded to H (and often to another C ), so it occurs at the end of a chain, $\mathrm{R}-\mathrm{C}=\mathrm{O}$. Aldehyde names drop the final -e from the alkane name and add -al; thus, the three-C aldehyde is propanal. In the ketone functional group, the carbonyl C is bonded to two other C atoms,

Figure 15.17 The stability of benzene.
Because of the resonance stabilization caused by the aromatic $\pi$-electron system in benzene, the molecule releases $152 \mathrm{~kJ} / \mathrm{mol}$ less energy when it is hydrogenated than would "cyclohexatriene," the analogous molecule with three separate double bonds.

Methanal (formaldehyde)
Used to make resins in plywood, dishware, countertops; biological preservative

Ethanal (acetaldehyde) Narcotic product of ethano metabolism; used to make perfumes, flavors, plastics, other chemicals

Benzaldehyde
Artificial almond flavoring

2-Propanone (acetone) Solvent for fat, rubber, plastic, varnish, lacquer; chemical feedstock

2-Butanone (methyl ethyl ketone) Important solvent

Figure 15.18 Some common aldehydes and ketones.

Figure 15.19 The carbonyl group.
A, The $\sigma$ and $\pi$ bonds that make up the $\mathrm{C}=\mathrm{O}$ bond of the carbonyl group. $\mathbf{B}$, The charged resonance form shows that the $\mathrm{C}=\mathrm{O}$ bond is polar $(\Delta \mathrm{EN}=1.0)$.

Ketones, $R-\stackrel{\mathrm{O}}{\mathrm{C}}-\mathrm{R}^{\prime}$, are named by numbering the carbonyl C , dropping the final $-e$ from the alkane name, and adding -one. For example, the unbranched, five-C ketone with the carbonyl C as C-2 in the chain is named 2-pentanone. Figure 15.18 shows some common carbonyl compounds.

Like the $\mathrm{C}=\mathrm{C}$ bond, the $\mathrm{C}=\mathrm{O}$ bond is electron rich; unlike the $\mathrm{C}=\mathrm{C}$ bond, it is highly polar $(\Delta \mathrm{EN}=1.0)$. Figure 15.19 emphasizes this polarity with an electron density model and a charged resonance form. Aldehydes and ketones are formed by the oxidation of alcohols:

Conversely, as a result of their unsaturation, carbonyl compounds can undergo addition and be reduced to alcohols:

As a result of the bond polarity, addition often occurs with an electron-rich group bonding to the carbonyl C and an electron-poor group bonding to the carbonyl O. Organometallic compounds, which have a metal atom (usually Li or Mg ) attached to an R group through a polar covalent bond (Sections 14.3 and 14.4), take part in this type of reaction. In a two-step sequence, they convert carbonyl compounds to alcohols with different carbon skeletons:

In the following reaction steps, for example, the electron-rich C bonded to Li in ethyllithium, $\mathrm{CH}_{3} \mathrm{CH}_{2}-\mathrm{Li}$, attacks the electron-poor carbonyl C of 2-propanone, adding its ethyl group; at the same time, the Li adds to the carbonyl O . Treating the mixture with water forms the $\mathrm{C}-\mathrm{OH}$ group:

Note that the product skeleton combines the two reactant skeletons. The field of organic synthesis often employs organometallic compounds to create molecules with different skeletons and, thus, synthesize new compounds.

SAMPLE PROBLEM 15.5 Predicting the Steps in a Reaction Sequence
PROBLEM Fill in the blanks in the following reaction sequence:

PLAN For each step, we examine the functional group of the reactant and the reagent above the yield arrow to decide on the most likely product.
SOLUTION The sequence starts with an alkyl halide reacting with $\mathrm{OH}^{-}$. Substitution gives an alcohol. Oxidation of this alcohol with acidic dichromate gives a ketone. Finally, a twostep reaction of a ketone with $\mathrm{CH}_{3}-\mathrm{Li}$ and then water forms an alcohol with a carbon skeleton that has the $\mathrm{CH}_{3}-$ group attached to the carbonyl C :

CHECK In this case, make sure that the first two reactions alter the functional group only and that the final steps change the C skeleton.
FOLLOW-UP PROBLEM 15.5 Choose reactants to obtain the following products:

Variations on a Theme: Inorganic Compounds with Double Bonds Homonuclear (same kind of atom) double bonds are rare for atoms other than C. However, we've seen many double bonds between O and other nonmetals, for example, in the oxides of $\mathrm{S}, \mathrm{N}$, and the halogens. Like carbonyl compounds, these substances undergo addition reactions. For example, the partially negative O of water attacks the partially positive S of $\mathrm{SO}_{3}$ to form sulfuric acid:

## Functional Groups with Both Single and Double Bonds

A family of three functional groups contains C double bonded to O (a carbonyl group) and single bonded to O or N . The parent of the family is the carboxylic
acid group, $-\stackrel{\|}{\mathrm{C}}-\ddot{\mathrm{O}} \mathrm{H}$, also called the carboxyl group and written -COOH . The most important reaction type of this family is substitution from one member to another. Substitution for the - OH by the - OR of an alcohol gives the ester
group, $-\stackrel{\text { :O: }}{\mathrm{C}}-\stackrel{\mathrm{O}}{\mathrm{O}}-\mathrm{R}$;
substitution by the $-\underset{\mathrm{N}}{\mathrm{I}}-$ of an amine gives the amide

Methanoic acid (formic acid)
An irritating component
of ant and bee stings

Butanoic acid (butyric acid)
Odor of rancid butter; suspected component of monkey sex attractant

Benzoic acid
Calorimetric standard; used in preserving food, dyeing fabric, curing tobacco

Octadecanoic acid (stearic acid)
Found in animal fats; used in making candles and soaps

Figure 15.20 Some molecules with the carboxylic acid functional group.
 from the alkane name and adding -oic acid; however, many common names are used. For example, the four- C acid is butanoic acid (the carboxyl C is counted when choosing the root); its common name is butyric acid. Figure 15.20 shows some important carboxylic acids. The carboxyl C already has three bonds, so it forms only one other. In formic acid (methanoic acid), the carboxyl C bonds to an H , but in all other carboxylic acids it bonds to a chain or ring.

Carboxylic acids are weak acids in water:

At equilibrium in acid solutions of typical concentration, more than $99 \%$ of the acid molecules are undissociated at any given moment. In strong base, however, they react completely to form a salt and water:

The anion is the carboxylate ion, named by dropping -oic acid and adding -oate; the sodium salt of butanoic acid, for instance, is sodium butanoate.

Carboxylic acids with long hydrocarbon chains are fatty acids, an essential group of compounds found in all cells. Animal fatty acids have saturated chains, whereas many from vegetable sources are unsaturated, usually with the $\mathrm{C}=\mathrm{C}$ bonds in the cis configuration. The double bond makes them much easier to metabolize. Nearly all fatty acid skeletons have an even number of C atoms-16
 thesizing them. Fatty acid salts are soaps, with the cation usually from Group $1 \mathrm{~A}(1)$ or $2 \mathrm{~A}(2)$ (Section 13.2).

Substitution of carboxylic acids and other members of this family occurs through a two-step sequence: addition plus elimination equals substitution. Addition to the trigonal planar shape of the carbonyl group gives an unstable tetrahedral intermediate, which immediately undergoes elimination to revert to a trigonal planar product (in this case, X is OH ):

Strong heating of carboxylic acids forms an acid anhydride through a type of substitution called a dehydration-condensation reaction (Section 14.7), in which two molecules condense into one with loss of water:

Esters An alcohol and a carboxylic acid form an ester. The first part of an ester name designates the alcohol portion and the second the acid portion (named in the same way as the carboxylate ion). For example, the ester formed between ethanol and ethanoic acid is ethyl ethanoate (common name, ethyl acetate), a solvent for nail polish and model glue.

The ester group occurs commonly in lipids, a large group of fatty biological substances. Most dietary fats are triglycerides, esters composed of three fatty acids linked to the alcohol 1,2,3-trihydroxypropane (common name, glycerol) that

Cetyl palmitate The most common lipid in whale blubber

Lecithin Phospholipid found in all cell membranes
Figure 15.21 Some lipid molecules with the ester functional group.
function as energy stores. Some important lipids are shown in Figure 15.21; lecithin is one of several phospholipids that make up the lipid bilayer in all cell membranes (Section 13.2).

Esters, like acid anhydrides, form through a dehydration-condensation reaction; in this case, it is called an esterification:

In Chapter 16, we will discuss the role of $\mathrm{H}^{+}$in increasing the rate of this multistep reaction.

Note that the esterification reaction is reversible The opposite of dehydrationcondensation is called hydrolysis, in Phith the $\Theta$ atom of when is attacted to the partially positive C atom of the ester, cleaving (lysing) the molecule into two parts. One part receives water's -OH , and the other part receives water's other H. In the process of soap manufacture, or saponification (Latin sapon, "soap"), begun in ancient times, ester bonds in animal or vegetable fats are hydrolyzed with strong base:

Amides The product of a substitution between an amine ( or $\mathrm{NH}_{3}$ ) and an ester is an amide. The partially negative N of the amine is attracted to the partially positive C of the ester, an alcohol ( ROH ) is lost, and an amide forms:

Amides are named by denoting the amine portion with $N$ - and replacing -oic acid from the parent carboxylic acid with -amide. In the amide from the previous

A Pungent, Pleasant Banquet Many organic compounds have strong odors, but none can rival the diverse odors of carboxylic acids and esters. From the pungent, vinegary odors of the one-C and two-C acids to the cheesy stench of slightly larger ones, carboxylic acids possess some awful odors. When butanoic acid reacts with ethanol, however, its rancid-butter smell becomes the peachy pineapple scent of ethyl butanoate, and when pentanoic acid reacts with pentanol, its Limburger cheese odor becomes the fresh apple aroma of pentyl pentanoate. Naturally occurring and synthetic esters are used to add fruity, floral, and herbal odors to foods, cosmetics, household deodorizers, and medicines.

Lysergic acid diethylamide (LSD-25) A potent hallucinogen
reaction, the ethyl group comes from the amine, and the acid portion comes from ethanoic acid (acetic acid). Some amides are shown in Figure 15.22.

Amides are hydrolyzed in hot water (or base) to a carboxylic acid and an amine. Thus, even though amides are not normally formed in the following way, they can be viewed as the result of a reversible dehydration-condensation:

The most important example of the amide group is the peptide bond (discussed in Sections 13.2 and 15.6), which links amino acids in a protein.

The carboxylic acid family also undergoes reduction to form other functional groups. For example, certain inorganic reducing agents convert acids or esters to akohols and conver wides tomamesiceェ

## SAMPLE PROBLEM 15.6 Predicting Reactions of the Carboxylic Acid Family

PROBLEM Predict the product(s) of the following reactions:
(a)

(b)

PLAN We discussed substitution reactions (including addition-elimination and dehydrationcondensation) and hydrolysis. (a) A carboxylic acid and an alcohol react, so the reaction must be a substitution to form an ester and water. (b) An amide reacts with $\mathrm{OH}^{-}$, so it is hydrolyzed to an amine and a sodium carboxylate.
SOLUTION (a) Formation of an ester:

(b) Basic hydrolysis of an amide:

CHECK Note that in part (b), the carboxylate ion forms, rather than the acid, because the aqueous NaOH that is present reacts with the carboxylic acid.

FOLLOW-UP PROBLEM 15.6 Fill in the blanks in the following reactions:
(a)

(b) $\qquad$ $+$ $\longrightarrow \mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{C}-\mathrm{NH}-\mathrm{CH}_{2}-\mathrm{CH}_{3}$ $+\mathrm{C}$ $\mathrm{CH}_{3}-\mathrm{OH}$

Variations on a Theme: Oxoacids, Esters, and Amides of Other Nonmetals
A nonmetal that is both double and single bonded to O occurs in most inorganic oxoacids, such as phosphoric, sulfuric, and chlorous acids. Those with additional O atoms are stronger acids than carboxylic acids.

Diphosphoric and disulfuric acids are acid anhydrides formed by dehydrationcondensation reactions, just as a carboxylic acid anhydride is formed (Figure 15.23). Inorganic oxoacids form esters and amides that are part of many biological molecules. We already saw that certain lipids are phosphate esters (see Figure 15.21). The first compound formed when glucose is digested is a phosphate ester (Figure 15.24 A ); a similar phosphate ester is a major structural feature of nucleic acids, as we'll see shortly. Amides of organic sulfur-containing oxoacids, called sulfonamides, are potent antibiotics; the simplest of these is depicted in Figure 15.24 B . More than 10,000 different sulfonamides have been synthesized.

A Glucose-6-phosphate

B Sulfanilamide

## Functional Groups with Triple Bonds

There are only two important functional groups with triple bonds. Alkynes, with an electron-rich $-\mathrm{C} \equiv \mathrm{C}$ - group, undergo addition (by $\mathrm{H}_{2} \mathrm{O}, \mathrm{H}_{2}, \mathrm{HX}, \mathrm{X}_{2}$, and so forth) to form double-bonded or saturated compounds:

Nitriles ( $\mathrm{R}-\mathrm{C} \equiv \mathrm{N}$ ) contain the nitrile group ( $-\mathrm{C} \equiv \mathrm{N}$ :) and are made by substituting a $\mathrm{CN}^{-}$(cyanide) ion for $\mathrm{X}^{-}$in a reaction with an alkyl halide:

$$
\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{Cl}+\mathrm{NaCN} \longrightarrow \mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{C} \equiv \mathrm{~N}+\mathrm{NaCl}
$$

This reaction is useful because it increases the hydrocarbon chain by one $C$ atom. Nitriles are versatile because once they are formed, they can be reduced to amines or hydrolyzed to carboxylic acids:

Variations on a Theme: Inorganic Compounds with Triple Bonds Triple bonds are as scarce in the inorganic world as in the organic world. Carbon monoxide $\left(: \mathrm{C} \equiv \mathrm{O}:\right.$ ), elemental nitrogen ( $: \mathrm{N} \equiv \mathrm{N}:$ ), and the cyanide ion ( $[: \mathrm{C} \equiv \mathrm{N}:]^{-}$) are the only common examples.

You've seen quite a few functional groups by this time, and it is especially important that you can recognize them in a complex organic molecule. Sample Problem 15.7 provides some practice.

## Section Summary

Organic reactions are initiated when regions of high and low electron density of different reactant molecules attract each other. • Groups containing only single bondsalcohols, amines, and alkyl halides-take part in substitution and elimination reactions. - Groups with double or triple bonds-alkenes, aldehydes, ketones, alkynes, and nitriles-generally take part in addition reactions. - Aromatic compounds typically undergo substitution, rather than addition, because delocalization of the $\pi$ electrons stabilizes the ring. - Groups with both double and single bonds-carboxylic acids, esters, and amides-generally take part in substitution reactions. - Many reactions change one functional group to another, but some, especially reactions with organometallic compounds and with the cyanide ion, change the $C$ skeleton.

### 15.5 THE MONOMER-POLYMER THEME I: SYNTHETIC MACROMOLECULES

In our survey of advanced materials in Chapter 12, you saw that polymers are extremely large molecules that consist of many monomeric repeat units. In that chapter, we focused on the mass, shape, and physical properties of polymers. Now we'll see how polymers are named and discuss the two types of reactions that link monomers covalently into a chain. To name a polymer, just add the prefix poly- to the monomer name, as in polyethylene or polystyrene. When the monomer has a two-word name, parentheses are used, as in poly(vinyl chloride).

Because synthetic polymers consist of petroleum-based monomers, a major shortage of raw materials for their manufacture is expected in the coming decades.

To avoid this and create renewable materials, green chemists are devising polymers based on corn, sugarcane, and even cashew-nut shells. Before such a method is embraced as a "green" technology, however, the total impact of growing, transporting, and manufacturing must be assessed.

The two major types of reaction processes that form synthetic polymers lend their names to the resulting classes of polymer-addition and condensation.

## Addition Polymers

Addition polymers form when monomers undergo an addition reaction with one another. These are also called chain-reaction (or chain-growth) polymers because as each monomer adds to the chain, it forms a new reactive site to continue the process. The monomers of most addition polymers have the $\mathrm{C}^{\searrow}=\mathrm{C}_{\backslash}^{\prime}$ grouping. As you can see from Table 15.6, the essential differences between an acrylic sweater, a plastic grocery bag, and a bowling ball are due to the different chemical groups that are attached to the double-bonded C atoms of the monomer.

## Table 15.6 Some Major Addition Polymers

Step 1 Formation of free radical
$2 \mathrm{Y}-\mathrm{O}$.
Step 2 Addition of monomer

Step 3

Step 4

The free-radical polymerization of ethene (ethylene, $\mathrm{CH}_{2}=\mathrm{CH}_{2}$ ) to polyethylene is a simple example of the addition process. In Figure 15.25, the monomer reacts to form a free radical, a species with an unpaired electron, that seeks an electron from another monomer to form a covalent bond. The process begins when an initiator, usually a peroxide, generates a free radical that attacks the $\pi$ bond of an ethylene unit, forming a $\sigma$ bond with one of the $p$ electrons and leaving the other unpaired. This new free radical then attacks the $\pi$ bond of another ethylene, joining it to the chain end, and the backbone of the polymer grows. As each ethylene adds, it leaves an unpaired electron on the growing end to find an electron "mate" and make the chain one repeat unit longer. This process stops when two free radicals form a covalent bond or when a very stable free radical is formed by addition of an inhibitor molecule. Recent progress in controlling the high reactivity of free-radical species promises an even wider range of polymers. In a similar method, polymerization is initiated by the formation of a cation (or anion) instead of a free radical. The cationic (or anionic) reactive end of the chain attacks the $\pi$ bond of another monomer to form a new cationic (or anionic) end, and the process continues.

The most important polymerization reactions take place under relatively mild conditions through the use of catalysts that incorporate transition metals. In 1963, Karl Ziegler and Giulio Natta received the Nobel Prize in chemistry for developing Ziegler-Natta catalysts, which employ an organoaluminum compound, such as $\mathrm{Al}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{3}$, and the tetrachloride of titanium or vanadium. Today, chemists use organometallic catalysts that are stereoselective to create polymers whose repeat units have groups spatially oriented in particular ways. Through the use of these catalysts, polyethylene chains with molar masses of $10^{4}$ to $10^{5} \mathrm{~g} / \mathrm{mol}$ are made by varying conditions and reagents.

all the $\mathrm{CH}_{3}$ groups of the repeat units oriented either on one side of the chain or on alternating sides. The different orientations lead to different packing efficiencies of the chains and, thus, different degrees of crystallinity, which lead to differences in such physical properties as density, rigidity, and elasticity (Section 12.7).

## Condensation Polymers

The monomers of condensation polymers must have two functional groups; we can designate such a monomer as $\mathrm{A}-\mathbf{R}-\mathrm{B}$ (where $\mathbf{R}$ is the rest of the molecule). Most commonly, the monomers link when an A group on one undergoes a dehydration-condensation reaction with a B group on another:
$\frac{1}{2} n \mathrm{H}-\mathrm{A}-\mathrm{R}-\mathrm{B}-\mathrm{OH}+\frac{1}{2} n \mathrm{H}-\mathrm{A}-\mathrm{R}-\mathrm{B}-\mathrm{OH} \xrightarrow{-(n-1) \mathrm{HOH}}$

$$
\mathrm{H}\left\lceil\mathrm{~A}-\mathrm{R}-\mathrm{B} \dashv_{n} \mathrm{OH}\right.
$$

Many condensation polymers are copolymers, those consisting of two or more different repeat units (Section 12.7). For example, condensation of carboxylic acid and amine monomers forms polyamides (nylons), whereas carboxylic acid and alcohol monomers form polyesters.

One of the most common polyamides is nylon-66 (see the Gallery, p. 74), manufactured by mixing equimolar amounts of a six-C diamine ( 1,6 -diaminohexane)

Figure 15.25 Steps in the free-radical polymerization of ethylene. In this polymerization method, free radicals initiate, propagate, and terminate the formation of an addition polymer. An initiator ( $\mathrm{Y}-\mathrm{O}-\mathrm{O}-\mathrm{Y}$ ) is split to form two molecules of a free radical ( $\mathrm{Y}-\mathrm{O} \cdot)$. The free radical attacks the $\pi$ bond of a monomer and creates another free radical $\left(\mathrm{Y}-\mathrm{O}-\mathrm{CH}_{2}-\mathrm{CH}_{2} \cdot\right)$. The process continues, and the chain grows (propagates) until the system runs out of monomer and two free radicals combine.
and a six-C diacid (1,6-hexanedioic acid). The basic amine reacts with the acid to form a "nylon salt." Heating drives off water and forms the amide bonds:

In the laboratory, this nylon is made without heating by using a more reactive acid component (Figure 15.26). Covalent bonds within the chains give nylons great strength, and H bonds between chains give them great flexibility. About half of all nylons are made to reinforce automobile tires; the others are used for rugs, clothing, fishing line, and so forth.

Dacron, a popular polyester fiber, is woven from polymer strands formed when equimolar amounts of 1,4-benzenedicarboxylic acid and 1,2-ethanediol react. Blending these polyester fibers with various amounts of cotton gives fabrics that are durable, easily dyed, and crease resistant. Extremely thin Mylar films, used for recording tape and food packaging, are also made from this polymer.
Variations on a Theme: Inorganic Polymers You already know that some synthetic polymers have inorganic backbones. In Chapter 14, we discussed the silicones, polymers with the repeat unit $-\left(\mathrm{R}_{2}\right) \mathrm{Si}-\mathrm{O}-$. Depending on the chain crosslinks and the R groups, silicones range from oily liquids to elastic sheets to rigid solids and have applications that include artificial limbs and spacesuits. We also mentioned the polyphosphazenes in Chapter 14, which exist as flexible chains even at low temperatures and have the repeat unit $-\left(\mathrm{R}_{2}\right) \mathrm{P}=\mathrm{N}-$.

## Section Summary

Polymers are extremely large molecules that are made of repeat units called monomers. - Addition polymers are formed from unsaturated monomers that commonly link through free-radical reactions. Möstcondensation polymers are formed by linking two types of monomer through a dehydration-condensation reaction.

- Reaction conditions, catalysts, and monomers can be varied to produce polymers with different properties.

### 15.6 THE MONOMER-POLYMER THEME II: BIOLOGICAL MACROMOLECULES

The monomer-polymer theme was being played out in nature eons before humans employed it to such great advantage. Biological macromolecules are nothing more than condensation polymers created by nature's reaction chemistry and improved through evolution. These remarkable molecules are the greatest proof of the versatility of carbon and its handful of atomic partners.

Natural polymers are the "stuff of life"-polysaccharides, proteins, and nucleic acids. Some have structures that make wood strong, hair curly, fingernails hard, and wool flexible. Others speed up the myriad reactions that occur in every cell or defend the body against infection. Still others possess the genetic information organisms need to forge other biomolecules. Remarkable as these giant molecules are, the functional groups of their monomers and the reactions that link them are identical to those of other, smaller organic molecules. Moreover, as you saw in Section 13.2, the same intermolecular forces that dissolve smaller molecules stabilize these giant molecules in the aqueous medium of the cell.

## Sugars and Polysaccharides

In essence, the same chemical change occurs when you burn a piece of wood or eat a piece of bread. Wood and bread are mixtures of carbohydrates, substances that provide energy through oxidation.

Figure 15.26 The formation of nylon-66. Nylons are formed industrially by the reaction of diamine and diacid monomers. In this laboratory demonstration, the six-C diacid chloride, which is more reactive than the diacid, is used as one monomer; the polyamide forms between the two liquid phases.

A

Figure 15.27 The structure of glucose in aqueous solution and the formation of a disaccharide. A, A molecule of glucose undergoes an internal addition reaction between the aldehyde group of $\mathrm{C}-1$ and the alcohol group of $\mathrm{C}-5$ to form a cyclic monosaccharide. B, Two monosaccharides, glucose and fructose, undergo a dehydration-condensation reaction to form the disaccharide sucrose (table sugar) and a water molecule.

Polysaccharide Skeletons of Lobsters and Roaches The variety of polysaccharide properties that arises from simple changes in the monomers is amazing. For example, substituting an $-\mathrm{NH}_{2}$ group for the - OH group at $\mathrm{C}-2$ in glucose produces glucosamine. The amide that is formed from glucosamine and acetic acid ( N -acetylglucosamine) is the monomer of chitin (pronounced "KY-tin"), a polysaccharide that is the main component of the tough, brittle, external skeletons of insects and crustaceans.

Monomer Structure and Linkage Glucose and other simple sugars, from the three-C trioses to the seven-C heptoses, are called monosaccharides and consist of carbon chains with attached hydroxyl and carbonyl groups. In addition to their roles as individual molecules engaged in energy metabolism, they serve as the monomer units of polysaccharides. Most natural polysaccharides are formed fragofine and six-6 pnits Fl aqueous solution, an alcohol group and the aldehyde (or ketone) group of a given monosaccharide react with each other to form a cyclic molecule with either a five- or six-membered ring (Figure 15.27A).

When two monosaccharides undergo a dehydration-condensation reaction, a disaccharide forms. For example, sucrose (table sugar) is a disaccharide of glucose (linked at $\mathrm{C}-1$ ) and fructose (linked at $\mathrm{C}-2$ ) (Figure 15.27B); lactose (milk sugar) is a disaccharide of glucose ( $\mathrm{C}-1$ ) and galactose ( $\mathrm{C}-4$ ); and maltose, used in brewing and as a sweetener, is a disaccharide of two glucose units ( $\mathrm{C}-1$ to $\mathrm{C}-4$ ).
Types of Polysaccharides A polysaccharide consists of many monosaccharide units linked together. The three major natural polysaccharides - cellulose, starch, and glycogen-consist entirely of glucose units, but they differ in the ring positions of the links, in the orientation of certain bonds, and in the extent of crosslinking. Some other polysaccharides contain nitrogen in their attached groups.

Cellulose is the most abundant organic chemical on Earth. More than $50 \%$ of the carbon in plants occurs in the cellulose of stems and leaves; wood is largely cellulose, and cotton is more than $90 \%$ cellulose (see Section 13.2). Cellulose consists of long chains of glucose. The great strength of wood is due largely to the H bonds between cellulose chains. The monomers are linked in a particular way from C-1 in one unit to C-4 in the next. Humans lack the enzymes to break this link, so we cannot digest cellulose (unfortunately!); however, microorganisms in the digestive tracts of some animals, such as cows, sheep, and termites, can.

Starch is a mixture of polysaccharides of glucose and serves as an energy store in plants. When a plant needs energy, some starch is broken down by hydrolysis of the bonds between units, and the released glucose is oxidized through a multistep metabolic pathway. Starch occurs in plant cells as insoluble granules of amylose, a helical molecule of several thousand glucose units, and amylopectin, a highly branched, bushlike molecule of up to a million glucose units. Most of the glucose units are linked by $\mathrm{C}-1$ to $\mathrm{C}-4$ bonds, as in cellulose, but a different
orientation around the chiral $\mathrm{C}-1$ allows our digestive enzymes to break starch down into monomers. A C-6 to C-1 crosslink joins chains every 24 to 30 units.

Glycogen functions as the energy storage molecule in animals. It occurs in liver and muscle cells as large, insoluble granules consisting of glycogen molecules made from 1000 to more than 500,000 glucose units. In glycogen, the units are also linked by $\mathrm{C}-1$ to $\mathrm{C}-4$ bonds, but the molecule is more highly crosslinked than starch, with C-6 to C-1 crosslinks every 8 to 12 units.

## Amino Acids and Proteins

As you saw in Section 15.5, synthetic polyamides (such as nylon-66) are formed from two monomers, one with a carboxyl group at each end and the other with an amine group at each end. Proteins, the polyamides of nature, are unbranched polymers formed from monomers called amino acids. As we discussed in Section 13.2, each amino acid has a carboxyl group and an amine group.
Monomer Structure and Linkage An amino acid has both its carboxyl group and its amine group attached to the $\alpha$-carbon, the second C atom in the chain. Proteins are made up of about 20 different types of amino acids, each with its own particular R group, ranging from an H atom to a polycyclic N -containing aromatic structure (Figure 15.28).

Figure 15.28 The common amino
acids. About 20 different amino acids occur in proteins. The R groups are screened gray, and the $\alpha$-carbons (boldface), with carboxyl and amino groups, are screened yellow. Here the amino acids are shown with the charges they have under physiological conditions. They are grouped by polarity, acid-base character, and presence of an aromatic ring. The $R$ groups play a major role in the shape and function of the protein.

In the aqueous cell fluid, the $\mathrm{NH}_{2}$ and COOH groups of amino acids are charged because the carboxyl group transfers an $\mathrm{H}^{+}$ion to $\mathrm{H}_{2} \mathrm{O}$ to form $\mathrm{H}_{3} \mathrm{O}^{+}$, which transfers the $\mathrm{H}^{+}$to the amine group. The overall process is, in effect, an intramolecular acid-base reaction:

gives

An H atom is the third group bonded to the $\alpha$-carbon, and the fourth is the R group (also called the side chain).

Each amino acid is linked to the next through a peptide (amide) bond formed by a dehydration-condensation reaction in which the carboxyl group of one monomer reacts with the amine group of the next. Therefore, as noted in Section 13.2, the polypeptide chain-the backbone of the protein-has a repeating structure that consists of an $\alpha$-carbon bonded to an amide group bonded to the next $\alpha$-carbon bonded to the next amide group, and so forth (see Figure 13.6, p. 508). The various R groups dangle from the $\alpha$-carbons on alternate sides of the chain.
The Hierarchy of Protein Structure Each type of protein has its own amino acid composition, a specific number and proportion of various amino acids. However, it is not the composition that defines the protein's role in the cell; rather, the sequence of amino acids determines the protein's shape and function. Proteins range from about 50 to several thousand amino acids, yet from a purely mathematical point of view, even a small protein of 100 amino acids has a virtually limitless number of possible sequences of the 20 types of amino acids $\left(20^{100} \approx\right.$ $10^{130}$. In fact, though, only a tiny fraction of these possibilities occur in actual protenin. ©op example, eventin an orgafism as complex as a human being, there are only about $10^{5}$ different types of protein.

A protein folds into its native shape as it is being synthesized in the cell. Some shapes are simple-long rods or undulating sheets. Others are far more complex-baskets, Y shapes, spheroid blobs, and countless other globular forms. Biochemists define a hierarchy for the overall structure of a protein (Figure 15.29):

Figure 15.29 The structural hierarchy of proteins. A typical protein's structure can be viewed at different levels. Primary structure (shown as a long string of balls leaving and returning to the picture frame) is the sequence of amino acids. Secondary structure consists of highly ordered regions that occur as an $\alpha$-helix or a $\beta$-sheet. Tertiary structure combines these regions with random coil sections. In many proteins, several tertiary units interact to give the quaternary structure.

1. Primary $\left(1^{\circ}\right)$ structure, the most basic level, refers to the sequence of covalently bonded amino acids in the polypeptide chain.
2. Secondary $\left(2^{\circ}\right)$ structure refers to sections of the chain that, as a result of $H$ bonding between nearby peptide groupings, adopt shapes called $\alpha$-helices and $\beta$-pleated sheets.
3. Tertiary $\left(3^{\circ}\right)$ structure refers to the three-dimensional folding of the whole polypeptide chain. In some proteins, certain folding patterns form characteristic regions that play a role in the protein's function-binding a hormone, attaching to a membrane, forming a polar channel, and so forth.
4. Quaternary $\left(4^{\circ}\right)$ structure, the most complex level, occurs in proteins made up of several polypeptide chains (subunits) and refers to the way the chains assemble into the overall protein.
Note that only the $1^{\circ}$ structure involves covalent bonds; the $2^{\circ}, 3^{\circ}$, and $4^{\circ}$ structures rely primarily on intermolecular forces, as discussed in Section 13.2.

The Relation Between Structure and Function Two broad classes of proteins differ in the complexity of their amino acid compositions and sequences and, therefore, in their structure and function:

1. Fibrous proteins have relatively simple amino acid compositions and correspondingly simple structures. They are key components of hair, wool, skin, and connective tissue-materials that require strength and flexibility. Like synthetic polymers, these proteins have a small number of different amino acids in a repeating sequence. Consider collagen, the most common animal protein, which makes up as much as $40 \%$ of human body weight. More than $30 \%$ of its amino acids are glycine ( G ) and another $20 \%$ are proline ( P ). It exists as three chains, each an extended helix, that wind tightly around each other as the peptide $\mathrm{C}=\mathrm{O}$ groups in one chain form H bonds to the pende ger grous in anotherate cesilis a long, triple-helical cable with the sequence $-\mathrm{G}-\mathrm{X}-\mathrm{P}-\mathrm{G}-\mathrm{X}-\mathrm{P}-$ and so on (where X is another amino acid), as shown in Figure 15.30A. As the main component of tendons, skin, and blood vessels, collagen has a high tensile strength; in fact, a $1-\mathrm{mm}$ thick strand can support a $10-\mathrm{kg}$ weight!

In silk fibroin, secreted by the silk moth caterpillar, more than $85 \%$ of the amino acids are glycine, alanine, and serine (Figure 15.30B). Fibroin chain segments bend back and forth, running alongside each other, and form interchain H bonds to create a pleated sheet. Stacks of sheets interact through dispersion forces, which make fibroin strong and flexible but not very extendable-perfect for a silkworm's cocoon.
2. Globular proteins have much more complex compositions, often containing all 20 amino acids in varying proportions. As the name implies, globular proteins are typically more rounded and compact, with a wide variety of shapes and a correspondingly wide range of functions: defenders against bacterial invasion, messengers that trigger cell actions, catalysts of chemical change, membrane gatekeepers that maintain aqueous concentrations, and many others. The locations of particular amino-acid R groups are crucial to the protein's function. For example, in catalytic proteins, a few R groups form a crevice that closely matches the shapes of reactant molecules. These groups typically hold the reactants through intermolecular forces and speed their reaction to products by bringing them together and twisting and stretching their bonds. Experiment has shown repeatedly that a slight change in one of these critical R groups decreases function dramatically. This fact supports the essential idea that the protein's amino acid sequence determines its structure, which in turn determines its function:

$$
\text { SEQUENCE } \Longrightarrow \text { STRUCTURE } \Longrightarrow \text { FUNCTION }
$$

Next, we'll see how the amino acid sequence of every protein in every organism is prescribed by the genetic information that is held within the organism's nucleic acids.

Figure 15.30 The shapes of fibrous proteins. Fibrous proteins have largely structural roles in an organism, and their amino acid sequence is relatively simple. A, The triple helix of a collagen molecule has a glycine as every third amino acid along the chain. B, The pleated sheet structure of silk fibroin has a repeating sequence of glycine alternating with either alanine or serine. The sheets interact through dispersion forces.

## Nucleotides and Nucleic Acids

An organism's nucleic acids construct its proteins. And, given that the proteins determine how the organism looks and behaves, no job could be more essential.
Monomer Structure and Linkage Nucleic acids are unbranched polymers that consist of linked monomer units called mononucleotides, which consist of an N -containing base, a sugar, and a phosphate group. The two types of nucleic acid, ribonucleic acid (RNA) and deoxyribonucleic acid (DNA), differ in the sugar portions of their mononucleotides. RNA contains ribose, a five-C sugar, and DNA contains deoxyribose, in which -H substitutes for -OH on the $2^{\prime}$ position of ribose. (Carbon atoms in the sugar portion are given numbers with a prime to distinguish them from carbon atoms in the base.)

The cellular precursors that form a nucleic acid are nucleoside triphosphates (Figure 15.31A). Dehydration-condensation reactions between them release inorganic diphosphate $\left(\mathrm{H}_{2} \mathrm{P}_{2} \mathrm{O}_{7}{ }^{2-}\right)$ and create phosphodiester bonds to form a polynucleotide chain. Therefore, the repeating pattern of the nucleic acid backbone is -sugar - phosphate - sugar - phosphate - , and so on (Figure 15.31B). Attached to each sugar is one of four N -containing bases, either a pyrimidine (six-membered ring) or a purine (six- and five-membered rings sharing a side). The pyrimidines are thymine $(\mathrm{T})$ and cytosine $(\mathrm{C})$; the purines are guanine $(\mathrm{G})$ and adenine $(\mathrm{A})$; in RNA, uracil (U) substitutes for thymine. The bases dangle off the sugar-phosphate chain, much as R groups dangle off the polypeptide chain of a protein.

Figure 15.31 Nucleic acid precursors and their linkage. A, In the cell, nucleic acids are constructed from nucleoside triphosphates, precursors of the mononucleotide units. Each one consists of an N -containing base (structure not shown), a sugar, and a triphosphate group. In RNA (top), the sugar is ribose; in DNA, it is $2^{\prime}$-deoxyribose (note the absence of an -OH group on $\mathrm{C}-2$ of the ring). $\mathbf{B}$, A tiny segment of the polynucleotide chain of DNA (with one, mononucleotide unit boxed) shows the phosphodiester bonds that link the $5^{\prime}$ - OH group of one sugar to the $3^{\prime}-\mathrm{OH}$ group of the next and are formed through dehydrationcondensation reactions (which also release diphosphate ion). The bases dangle off the chain.

Figure 15.32 The double helix of DNA. A segment of DNA is shown as a space-filling model (left). The boxed area is expanded (center) to show how the polar sugar-phosphate asfe- backble faces the watery outside, and the nonpolar bases form H bonds to each
other in the DNA core. The boxed area is expanded (right) to show how a pyrimidine and a purine always form H -bonded base pairs to maintain
Findambleneleidth. The members of the pairs are always the same: A pairs with T , and G pairs with C .

The Central Importance of Base Pairing In the nucleus of the cell, DNA exists as two chains wrapped around each other in a double helix (Figure 15.32). Each base in one chain "pairs" with a base in the other through H bonding. A doublehelical DNA molecule may contain many millions of H -bonded bases in specified pairs. Two features of these base pairs are crucial to the structure and function of DNA:

- A pyrimidine and a purine are always paired, which gives the double helix a constant diameter.
- Each base is always paired with the same partner: A with T and G with C. Thus, the base sequence on one chain is the complement of the sequence on the other. For example, the sequence $\mathrm{A}-\mathrm{C}-\mathrm{T}$ on one chain is always paired with $\mathrm{T}-\mathrm{G}-\mathrm{A}$ on the other: A with $\mathrm{T}, \mathrm{C}$ with G , and T with A .

Each DNA molecule is folded into a tangled mass that forms one of the cell's chromosomes. The DNA molecule is amazingly long and thin: if the largest human chromosome were stretched out, it would be 4 cm long; in the cell nucleus, however, it is wound into a structure only 5 nm long-8 million times shorter! Segments of the DNA chains are the genes that contain the chemical information for synthesizing the organism's proteins.
An Outline of Protein Synthesis The information content of a gene resides in its base sequence. In the genetic code, each base acts as a "letter," each three-base sequence as a "word," and each word codes for a specific amino acid. For example, the sequence $\mathrm{C}-\mathrm{A}-\mathrm{C}$ codes for the amino acid histidine, $\mathrm{A}-\mathrm{A}-\mathrm{G}$ codes for lysine, and so on. Through a complex series of interactions, greatly simplified

Figure 15.33 Key stages in protein synthesis.
 to the next in the process of protein synthesis. To fully appreciate this aspect of the chemical basis of biology, keep in mind that this amazingly complex process occurs largely through H bonding between base pairs.

Here is an outline of protein synthesis. DNA occurs in the cell nucleus, but the genetic message is decoded outside it, so the information must be sent to the synthesis site. RNA serves in this messenger role, as well as in several others. A portion of the DNA is temporarily unwound and one chain segment acts as a template for the formation of a complementary chain of messenger RNA (mRNA) made by individual mononucleoside triphosphates linking together; thus, the DNA code words are transcribed into RNA code words through base pairing. The mRNA leaves the nucleus and binds, again through base pairing, to an RNA-rich particle in the cell called a ribosome. The words (three-base sequences) in the mRNA are then decoded by molecules of transfer RNA (tRNA). These smaller nucleic acid "shuttles" have two key portions on opposite ends of their structures:

- A three-base sequence that is the complement of a word on the mRNA
- A binding site for the amino acid coded by that word

The ribosome moves along the bound mRNA, one word at a time, while tRNAs bind to the mRNA and position their amino acids near one another in preparation for peptide bond formation and synthesis of the protein.

In essence, then, protein synthesis involves the DNA message of three-base words being transcribed into the RNA message of three-base words, which is then translated into a sequence of amino acids that are linked to make a protein:

## DNA BASE SEQUENCE $\Rightarrow$ RNA BASE SEQUENCE $\Rightarrow$ PROTEIN AMINO ACID SEQUENCE

An Outline of DNA Replication Another complex series of interactions allows DNA replication, the ability of DNA to copy itself. When a cell divides, its chromosomes are replicated, or reproduced, ensuring that the new cells have the same number and types of chromosomes. In this process, a small portion of the double helix is

Figure 15.34 Key stages in DNA replication.
"unzipped," and each DNA chain acts as a template for the base pairing of its mononucleotide monomers with free mononucleoside triphosphates (Figure 15.34). These new units, H -bonded to their complements, are linked through phosphodiester bonds into a chain by an enzyme called DNA polymerase. Gradually, each of the unzipped chains forms the complementary half of a double helix, leading to two double helices. Because each base always pairs with its complement, the original double helix is copied and the genetic makeup of the cell preserved. (Base pairing is central to methods for learning the sequence of nucleotides in our genes, as the upcoming Chemical Connections esaysaos. PDF Enhancer

The biopolymers provide striking evidence for the folly of vitalism-that some sort of vital force exists only in substances from living systems. No unknowable force is required to explain the marvels of the living world. The same atomic properties that give rise to covalent bonds, molecular shape, and intermolecular forces provide the means for all life forms to flourish.

## Section Summary

The three types of natural polymers-polysaccharides, proteins, and nucleic acids-are formed by dehydration-condensation reactions. - Polysaccharides are formed from cyclic monosaccharides, such as glucose. Cellulose, starch, and glycogen have structural or energy-storage roles. - Proteins are polyamides formed from as many as 20 different types of amino acids. Fibrous proteins have extended shapes and play structural roles. Globular proteins have compact shapes and play metabolic, immunologic, and hormonal roles. The amino acid sequence of a protein determines its shape and function. - Nucleic acids (DNA and RNA) are polynucleotides consisting of four different mononucleotides. The base sequence of the DNA chain determines the sequence of amino acids in an organism's proteins. Hydrogen bonding between specific base pairs is the key to protein synthesis and DNA replication. - DNA sequencing is used to determine the identity and order of nucleotides; DNA fingerprinting is used to identify a person from the characteristic pattern of gene fragments in a sample of cells.

## Chapter Perspective

The amazing diversity of organic compounds highlights the importance of atomic properties. While gaining an appreciation for the special properties of carbon, you've seen similar types of bonding, molecular shapes, intermolecular forces, and reactivities in organic and inorganic compounds. Upcoming chapters focus on the dynamic aspects of all reactions-their speed, extent, and direction-as we explore the kinetics, equilibrium, and thermodynamics of chemical and physical change. We'll have many opportunities to exemplify these topics with organic compounds and biochemical systems.

## DNA Sequencing and Fingerprinting

As a result of one of the most remarkable achievements in modern science, we now know the sequence of the 3 billion nucleotide base pairs in the DNA of the entire human genome! The genome consists of DNA molecules; segments of their chains are the genes, the functional units of heredity. The DNA exists in each cell's nucleus as tightly coiled threads arranged, in the human, into 23 pairs of chromosomes (Figure B15.6). The potential benefits of this knowledge are profound, and central to the accomplishment is DNA sequencing, the process used to determine the identity and order of bases. Sequencing is indispensable to molecular biology and biochemical genetics.

Just as indispensable to forensic science is DNA fingerprinting (or DNA profiling), a different process but one that employs some similar methods. In 1985, British scientists discovered that portions of an individual's DNA are as unique as fingerprints. The technique has been applied in countless situations, from parental custody claims to crime scene investigations to identifying the remains of victims of the September 11, 2001, terrorist attacks.

## An Outline of DNA Sequencing

A given chromosome may have 100 million nucleotide bases, but the sequencing process can handle, at one time, DNA fragments only about 2000 bases long. Therefore, the chromosome is first broken into pieces by enzymes that cleave at specific sites. Then, to obtain enough sample for analysis, the DNA is replicated through a variety of "amplification" methods, which make many copies of the individual DNA "target" fragmento

The most popular sequencing method is the Sanger chaintermination method, which uses chemically altered bases to stop the growth of a complementary DNA chain at specific locations. As you've seen in the previous text discussion, the chain consists of linked $2^{\prime}$-deoxyribonucleoside monophosphate units (dNMP, where N represents $\mathrm{A}, \mathrm{T}, \mathrm{G}$, or C ). The link is a phosphodiester bond from the $3^{\prime}-\mathrm{OH}$ of one unit to the $5^{\prime}-\mathrm{OH}$ of the next. The free

Figure B15.6 DNA, the genetic material. In the cell nucleus, each chromosome consists of a DNA molecule wrapped around globular proteins called histones. Segments of the DNA chains are genes.
monomers used to construct the chain are $2^{\prime}$-deoxyribonucleoside triphosphates (dNTP) (Figure B15.7A). The Sanger method uses a modified monomer, called a dideoxyribonucleoside triphosphate (ddNTP), in which the $3^{\prime}-\mathrm{OH}$ group is also missing from the ribose unit (Figure B15.7B). As soon as the ddNTP is incorporated into the growing chain, polymerization stops because there is no - OH group on the $3^{\prime}$ position to form a phosphodiester bond to the next dNTP unit.

The procedure is shown in Figure B15.8. After several preparation steps, the sample to be sequenced consists of a singlestranded DNA target fragment, which is attached to one strand of a double-stranded segment of DNA (Figure B15.8A). This sample is divided into four tubes, and to each tube is added a mixture of DNA polymerase, large amounts of all four dNTP's, and a small amount of one of the four ddNTP's. Thus, tube 1 contains polymerase, dATP, dGTP, dCTP, and dTTP, and, say, ddATP; tube 2 contains the same, except ddGTP instead of ddATP; and so forth. After the polymerization reaction is complete, each tube contains the original target fragment paired to complementary chains of varying length (Figure B15.8B). The chain lengths vary because in tube 1, each complementary chain ends in ddA (designated $\mathbf{A}$ in the figure); in tube 2, each ends in ddG (G); in tube 3, each ends in ddC (C); and in tube 4, each ends in ddT (T).

Each double-stranded product is divided into single strands, and then the complementary chains are separated by means of high-resolution polyacrylamide-gel electrophoresis. This technique applies an electric field to separate charged species through differenes intheratef migration through pores in a gel: the smaller the species, the faster it moves. Polynucleotide fragments are commonly separated by electrophoresis because they have charged phosphate groups. High-resolution gels can be made with pores that vary so slightly in size that they can separate fragments differing by only a single nucleotide.

In this step, each sample is applied to its own "lane" on a gel, and, after electrophoresis, the gel is scanned to locate the chains,

Figure B15.7 Nucleoside triphosphate monomers. The normal deoxy monomer (dNTP; top) has no $2^{\prime}-\mathrm{OH}$ group but does have a $3^{\prime}-\mathrm{OH}$ group to continue growth of the polynucleotide chain. The modified dideoxy monomer in the Sanger method (ddNTP; bottom) also lacks the $3^{\prime}-\mathrm{OH}$ group.

which appear in bands. Because all four ddNTP's were used, all possible chain fragments are formed, so the sequence of the original DNA fragment can be determined (Figure B15.8C).

An automated approach begins with each ddNTP tagged with a different fluorescent dye that emits light of a distinct color. The entire mixture of complementary chains is introduced onto the gel and separated. The gel is scanned by a laser, which activates the dyes. The fluorescent intensity versus distance along the chain is detected and plotted by a computer (Figure B15.8D).

## An Outline of DNA Fingerprinting

Biological samples collected at a crime scene are often very small, so, as with sequencing, the first step to obtain enough DNA for forensic analysis involves amplification. Modern techniques require less than 1 ng of DNA. Thus, in addition to blood and semen, licked stamps and envelopes, gum, and clothing containing dead skin cells can also be used as sources for the DNA.

Currently, the most successful and widely used DNA profiling procedure is called short tandem repeat (STR) analysis. STRs are specific areas on a chromosome that contain short (3-7 bases) sequences that repeat themselves within the DNA molecule. There are hundreds of different types of STRs, but each person has a unique number and assortment of types. Therefore, the more STRs that are characterized, the more discriminating the analysis. EOnce the STR ahave been amplified, they are separated by electrophoresis, and an analyst determines the number of base repeats within each STR (Figure B15.9).

Figure B15.9 STR analysis of DNA in a blood stain. Stained gels containing the STRs of DNA in blood samples from several suspects are compared with those from the blood found at the crime scene. Suspect 3 has an identical pattern of STRs to those in the blood stain.

## CHAPTER REVIEW GUIDE The following sections provide many aids to help you study this chapter.

 (Numbers in parentheses refer to pages, unless noted otherwise.)
## Learning Objectives These are concepts and skills you should know after studying this chapter.

Relevant section and/or sample problem (SP) numbers appear in parentheses.

## Understand These Concepts

1. How carbon's atomic properties give rise to its ability to form four strong covalent bonds, multiple bonds, and chains, which results in the great structural diversity of organic compounds (15.1) 2. How carbon's atomic properties give rise to its ability to bond to various heteroatoms, which creates regions of charge imbalance that result in functional groups (15.1)
2. Structures and names of alkanes, alkenes, and alkynes (15.2)
3. The distinctions among constitutional, optical, and geometric isomers (15.2)
4. The importance of optical isomerism in organisms (15.2)
5. The effect of restricted rotation around a $\pi$ bond on the structures and properties of alkenes (15.2)
6. The nature of organic addition, elimination, and substitution reactions (15.3)
7. The properties and reaction types of the various functional groups (15.4):

- Substitution and elimination for alcohols, alkyl halides, and amines
- Addition for alkenes, alkynes, and aldehydes and ketones
- Substitution for the carboxylic acid family (acids, esters, and amides)

9. Why delocalization of electrons causes arontifaigs ho heDE lower reactivity than alkenes (15.4)
10. The polarity of the carbonyl bond and the importance of organometallic compounds in addition reactions of carbonyl compounds (15.4)
11. How addition plus elimination lead to substitution in the reactions of the carboxylic acid family (15.4)
12. How addition and condensation polymers form (15.5)
13. The three types of biopolymers and their monomers (15.6)
14. How amino acid sequence determines protein shape, which determines function (15.6)
15. How complementary base pairing controls the processes of protein synthesis and DNA replication (15.6)
16. How DNA base sequence determines RNA base sequence, which determines amino acid sequence (15.6)

## Master These Skills

1. Drawing hydrocarbon structures given the number(s) of C atoms, multiple bonds, and rings (SP 15.1)
2. Naming hydrocarbons and drawing expanded, condensed, and carbon skeleton formulas (15.2 and SP 15.2)
3. Drawing geometric isomers and identifying chiral centers of molecules (SP 15.2)
4. Recognizing the type of reaction from the structures of reactants and products (SP 15.3)
5. Recognizing a reaction as an oxidation or reduction from the structures of reactants and products (15.3)
6. Determining the reactants and products of the reactions of alcohols, alkyl halides, and amines (SP 15.4 and Follow-up)
7. Determining the products in a stepwise reaction sequence (SP 15.5)
8. Determining the reactants of the reactions of aldehydes and ketones (Follow-up Problem 15.5)
9. Determining the reactants and products of the reactions of the carbexylie actlfaffly(SP 15.6 and Follow-up)
10. Recognizing and naming the functional groups in an organic molecule (SP 15.7)
11. Drawing an abbreviated synthetic polymer structure based on monomer structures (15.5)
12. Drawing small peptides from amino acid structures (15.6)
13. Using the base-paired sequence of one DNA strand to predict the sequence of the other (15.6)

## PROBLEMS

Problems with colored numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and provide the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

## The Special Nature of Carbon and the Characteristics of Organic Molecules

## - Concept Review Questions

15.1 Give the names and formulas of two carbon compounds that are organic and two that are inorganic.
15.2 Through the first quarter of the $19^{\text {th }}$ century, the concept of vitalism—that a key difference existed between substances isolated from animate sources and those from inanimate sourceswas widely accepted. What was the central notion of vitalism? Give an example of a finding that led to its eventual downfall.
15.3 Explain each statement in terms of atomic properties:
(a) Carbon engages in covalent rather than ionic bonding.
(b) Carbon has four bonds in all its organic compounds.
(c) Carbon forms neither stable cations, like many metals, nor stable anions, like many nonmetals.
(d) Carbon bonds to itself more extensively than does any other element.
(e) Carbon forms stable multiple bonds.
15.4 Carbon bonds to many elements other thañ tiself. 90
(a) Name six elements that commonly bond to carbon in organic compounds.
(b) Which of these elements are heteroatoms?
(c) Which of these elements are more electronegative than carbon? Less electronegative?
(d) How does bonding of carbon to heteroatoms increase the number of organic compounds?
15.5 Silicon lies just below carbon in Group 4A(14) and also forms four covalent bonds. Why aren't there as many silicon compounds as carbon compounds?
15.6 What is the range of oxidation states for carbon? Name a compound in which carbon has its highest oxidation state and one in which it has its lowest.
15.7 Which of these bonds to carbon would you expect to be relatively reactive: $\mathrm{C}-\mathrm{H}, \mathrm{C}-\mathrm{C}, \mathrm{C}-\mathrm{I}, \mathrm{C}=\mathrm{O}, \mathrm{C}-\mathrm{Li}$ ? Explain.

## The Structures and Classes of Hydrocarbons

(Sample Problems 15.1 and 15.2)

## - Concept Review Questions

15.8 (a) What structural feature is associated with each type of hydrocarbon: an alkane; a cycloalkane; an alkene; an alkyne?
(b) Give the general formula for each type.
(c) Which hydrocarbons are considered saturated?
15.9 Define each type of isomer: (a) constitutional; (b) geometric; (c) optical. Which types of isomers are stereoisomers?
15.10 Among alkenes, alkynes, and aromatic hydrocarbons, only alkenes exhibit cis-trans isomerism. Why don't the others?
15.11 Which objects are asymmetric (have no plane of symmetry): (a) a circular clock face; (b) a football; (c) a dime; (d) a brick; (e) a hammer; (f) a spring?
15.12 Explain how a polarimeter works and what it measures.
15.13 How does an aromatic hydrocarbon differ from a cycloalkane in terms of its bonding? How does this difference affect structure?

Skill-Building Exercises (grouped in similar pairs)
15.14 Draw all possible skeletons for a 7-C compound with
(a) A 6-C chain and 1 double bond
(b) A 5-C chain and 1 double bond
(c) A 5-C ring and no double bonds
15.15 Draw all possible skeletons for a 6-C compound with
(a) A 5-C chain and 2 double bonds
(b) A 5-C chain and 1 triple bond
(c) A 4-C ring and no double bonds
15.16 Add the correct number of hydrogens to each of the skeletons in Problem 15.14.
15.17 Add the correct number of hydrogens to each of the skeletons in Problem 15.15.
15.18 Draw correct structures, by making a single change, for any that are incorrect:
(a)

(b) $\mathrm{CH}_{3}=\mathrm{CH}-\mathrm{CH}_{2}-\mathrm{CH}_{3}$
(c) Fohticacmeers
(d)

15.19 Draw correct structures, by making a single change, for any that are incorrect:
(a)
(a) $\mathrm{CH}_{3}-\mathrm{CH}=\mathrm{CH}-\mathrm{CH}_{2}-\mathrm{CH}_{3}$
(b)

(d)

(c)

15.20 Draw the structure or give the name of each compound:
(a) 2,3-dimethyloctane
(b) 1-ethyl-3-methylcyclohexane
(c)

(d)

15.21 Draw the structure or give the name of each compound:
(a)

(b)

(c) 1,2-diethylcyclopentane
(d) 2,4,5-trimethylnonane
15.22 Each of the following names is wrong. Draw structures based on them, and correct the names:
(a) 4-methylhexane
(b) 2-ethylpentane
(c) 2-methylcyclohexane
(d) 3,3-methyl-4-ethyloctane
15.23 Each of the following names is wrong. Draw structures based on them, and correct the names:
(a) 3,3-dimethylbutane
(b) 1,1,1-trimethylheptane
(c) 1,4-diethylcyclopentane
(d) 1-propylcyclohexane
15.24 Each of the following compounds can exhibit optical activity. Circle the chiral center(s) in each:
(a)

(b)

15.25 Each of the following compounds can exhibit optical activity. Circle the chiral center(s) in each:
(a)

(b)

15.26 Draw structures from the following names, and determine which compounds are optically active:
(a) 3-bromohexane
(b) 3-chloro-3-methylpentane
(c) 1,2-dibromo-2-methylbutane
15.27 Draw structures from the following names, and determine
which compounds are optically active:
(a) 1,3-dichloropentane
(b) 3-chlo
fo-2,2,5-qumethy Pexane
(c) 1-bromo-1-chlorobutane
15.28 Which of the following structures exhibit geometric isomerism? Draw and name the two isomers in each case:
(a)

(b)
(c)

15.29 Which of the following structures exhibit geometric isomerism? Draw and name the two isomers in each case:
(a)

(b)

(c)

15.30 Which compounds exhibit geometric isomerism? Draw and name the two isomers in each case:
(a) propene
(b) 3-hexene
(c) 1,1-dichloroethene
(d) 1,2-dichloroethene
15.31 Which compounds exhibit geometric isomerism? Draw and name the two isomers in each case:
(a) 1-pentene
(b) 2-pentene
(c) 1-chloropropene
(d) 2-chloropropene
15.32 Draw and name all the constitutional isomers of dichlorobenzene.
15.33 Draw and name all the constitutional isomers of trimethylbenzene.

## Problems in Context

15.34 Butylated hydroxytoluene (BHT) is a common preservative added to cereals and other dry foods. Its systematic name is 1 -hydroxy-2,6-di-tert-butyl-4-methylbenzene (where "tert-butyl" is 1,1 -dimethylethyl). Draw the structure of BHT.
15.35 There are two compounds with the name 2-methyl-3-hexene, but only one with the name 2-methyl-2-hexene. Explain with structures.
15.36 Any tetrahedral atom with four different groups attached can be a chiral center. Which of these species is optically active?
(a) CHClBrF
(b) $\mathrm{NBrCl}_{2} \mathrm{H}^{+}$
(c) $\mathrm{PFClBrI}^{+}$
(d) SeFClBrH
15.37 The number of peaks in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of a compound depends on the number of different kinds (environments) of H atoms. How many peaks appear in the spectrum of each isomer of $\mathrm{C}_{4} \mathrm{H}_{10}$ and of $\mathrm{C}_{5} \mathrm{H}_{12}$ (see Table 15.3, p. 638)?

## Some Important Classes of Organic Reactions

(Sample Problem 15.3)

## Concept Review Questions

15.38 In terms of numbers of reactant and product substances, which organic reaction type corresponds to (a) a combination reaction, (b) a decomposition reaction, (c) a displacement reaction? 15.39 The same type of bond is broken in an addition reaction and formed in an elimination reaction. Name the type.
15.40 Can a redox reaction also be an addition, elimination, or substitution reaction? Explain with examples.

## EalsutuBailding Exercises (grouped in similar pairs)

 15.41 Determine the type of each of the following reactions:(a)

(b)

15.42 Determine the type of each of the following reactions:
(a)

(b)

15.43 Write equations for the following: (a) an addition reaction between $\mathrm{H}_{2} \mathrm{O}$ and 3-hexene ( $\mathrm{H}^{+}$is a catalyst); (b) an elimination reaction between 2-bromopropane and hot potassium ethoxide, $\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{OK}$ ( KBr and ethanol are also products); (c) a light-induced substitution reaction between $\mathrm{Cl}_{2}$ and ethane to form 1,1-dichloroethane.
15.44 Write equations for the following: (a) a substitution reaction between 2-bromopropane and KI; (b) an addition reaction between cyclohexene and $\mathrm{Cl}_{2}$; (c) an addition reaction between 2-propanone and $\mathrm{H}_{2}$ (Ni metal is a catalyst).
15.45 Based on the number of bonds and the nature of the bonded atoms, state whether each of the following changes is an oxidation or a reduction:
(a) $=\mathrm{CH}_{2}$ becomes $-\mathrm{CH}_{2}-\mathrm{OH}$
(b) $=\mathrm{CH}$ - becomes $-\mathrm{CH}_{2}$ -
(c) $\equiv \mathrm{C}$ - becomes $-\mathrm{CH}_{2}-$
15.46 Based on the number of bonds and the nature of the bonded atoms, state whether each of the following changes is an oxidation or a reduction:
(a)

(b) $-\mathrm{CH}_{2}-\mathrm{OH}$ becomes $=\mathrm{CH}_{2}$
(c)

15.47 Is the organic reactant oxidized, reduced, or neither in each of the following reactions?
(a) 2-hexene $\xrightarrow[\text { cold OH }]{\mathrm{KMnO}_{4}}$ 2,3-dihydroxyhexane
(b) cyclohexane $\xrightarrow[\text { catalyst }]{\Delta}$ benzene $+3 \mathrm{H}_{2}$
15.48 Is the organic reactant oxidized, reduced, or neither in each of the following reactions?
(a) 1-butyne $+\mathrm{H}_{2} \xrightarrow{\mathrm{Pt}}$ 1-butene
(b) toluene $\xrightarrow[\mathrm{H}_{3} \mathrm{O}^{+}, \Delta]{\mathrm{KMnO}_{4}}$ benzoic acid

## Problems in Context

15.49 Phenylethylamine is a natural substance that is structurally similar to amphetamine. It is found in sources as diverse as almond oil and human urine, where it occurs at elevated concentrations as a result of stress and certain forms of schizophrenia. One method of synthesizing the compound for phatnacologieal and psychiatric studies involves two steps:

Classify each step as an addition, elimination, or substitution.

## Properties and Reactivities of Common Functional Groups

(Sample Problems 15.4 to 15.7)

## - Concept Review Questions

15.50 Compounds with nearly identical molar masses often have very different physical properties. Choose the compound with the higher value for each of the following properties, and explain your choice.
(a) Solubility in water: chloroethane or methylethylamine
(b) Melting point: diethyl ether or 1-butanol
(c) Boiling point: trimethylamine or propylamine
15.51 Fill in each blank with a general formula for the type of compound formed:

15.52 Of the three major types of organic reactions, which do not occur readily with benzene? Why?
15.53 Why does the $\mathrm{C}=\mathrm{O}$ group react differently from the $\mathrm{C}=\mathrm{C}$ group? Show an example of the difference.
15.54 Many substitution reactions involve an initial electrostatic attraction between reactants. Show where this attraction arises in the formation of an amide from an amine and an ester.
15.55 Although both carboxylic acids and alcohols contain an - OH group, one is acidic in water and the other is not. Explain.
15.56 What reaction type is common to the formation of esters and acid anhydrides? What is the other product?
15.57 Both alcohols and carboxylic acids undergo substitution, but the processes are very different. Explain.

## Skill-Building Exercises (grouped in similar pairs)

15.58 Name the type of organic compound from the following description of its functional group: (a) polar group that has only single bonds and does not include O or N ; (b) group that is polar and has a triple bond; (c) group that has single and double bonds and is acidic in water; (d) group that has a double bond and must be at the end of a C chain.
15.59 Name the type of organic compound from the following description of its functional group: (a) N-containing group with single and double bonds; (b) group that is not polar and has a double bond; (c) polar group that has a double bond and cannot be at the end of a C chain; (d) group that has only single bonds and is basic in water.
15.60 Circle and name the functional group(s) in each compound:
(a) ${ }^{2} \mathrm{CH}_{3}$ han- $\mathrm{OHFOH}_{2}-\mathrm{OH}$
(b)

(c)

(d)

(e)

15.61 Circle and name the functional group(s) in each compound:
(a)

(c)

(b)
(d)

(e)

15.62 Draw all alcohols with the formula $\mathrm{C}_{5} \mathrm{H}_{12} \mathrm{O}$.
15.63 Draw all aldehydes and ketones with the formula $\mathrm{C}_{5} \mathrm{H}_{10} \mathrm{O}$.
15.64 Draw all amines with the formula $\mathrm{C}_{4} \mathrm{H}_{11} \mathrm{~N}$.
15.65 Draw all carboxylic acids with the formula $\mathrm{C}_{5} \mathrm{H}_{10} \mathrm{O}_{2}$.
15.66 Draw the product resulting from mild oxidation of (a) 2butanol; (b) 2-methylpropanal; (c) cyclopentanol.
15.67 Draw the alcohol you'd oxidize to produce (a) 2-methylpropanal; (b) 2-pentanone; (c) 3-methylbutanoic acid.
15.68 Draw the organic product formed when the following compounds undergo a substitution reaction: (a) acetic acid and
methylamine; (b) butanoic acid and 2-propanol; (c) formic acid and 2-methyl-1-propanol.
15.69 Draw the organic product formed when the following compounds undergo a substitution reaction: (a) acetic acid and 1-hexanol; (b) propanoic acid and dimethylamine; (c) ethanoic acid and diethylamine.
15.70 Draw condensed formulas for the carboxylic acid and alcohol that form the following esters:
(a)

(b)

(c)

15.71 Draw condensed formulas for the carboxylic acid and amine that form the following amides:
(a)

(b)

(c)

15.72 Fill in the expected organic substances:

## Apago PDF

(a)
 $\xrightarrow[\mathrm{H}^{+}]{\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{C}-\mathrm{OH}}$ $\qquad$
(b)

$\qquad$ $\xrightarrow{\mathrm{H}_{3} \mathrm{O}^{+}, \mathrm{H}_{2} \mathrm{O}}$ $\qquad$
15.73 Fill in the expected organic substances:
(a)

(b)

15.74 Supply the missing organic and/or inorganic substances:
(a)

(b)

15.75 Supply the missing organic and/or inorganic substances:
(a)

## Problems in Context

15.76 (a) Draw the four isomers of $\mathrm{C}_{5} \mathrm{H}_{12} \mathrm{O}$ that can be oxidized to an aldehyde. (b) Draw the three isomers of $\mathrm{C}_{5} \mathrm{H}_{12} \mathrm{O}$ that can be oxidized to a ketone. (c) Draw the isomers of $\mathrm{C}_{5} \mathrm{H}_{12} \mathrm{O}$ that cannot be easily oxidized to an aldehyde or ketone. (d) Name any isomer that is an alcohol.
15.77 Ethyl formate $\left(\stackrel{\mathrm{HC}}{\|}-\mathrm{O}-\mathrm{CH}_{2}-\mathrm{CH}_{3}\right)$ is added to foods to give them the flavor of rum. How would you synthesize ethyl formate from ethanol, methanol, and any inorganic reagents?

## The Monomer-Polymer Theme I: <br> Synthetic Macromolecules

## - Concept Review Questions

15.78 Name the reaction processes that lead to the two types of synthetic polymers.
15.79 Which functional group occurs in the monomers of addition polymers? How are these polymers different from one another?
15.80 What is a free radical? How is it involved in polymer formation?
15.81 Which intermolecular force is primarily responsible for the different types of polyethylene? Explain.
15.82 Which of the two types of synthetic polymer is more similar chemically to biopolymers? Explain.
15.83 Which functional groups react to form nylons? Polyesters?

## - Skill-Building Exercises (grouped in similar pairs)

15.84 Draw an abbreviated structure for the following polymers, with brackets around the repeat unit:

15.85 Draw an abbreviated structure for the following polymers, with brackets around the repeat unit:
(a) Teflon from
(b) Polystyrene from

## Problems in Context

15.86 Polyethylene terephthalate (PET) is used to make synthetic fibers, such as Dacron, thin films, such as Mylar, and bottles for carbonated beverages.

PET
PET is produced from ethylene glycol and either of two monomers, depending on whether the reaction proceeds by dehydration-condensation or by displacement. Write equations for the two syntheses. (Hint: The displacement is reversed by adding methanol to PET at high $T$ and $P$.)
15.87 Write a balanced equation for the reaction of dihydroxydimethylsilane (right) to form the condensation polymer known as Silly Putty.

## The Monomer-Polymer Theme II: Biological Macromolecules

## - Concept Review Questions

15.88 Which type of polymer is formed from each of the following monomers: (a) amino acids; (b) alkenes; (c) simple sugars; (d) mononucleotides?
15.89 What is the key structural difference between fibrous and globular proteins? How is it related, in general, to the proteins' amino acid composition?
15.90 Protein shape, function, and amino acid sequence are interrelated. Which determines which?
15.91 What linkage joins the monomers in each strand of DNA?
15.92 What is base pairing? How does it pertain to DNA structure? 15.93 RNA base sequence, protein amino acid sequence, and DNA base sequence are interrelated. Which determines which in the process of protein synthesis?

## Skill-Building Exercises (grouped in similar pairs)

15.94 Draw the R group of (a) alanine; (b) histidine; (c) methionine.
15.95 Draw the R group of (a) glycine; (b) isoleucine; (c) tyrosine.
15.96 Draw the structure of each of the following tripeptides:
(a) Aspartic acid-histidine-tryptophan
(b) Glycine-cysteine-tyrosine with the charges existing in cell fluid
15.97 Draw the structure of each of the following tripeptides:
(a) Lysine-phenylalanine-threonine
(b) Alanine-leucine-valine with the charges that exist in cell fluid
15.98 Write the sequence of the complementary DNA strand that pairs with each of the following DNA base sequences:
(a) TTAGCC
(b) AGACAT
15.99 Write the sequence of the complementary BAStrand that pairs with each of the following DNA base sequences:
(a) GGTTAC
(b) CCCGAA
15.100 Write the base sequence of the DNA template from which this RNA sequence was derived: UGUUACGGA. How many amino acids are coded for in this sequence?
15.101 Write the base sequence of the DNA template from which this RNA sequence was derived: GUAUCAAUGAACUUG. How many amino acids are coded for in this sequence?

## - Problems in Context

15.102 Protein shapes are maintained by a variety of forces that arise from interactions between the amino-acid R groups. Name the amino acid that possesses each R group and the force that could arise in each of the following interactions:
(a) $-\mathrm{CH}_{2}-\mathrm{SH}$ with $\mathrm{HS}-\mathrm{CH}_{2}-$
(b) $-\left(\mathrm{CH}_{2}\right)_{4}-\mathrm{NH}_{3}^{+}$
with

(c)

with $\mathrm{HO}-\mathrm{CH}_{2}$ -
(d)
 with

15.103 Amino acids have an average molar mass of $100 \mathrm{~g} / \mathrm{mol}$. How many bases on a single strand of DNA are needed to code for a protein with a molar mass of $5 \times 10^{5} \mathrm{~g} / \mathrm{mol}$ ?

## Comprehensive Problems

15.104 A synthesis of 2-butanol was performed by treating 2-bromobutane with hot sodium hydroxide solution. The yield
was $60 \%$, indicating that a significant portion of the reactant was converted into a second product. Predict what this other product might be. What simple test would support your prediction?
15.105 Ethers (general formula $\mathrm{R}-\mathrm{O}-\mathrm{R}^{\prime}$ ) have many important uses. Until recently, methyl tert-butyl ether (MTBE, right) was used as an octane booster and fuel additive for gasoline. It increases the oxygen content of the fuel, which reduces
 CO emissions. MTBE is synthesized by the catalyzed reaction of 2-methylpropene with methanol.
(a) Write a balanced equation for the synthesis of MTBE. (Hint: Alcohols add to alkenes similarly to the way water does.)
(b) If the government required that auto fuel mixtures contain $2.7 \%$ oxygen by mass to reduce CO emissions, how many grams of MTBE would have to be added to each 100. g of gasoline?
(c) How many liters of MTBE would be in each liter of fuel mixture? (The density of both gasoline and MTBE is $0.740 \mathrm{~g} / \mathrm{mL}$.)
(d) How many liters of air ( $21 \% \mathrm{O}_{2}$ by volume) are needed at $24^{\circ} \mathrm{C}$ and 1.00 atm to fully combust 1.00 L of MTBE?
15.106 An alcohol is oxidized to a carboxylic acid, and 0.2003 g of the acid is titrated with 45.25 mL of 0.03811 M NaOH . (a) What is the molar mass of the acid? (b) What are the molar mass and molecular formula of the alcohol?
15.107 Some of the most useful compounds for organic synthesis are Grignard reagents (general formula $\mathrm{R}-\mathrm{MgX}$, where X is a halogen), which are made by combining an alkyl halide, $\mathrm{R}-\mathrm{X}$, with Mg. They are used to change the carbon skeleton of a starting carbonyl compound in a reaction similar to that with $\mathrm{R}-\mathrm{Li}$ :

(a) What is the product, after a final step with water, of the reaction between ethanal and the Grignard reagent of bromobenzene? (b) What is the product, after a final step with water, of the reaction between 2-butanone and the Grignard reagent of 2-bromopropane? (c) There are often two (or more) combinations of Grignard reagent and carbonyl compound that will give the same product. Choose another pair of reactants to give the product in (a). (d) What carbonyl compound must react with a Grignard reagent to yield a product with the - OH group at the end of the carbon chain? (e) What Grignard reagent and carbonyl compound would you use to prepare 2-methyl-2-butanol?
15.108 Starting with the given organic reactant and any necessary inorganic reagents, explain how you would perform each of the following syntheses:
(a) From $\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{OH}$, make $\mathrm{CH}_{3}-\mathrm{CH}-\mathrm{CH}_{2}-\mathrm{Br}$
(b) From $\mathrm{CH}_{3}-\mathrm{CH}_{2}-\mathrm{OH}$, make $\mathrm{CH}_{3}-\stackrel{\mathrm{O}}{\mathrm{C}}-\mathrm{O}-\mathrm{CH}_{2}-\mathrm{CH}_{3}$
15.109 Compound A , composed of $\mathrm{C}, \mathrm{H}$, and O , is heated in a 1.00-L flask to $160 .{ }^{\circ} \mathrm{C}$ until all of the A has vaporized and displaced the air. The flask is then cooled, and 2.48 g of A remains. When 0.500 g of A burns in $\mathrm{O}_{2}, 0.409 \mathrm{~g}$ of $\mathrm{H}_{2} \mathrm{O}$ and 1.00 g of $\mathrm{CO}_{2}$ are produced. Compound A is not acidic, but it can be oxidized to compound B , which is weakly acidic: 1.000 g of B is
neutralized with 33.9 mL of 0.5 M sodium hydroxide. When B is heated to $260^{\circ} \mathrm{C}$, it gives off water and forms C , whose solution in $\mathrm{CDCl}_{3}$ (where D is deuterium, ${ }^{2} \mathrm{H}$ ) has one peak in its ${ }^{1} \mathrm{H}$-NMR spectrum. (a) What are the structures of $\mathrm{A}, \mathrm{B}$, and C ? (b) Compound A is a controlled substance because it is metabolized to the weakly acidic "date rape" drug GHB, $\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}_{3}$. What are the structure and name of GHB?
15.110 Cadaverine (1,5-diaminopentane) and putrescine (1,4diaminobutane) are two compounds that are formed by bacterial action and are responsible for the odor of rotting flesh. Draw their structures. Suggest a series of reactions to synthesize putrescine from 1,2-dibromoethane and any inorganic reagents.
15.111 Pyrethrins, such as jasmolin II (below), are a group of natural compounds synthesized by flowers of the genus Chrysanthemum (known as pyrethrum flowers) to act as insecticides.
(a) Circle and name the functional groups in jasmolin II.
(b) What is the hybridization of the numbered carbons?
(c) Which, if any, of the numbered carbons are chiral centers?

15.112 Compound A is branched and optically active and contains $\mathrm{C}, \mathrm{H}$, and O . (a) A $0.500-\mathrm{g}$ sample burns in excess $\mathrm{O}_{2}$ to yield 1.25 g of $\mathrm{CO}_{2}$ and 0.613 g of $\mathrm{H}_{2} \mathrm{O}$. Determine the empirical formula. (b) When 0.225 g of compound A vaporizes at 755 torr and $97^{\circ} \mathrm{C}$, the vapor occupies 78.0 mL ㄱetermine the molegtar formula. (c) Careful oxidation of the contpoundyields a ketone. Name and draw compound A, and circle the chiral center.
15.113 Ibuprofen is one of the most common anti-inflammatory drugs. (a) Identify the functional group(s) and chiral center(s) in ibuprofen. (b) Write a four-step synthesis of a racemic mixture of ibuprofen from 4-isobutylbenzaldehyde, using inorganic reactants and one organometallic reactant (see Problem 15.107).

15.114 Combustion of gasoline releases almost all of the carbon it contains as $\mathrm{CO}_{2}$, the major greenhouse gas. As a simplification, assume that gasoline consists of eight-C alkanes (average $d=0.74 \mathrm{~g} / \mathrm{mL}$ ). How many metric tons of $\mathrm{CO}_{2}$ are released in a year by an SUV that gets 15 mpg and is driven 18,000 miles?
15.115 Which features of retinal make it so useful as a photon absorber in the visual systems of organisms?
15.116 The polypeptide chain in proteins does not exhibit free rotation because of the partial double-bond character of the peptide bond. Explain this fact with resonance structures.
15.117 Other nonmetals form compounds that are structurally analogous to those of carbon, but these inorganic compounds are usually more reactive. Predict any missing products and write balanced equations for each reaction: (a) the decomposition and chlorination of diborane to boron trichloride; (b) the combustion of pentaborane $\left(\mathrm{B}_{5} \mathrm{H}_{9}\right)$ in $\mathrm{O}_{2}$; (c) the addition of water to bor-
azine's double bonds $\left(\mathrm{B}_{3} \mathrm{~N}_{3} \mathrm{H}_{6}\right.$, Figure 14.9B, p. 583) (Hint: The -OH group bonds to B ); (d) the hydrolysis of trisilane $\left(\mathrm{Si}_{3} \mathrm{H}_{8}\right)$ to silica $\left(\mathrm{SiO}_{2}\right)$ and $\mathrm{H}_{2}$; (e) the complete halogenation of disilane with $\mathrm{Cl}_{2}$; (f) the thermal decomposition of $\mathrm{H}_{2} \mathrm{~S}_{5}$ to hydrogen sulfide and sulfur molecules; (g) the hydrolysis of $\mathrm{PCl}_{5}$.
15.118 The genetic code consists of a series of three-base words that each code for a given amino acid.
(a) Using the selections from the genetic code shown below, determine the amino acid sequence coded by the following segment of RNA: UCCACAGCCUAUAUGGCAAACUUGAAG

| AUG $=$ methionine | CCU $=$ proline | CAU $=$ histidine |
| :--- | :--- | :--- |
| UGG $=$ tryptophan | AAG $=$ lysine | UAU $=$ tyrosine |
| GCC $=$ alanine | UUG $=$ leucine | CGG $=$ arginine |
| UGU $=$ cysteine | AAC $=$ asparagine | ACA $=$ threonine |
| UCC $=$ serine | GCA $=$ alanine | UCA $=$ serine |

(b) What is the complementary DNA sequence from which this RNA sequence was made? (c) If you were sequencing the DNA fragment in part (b), how many complementary chain pieces would you obtain in the tube containing ddATP?
15.119 In addition to their use in water treatment, ion-exchange resins are used to extract $\mathrm{Au}, \mathrm{Ag}$, and Pt ions from solution. One of the most common resins consists of a polymer with a benzene-containing backbone to which sulfonic acid groups $\left(-\mathrm{SO}_{3} \mathrm{H}\right)$ are then added. (a) What monomer can be used to prepare the polymer backbone? (b) This polymer typically contains $4-16 \%$ crosslinking. Draw the structure of the benzenecontaining monomer used to crosslink the polymer.
15.120 Complete hydrolysis of a $100.00-\mathrm{g}$ sample of a peptide F gave the following amounts of individual amino acids (molar Enhasses, in g/mof, appear in parentheses):
3.00 g of glycine (75.07)
0.90 g of alanine (89.10)
3.70 g of valine (117.15)
6.90 g of proline (115.13)
7.30 g of serine (105.10)
86.00 g of arginine (174.21)
(a) Why does the total mass of amino acids exceed the mass of peptide? (b) What are the relative numbers of amino acids in the peptide? (c) What is the minimum molar mass of the peptide?
15.121 Aircraft de-icing agents, such as propylene glycol [1,2propanediol; $\mathrm{CH}_{3} \mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{2} \mathrm{OH} ; d=1.036 \mathrm{~g} / \mathrm{mL}$ ], are used to remove ice and snow prior to winter flights, but their presence in runoff depletes $\mathrm{O}_{2}$ in natural waters. (a) Write a balanced equation for the complete oxidation of propylene glycol by $\mathrm{O}_{2}$. (b) What is the "theoretical oxygen demand," in grams of $\mathrm{O}_{2}$ required per gram of propylene glycol oxidized? (c) What is the theoretical oxygen demand, in grams of $\mathrm{O}_{2}$ required per liter of solution, of $90.0 \%$ by volume aqueous propylene glycol?
15.122 2-Butanone is reduced by hydride ion donors, such as sodium borohydride $\left(\mathrm{NaBH}_{4}\right)$, to the alcohol 2-butanol. Even though the alcohol has a chiral center, the product isolated from the redox reaction is not optically active. Explain.
15.123 Biphenyl consists of two benzene rings connected by a single bond. When Cl atoms substitute for some of the H atoms, polychlorinated biphenyls (PCBs) are formed. There are over 200 different PCBs, but only six with one Cl on each ring. Draw these constitutional isomers.
15.124 Wastewater from a cheese factory has the following composition: $8.0 \mathrm{~g} / \mathrm{L}$ protein $\left(\mathrm{C}_{16} \mathrm{H}_{24} \mathrm{O}_{5} \mathrm{~N}_{4}\right) ; 12 \mathrm{~g} / \mathrm{L}$ carbohydrate $\left(\mathrm{CH}_{2} \mathrm{O}\right)$; and $2.0 \mathrm{~g} / \mathrm{L}$ fat $\left(\mathrm{C}_{8} \mathrm{H}_{16} \mathrm{O}\right)$. What is the total organic carbon (TOC) of the wastewater in g of $\mathrm{C} / \mathrm{L}$ ?

## 16

Rate and Survival Evidence mounts that, unlike modern reptiles, a dinosaur such as the mighty Tyrannosaurus rex could generate enough metabolic heat to sustain its biochemical reactions at high rates. In this chapter, you'll see how reaction rate is influenced by several factors, including temperature, and how chemists can control those factors.

## Kinetics: Rates and Mechanisms of Chemical Reactions

16.1 Factors That Influence Reaction Rate

The Mechanism and the Rate Law
16.8 Catalysis: Speeding Up a Chemical Reaction
Homogeneous Catalysis
Heterogeneous Catalysis

Until now we've taken a rather simple approach to chemical change: reactants mix and products form. A balanced equation is an essential quantitative tool for calculating product yields from reactant amounts, but it tells us nothing about three dynamic aspects of the reaction, which are essential to understanding chemical change and which we examine in the next several chapters:

- How fast is the reaction proceeding at a given moment?
- What will reactant and product concentrations be when the reaction is complete?
- Will the reaction proceed by itself and release energy, or will it require energy to proceed?

This chapter addresses the first of these questions and focuses on the field of kinetics, which deals with the speed of a reaction and its mechanism, the stepwise changes that reactants undergo in their conversion to products. Chapters 17 through 19 are concerned with equilibrium, the dynamic balance between forward and reverse reactions and how external influences alter reactant and product concentrations. Chapters 20 and 21 present thermodynamics and its application to electrochemistry; there, we investigate why reactions occur and how we can put them to use. These central subdisciplines of chemistry apply to all physical and chemical change and, thus, are crucial to our understanding of modern technology, the environment, and the reactions in living things.

Chemical kinetics is the study of reaction rates, the changes in concentrations of reactants (or products) as a function of time (Figure 16.1). Reactant concentrations decrease quickly in a reaction with a high rate and slowly in a reaction with a low rate.

Reactions occur at a wide range of rates (Figure 16.2). Some, like a neutralization, a precipitation, or an explosive redox process, seem to be over as soon as the reactants make contact-in a fraction of a second. Others, such as the reactions involved in cooking or rusting, take a moderate length of time, from minutes to months. Still others take much longer: the reactions that make up the human aging process continue for decades, and those involved in the formation of coal from dead plants take hundreds of millions of years.

## Concepts \& Skills to Review before you study this chapter

- influence of temperature on molecular speed and collision frequency (Section 5.6)

Figure 16.1 Reaction rate: the central focus of chemical kinetics. The rate at which reactant becomes product is the underlying theme of chemical kinetics. As time elapses, reactant (purple) decreases and product (green) increases.

Figure 16.2 The wide range of reaction rates. Reactions proceed at a wide range of rates. An explosion (A) is much faster than the process of ripening (B), which is much faster than the process of rusting (C), which is much faster than the process of human aging (D).

Knowing how fast a chemical change occurs can be essential. How quickly a medicine acts or blood clots can make the difference between life and death. How long it takes for cement to harden or polyethylene to form can make the difference between profit and loss. In general, the rates of these diverse processes depend on the same variables, most of which chemists can manipulate to maximize yields within a given time or to slow down an unwanted reaction.

IN THIS CHAPTER . . . We first overview three key factors that affect reaction rate. Then we see how to express rate in the form of a rate law and how the components of a rate law are determined experimentally. We focus on the effects of concentration and temperature on rate and examine the models that explain those effects. Only then can we develop a reaction mechanism by noting the steps the reaction goes through and picturing the structure that exists as reactant bonds are breaking and product bonds are forming. Finally, we discuss how catalysts increase reaction rates, highlighting two vital areas-the reactions of a living cell and the depletion of atmospheric ozone.

### 16.1 FACTORS THAT INFLUENCE REACTION RATE

Let's begin our study of kinetics with a qualitative look at the key factors that affect how fast a reaction proceeds. Under any given set of conditions, each reaction has its own characteristic rate, which is determined by the chemical nature of the reactants. At room temperature, for example, hydrogen reacts explosively with fluorine but extremely slowly with nitrogen:

$$
\begin{array}{cl}
\mathrm{H}_{2}(g)+\mathrm{F}_{2}(g) \longrightarrow & 2 \mathrm{HF}(g)
\end{array} \begin{aligned}
& {[\text { very fast }]} \\
& 3 \mathrm{H}_{2}(g)+\mathrm{N}_{2}(g) \longrightarrow
\end{aligned} 2 \mathrm{NH}_{3}(g) \quad[\text { very slow }]
$$

We can control four factors that affect the rate of a given reaction: the concentriens of the reatants, the physteafstate of the reactants, the temperature at which the reaction occurs, and the use of a catalyst. We'll consider the first three factors here and discuss the fourth in Section 16.8.

1. Concentration: molecules must collide to react. A major factor influencing the rate of a given reaction is reactant concentration. Consider the reaction between ozone and nitrogen monoxide (nitric oxide) that occurs in the stratosphere, where the oxide is released in the exhaust gases of supersonic aircraft:

$$
\mathrm{NO}(g)+\mathrm{O}_{3}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)
$$

Imagine what this might look like at the molecular level with the reactants confined in a reaction vessel. Nitrogen monoxide and ozone molecules zoom every which way, crashing into each other and the vessel walls. A reaction between NO and $\mathrm{O}_{3}$ can occur only when the molecules collide. The more molecules present in the container, the more frequently they collide, and the more often a reaction occurs. Thus, reaction rate is proportional to the concentration of reactants:

$$
\text { Rate } \propto \text { collision frequency } \propto \text { concentration }
$$

In this case, we're looking at a very simple reaction, one in which reactant molecules collide and form product molecules in one step, but even the rates of complex reactions depend on reactant concentration.
2. Physical state: molecules must mix to collide. The frequency of collisions between molecules also depends on the physical states of the reactants. When the reactants are in the same phase, as in an aqueous solution, random thermal motion brings them into contact. When they are in different phases, contact occurs only at the interface, so vigorous stirring and grinding may be needed. In these cases, the more finely divided a solid or liquid reactant, the greater its surface area per unit volume, the more contact it makes with the other reactant, and the faster the reaction occurs. Figure 16.3 A shows a steel nail heated in oxygen glowing feebly; in Figure 16.3B, the same mass of steel wool bursts into flame. For the same reason, you start a campfire with wood chips and thin branches, not logs.
3. Temperature: molecules must collide with enough energy to react. Temperature usually has a major effect on the speed of a reaction. Two familiar kitchen appliances employ this effect: a refrigerator slows down chemical processes that spoil food, whereas an oven speeds up other chemical processes that cook it.

Recall that molecules in a sample of gas have a range of speeds, with the most probable speed dependent on the temperature (see Figure 5.14, p. 211). Thus, at a higher temperature, more collisions occur in a given time. Even more important, however, is the fact that temperature affects the kinetic energy of the molecules, and thus the energy of the collisions. In the jumble of molecules in the reaction of NO and $\mathrm{O}_{3}$, mentioned previously, most collisions result in the molecules simply recoiling, like billiard balls, with no reaction taking place. However, some collisions occur with sufficient energy for the molecules to react (Figure 16.4). And, at a higher temperature, more of these sufficiently energetic collisions occur. Thus, raising the temperature increases the reaction rate by increasing the number and, especially, the energy of the collisions:

## Rate $\propto$ collision energy $\propto$ temperature

The qualitative idea that reaction rate is influenced by the frequency and energy of reactant collisions leads to several quantitative questions: How can we describe the dependence of rate on reactant concentration mathematically? Do all changes in concentration affect the rate to the same extent? Do all rates increase to the same extent with a given rise in temperature? How do reactant molecules use the energy of collision to form product molecules, and is there a way to determine this energy? What do the reactants look like as they are turning into products? We address these questions in the following sections.

## Section Summary

Chemical kinetics deals with reaction rates and the stepwise molecular events by which a reaction occurs. - Under a given set of conditions, each reaction has its own rate. - Concentration affects rate by influencing the frequency of collisions between reactant molecules. Physical state affects rate by determining the surface area per unit volume of reactant(s). Temperature affects rate by influencing the frequency and, even more importantly, the energy of the reactant collisions.

### 16.2 EXPRESSING THE REACTION RATE

Before we can deal quantitatively with the effects of concentration and temperature on reaction rate, we must express the rate mathematically. A rate is a change in some variable per unit of time. The most common examples relate to the rate of motion (speed) of an object, which is the change in its position divided by the change in time. Suppose, for instance, we measure a runner's starting position, $x_{1}$, at time $t_{1}$ and final position, $x_{2}$, at time $t_{2}$. The runner's average speed is

$$
\text { Rate of motion }(\text { speed })=\frac{\text { change in position }}{\text { change in time }}=\frac{x_{2}-x_{1}}{t_{2}-t_{1}}=\frac{\Delta x}{\Delta t}
$$

In the case of a chemical change, we are concerned with the reaction rate, the changes in concentrations of reactants or products per unit time: reactant concentrations decrease while product concentrations increase. Consider a general reaction, $\mathrm{A} \longrightarrow \mathrm{B}$. We quickly measure the starting reactant concentration (conc $\mathrm{A}_{1}$ ) at $t_{1}$, allow the reaction to proceed, and then quickly measure the reactant concentration again (conc $\mathrm{A}_{2}$ ) at $t_{2}$. The change in concentration divided by the change in time gives the average rate:
Rate of reaction $=-\frac{\text { change in concentration of } \mathrm{A}}{\text { change in time }}=-\frac{\operatorname{conc} \mathrm{A}_{2}-\operatorname{conc} \mathrm{A}_{1}}{t_{2}-t_{1}}=-\frac{\Delta(\operatorname{conc} \mathrm{A})}{\Delta t}$

Figure 16.4 Collision energy and reaction rate. The reaction equation is shown in the panel. Although many collisions between NO and $\mathrm{O}_{3}$ molecules occur, relatively few have enough energy to cause reaction. At this temperature, only collision a is energetic enough to lead to product; the reactant molecules in collisions $b$ and $c$ just bounce off each other.

Runners changing position with time.

Note the minus sign. By convention, reaction rate is a positive number, but conc $\mathrm{A}_{2}$ will always be lower than conc $\mathrm{A}_{1}$, so the change in concentration (final initial) of reactant $A$ is always negative. We use the minus sign simply to convert the negative change in reactant concentration to a positive value for the rate. Suppose the concentration of A changes from $1.2 \mathrm{~mol} / \mathrm{L}$ (conc $\mathrm{A}_{1}$ ) to $0.75 \mathrm{~mol} / \mathrm{L}$ (conc $\mathrm{A}_{2}$ ) over a 125 -s period. The average rate is

$$
\text { Rate }=-\frac{0.75 \mathrm{~mol} / \mathrm{L}-1.2 \mathrm{~mol} / \mathrm{L}}{125 \mathrm{~s}-0 \mathrm{~s}}=3.6 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}
$$

We use square brackets, [ ], to express concentration in moles per liter. That is, [A] is the concentration of A in $\mathrm{mol} / \mathrm{L}$, so the rate expressed in terms of A is

$$
\begin{equation*}
\text { Rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t} \tag{16.1}
\end{equation*}
$$

The rate has units of moles per liter per second ( $\mathrm{mol} \mathrm{L}^{-1} \mathrm{~s}^{-1}$, or $\mathrm{mol} / \mathrm{L} \cdot \mathrm{s}$ ), or any time unit convenient for the particular reaction (minutes, years, and so on).

If instead we measure the product to determine the reaction rate, we find its concentration increasing over time. That is, conc $\mathrm{B}_{2}$ is always higher than conc $B_{1}$. Thus, the change in product concentration, $\Delta[B]$, is positive, and the reaction rate for $A \longrightarrow B$ expressed in terms of $B$ is

$$
\text { Rate }=\frac{\Delta[\mathrm{B}]}{\Delta t}
$$

## Average, Instantaneous, and Initial Reaction Rates

In most reactions, not only the concentration changes, but the rate itself varies with time as the reaction proceeds. Consider the reversible gas-phase reaction
 formation of photochemical smog:

$$
\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})+\mathrm{O}_{3}(\mathrm{~g}) \rightleftharpoons \mathrm{C}_{2} \mathrm{H}_{4} \mathrm{O}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})
$$

For now, we consider only reactant concentrations. You can see from the equation coefficients that for every molecule of $\mathrm{C}_{2} \mathrm{H}_{4}$ that reacts, a molecule of $\mathrm{O}_{3}$ reacts with it. In other words, the concentrations of both reactants decrease at the same rate in this particular reaction:

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{C}_{2} \mathrm{H}_{4}\right]}{\Delta t}=-\frac{\Delta\left[\mathrm{O}_{3}\right]}{\Delta t}
$$

By measuring the concentration of either reactant, we can follow the reaction rate.
Suppose we have a known concentration of $\mathrm{O}_{3}$ in a closed reaction vessel kept at $30^{\circ} \mathrm{C}(303 \mathrm{~K})$. Table 16.1 shows the concentration of $\mathrm{O}_{3}$ at various times during the first minute after we introduce $\mathrm{C}_{2} \mathrm{H}_{4}$ gas. The rate over the entire 60.0 s is the total change in concentration divided by the change in time:

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{O}_{3}\right]}{\Delta t}=-\frac{\left(1.10 \times 10^{-5} \mathrm{~mol} / \mathrm{L}\right)-\left(3.20 \times 10^{-5} \mathrm{~mol} / \mathrm{L}\right)}{60.0 \mathrm{~s}-0.0 \mathrm{~s}}=3.50 \times 10^{-7} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}
$$

This calculation gives us the average rate over that period; that is, during the first 60.0 s of the reaction, ozone concentration decreases an average of $3.50 \times 10^{-7} \mathrm{~mol} / \mathrm{L}$ each second. However, the average rate does not show that the rate is changing, and it tells us nothing about how fast the ozone concentration is decreasing at any given instant.

We can see the rate change during the reaction by calculating the average rate over two shorter periods-one earlier and one later. Between the starting time 0.0 s and 10.0 s , the average rate is

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{O}_{3}\right]}{\Delta t}=-\frac{\left(2.42 \times 10^{-5} \mathrm{~mol} / \mathrm{L}\right)-\left(3.20 \times 10^{-5} \mathrm{~mol} / \mathrm{L}\right)}{10.0 \mathrm{~s}-0.0 \mathrm{~s}}=7.80 \times 10^{-7} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}
$$

During the last 10.0 s , between 50.0 s and 60.0 s , the average rate is
Rate $=-\frac{\Delta\left[\mathrm{O}_{3}\right]}{\Delta t}=-\frac{\left(1.10 \times 10^{-5} \mathrm{~mol} / \mathrm{L}\right)-\left(1.23 \times 10^{-5} \mathrm{~mol} / \mathrm{L}\right)}{60.0 \mathrm{~s}-50.0 \mathrm{~s}}=1.30 \times 10^{-7} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$
The earlier rate is six times as fast as the later rate. Thus, the rate decreases during the course of the reaction. This makes perfect sense from a molecular point of view: as $\mathrm{O}_{3}$ molecules are used up, fewer of them are present to collide with $\mathrm{C}_{2} \mathrm{H}_{4}$ molecules, so the rate, the change in their concentration over time, decreases.

The change in rate can also be seen by plotting the concentrations vs. the times at which they were measured (Figure 16.5). A curve is obtained, which means that the rate changes. The slope of the straight line $(\Delta y / \Delta x$, that is, $\Delta\left[\mathrm{O}_{3}\right] / \Delta t$ ) joining any two points gives the average rate over that period.

The shorter the time period we choose, the closer we come to the instantaneous rate, the rate at a particular instant during the reaction. The slope of a line tangent to the curve at a particular point gives the instantaneous rate at that time. For example, the rate of the reaction of $\mathrm{C}_{2} \mathrm{H}_{4}$ and $\mathrm{O}_{3} 35.0 \mathrm{~s}$ after it began is $2.50 \times 10^{-7} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$, the slope of the line drawn tangent to the curve through the point at which $t=35.0 \mathrm{~s}$ (line $d$ in Figure 16.5). In general, we use the term reaction rate to mean the instantaneous reaction rate.

As a reaction continues, the product concentrations increase, and so the reverse reaction (reactants $\longleftarrow$ products) proceeds more quickly. To find the overall (net) rate, we would have to take both forward and reverse reactions into account and calculate the difference between their rates. A common way to avoid this complication for many reactions is to measure the initial rate, the instantaneous rate at the moment the reactants are mixed. Under these conditions, the product concentrations are negligible, so the reverse rate is negligible. Moreover, we know the reactant concentrations from the concentrations and volumes of the solutions we mix together. The inithatitedrasured by determining the slope of the line tangent to the curve at $t=0 \mathrm{~s}$. In Figure 16.5, the initial rate is $10.0 \times 10^{-7} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$ (line $a$ ). Unless stated otherwise, we will use initial rate data to determine other kinetic parameters.

Figure 16.5 The concentration of $\mathrm{O}_{3}$ vs. time during its reaction with $\mathrm{C}_{2} \mathrm{H}_{4}$. Plotting the data in Table 16.1 gives a curve because the rate changes during the reaction. The average rate over a given period is the slope of a line joining two points along the curve. The slope of line $b$ is the average rate over the first 60.0 s of the reaction. The slopes of lines $c$ and $e$ give the average rate over the first and last 10.0-s intervals, respectively. Line $c$ is steeper than line $e$ because the average rate over the earlier period is higher. The instantaneous rate at 35.0 s is the slope of line $d$, the tangent to the curve at $t=35.0 \mathrm{~s}$. The initial rate is the slope of line $a$, the tangent to the curve at $t=0 \mathrm{~s}$.

Figure 16.6 Plots of $\left[\mathrm{C}_{2} \mathrm{H}_{4}\right]$ and $\left[\mathrm{O}_{2}\right]$ vs. time. Measuring reactant concentration, $\left[\mathrm{C}_{2} \mathrm{H}_{4}\right]$, and product concentration, $\left[\mathrm{O}_{2}\right]$, gives curves of identical shapes but changing in opposite directions. The steep upward (positive) slope of $\left[\mathrm{O}_{2}\right]$ early in the reaction mirrors the steep downward (negative) slope of $\left[\mathrm{C}_{2} \mathrm{H}_{4}\right]$ because the faster $\mathrm{C}_{2} \mathrm{H}_{4}$ is used up, the faster $\mathrm{O}_{2}$ is formed.

## Expressing Rate in Terms of Reactant and Product Concentrations

So far, in our discussion of the reaction of $\mathrm{C}_{2} \mathrm{H}_{4}$ and $\mathrm{O}_{3}$, we've expressed the rate in terms of the decreasing concentration of $\mathrm{O}_{3}$. The rate is the same in terms of $\mathrm{C}_{2} \mathrm{H}_{4}$, but it is exactly the opposite in terms of the products because their concentrations are increasing. From the balanced equation, we see that one molecule of $\mathrm{C}_{2} \mathrm{H}_{4} \mathrm{O}$ and one of $\mathrm{O}_{2}$ appear for every molecule of $\mathrm{C}_{2} \mathrm{H}_{4}$ and of $\mathrm{O}_{3}$ that disappear. We can express the rate in terms of any of the four substances involved:

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{C}_{2} \mathrm{H}_{4}\right]}{\Delta t}=-\frac{\Delta\left[\mathrm{O}_{3}\right]}{\Delta t}=+\frac{\Delta\left[\mathrm{C}_{2} \mathrm{H}_{4} \mathrm{O}\right]}{\Delta t}=+\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}
$$

Again, note the negative values for the reactants and the positive values for the products (usually written without the plus sign). Figure 16.6 shows a plot of the simultaneous monitoring of one reactant and one product. Because, in this case, product concentration increases at the same rate that reactant concentration decreases, the curves have the same shapes but are inverted.

In many other cases, though, the reactants disappear and the products appear at different rates. Consider the reaction between hydrogen and iodine to form hydrogen iodide:

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \longrightarrow 2 \mathrm{HI}(g)
$$

For every molecule of $\mathrm{H}_{2}$ that disappears, one molecule of $\mathrm{I}_{2}$ disappears and two molecules of HI appear. In other words, the rate of $\left[\mathrm{H}_{2}\right]$ decrease is the same as the rate of $\left[\mathrm{I}_{2}\right.$ ] decrease, but both are only half the rate of $[\mathrm{HI}]$ increase. By referring the change in $\left[\mathrm{I}_{2}\right]$ and $[\mathrm{HI}]$ to the change in $\left[\mathrm{H}_{2}\right]$, we have

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{H}_{2}\right]}{\Delta t}=-\frac{\Delta\left[\mathrm{I}_{2}\right]}{\Delta t}=\frac{1}{2} \frac{\Delta[\mathrm{HI}]}{\Delta t}
$$

If we refer the change in $\left[\mathrm{H}_{2}\right]$ and $\left[\mathrm{I}_{2}\right]$ to the change in $[\mathrm{HI}]$ instead, we obtain

Notice that this expression is just a rearrangement of the previous one; also note that it gives a numerical value for the rate that is double the previous value. Thus, the mathematical expression for the rate of a particular reaction and the numerical value of the rate depend on which substance serves as the reference.

We can summarize these results for any reaction,

$$
a \mathrm{~A}+b \mathrm{~B} \longrightarrow c \mathrm{C}+d \mathrm{D}
$$

where $a, b, c$, and $d$ are coefficients of the balanced equation. In general, the rate is related to reactant or product concentrations as follows:

$$
\begin{equation*}
\text { Rate }=-\frac{1}{a} \frac{\Delta[\mathrm{~A}]}{\Delta t}=-\frac{1}{b} \frac{\Delta[\mathrm{~B}]}{\Delta t}=\frac{1}{c} \frac{\Delta[\mathrm{C}]}{\Delta t}=\frac{1}{d} \frac{\Delta[\mathrm{D}]}{\Delta t} \tag{16.2}
\end{equation*}
$$

SAMPLE PROBLEM 16.1 Expressing Rate in Terms of Changes in Concentration with Time
PROBLEM Because it has a nonpolluting combustion product (water vapor), hydrogen gas is used for fuel aboard the space shuttles and in earthbound cars with prototype engines:

$$
2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(g)
$$

(a) Express the rate in terms of changes in $\left[\mathrm{H}_{2}\right],\left[\mathrm{O}_{2}\right]$, and $\left[\mathrm{H}_{2} \mathrm{O}\right]$ with time.
(b) When $\left[\mathrm{O}_{2}\right]$ is decreasing at $0.23 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$, at what rate is $\left[\mathrm{H}_{2} \mathrm{O}\right]$ increasing?

PLAN (a) Of the three substances in the equation, let's choose $\mathrm{O}_{2}$ as the reference because its coefficient is 1 . For every molecule of $\mathrm{O}_{2}$ that disappears, two molecules of $\mathrm{H}_{2}$ disappear, so the rate of $\left[\mathrm{O}_{2}\right]$ decrease is one-half the rate of $\left[\mathrm{H}_{2}\right]$ decrease. By similar reasoning, we see that the rate of $\left[\mathrm{O}_{2}\right]$ decrease is one-half the rate of $\left[\mathrm{H}_{2} \mathrm{O}\right]$ increase. (b) Because $\left[\mathrm{O}_{2}\right]$ is decreasing, the change in its concentration must be negative. We substitute the negative value into the expression and solve for $\Delta\left[\mathrm{H}_{2} \mathrm{O}\right] / \Delta t$.

SOLUTION (a) Expressing the rate in terms of each component:

$$
\text { Rate }=-\frac{1}{2} \frac{\Delta\left[\mathrm{H}_{2}\right]}{\Delta t}=-\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}=\frac{1}{2} \frac{\Delta\left[\mathrm{H}_{2} \mathrm{O}\right]}{\Delta t}
$$

(b) Calculating the rate of change of $\left[\mathrm{H}_{2} \mathrm{O}\right]$ :

$$
\begin{aligned}
\frac{1}{2} \frac{\Delta\left[\mathrm{H}_{2} \mathrm{O}\right]}{\Delta t} & =-\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}=-(-0.23 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}) \\
\frac{\Delta\left[\mathrm{H}_{2} \mathrm{O}\right]}{\Delta t} & =2(0.23 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s})=0.46 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}
\end{aligned}
$$

CHECK (a) A good check is to use the rate expression to obtain the balanced equation: [ $\mathrm{H}_{2}$ ] changes twice as fast as [ $\left.\mathrm{O}_{2}\right]$, so two $\mathrm{H}_{2}$ molecules react for each $\mathrm{O}_{2}$. $\left[\mathrm{H}_{2} \mathrm{O}\right]$ changes twice as fast as $\left[\mathrm{O}_{2}\right]$, so two $\mathrm{H}_{2} \mathrm{O}$ molecules form from each $\mathrm{O}_{2}$. From this reasoning, we get $2 \mathrm{H}_{2}+\mathrm{O}_{2} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}$. The $\left[\mathrm{H}_{2}\right]$ and $\left[\mathrm{O}_{2}\right]$ decrease, so they take minus signs; [ $\mathrm{H}_{2} \mathrm{O}$ ] increases, so it takes a plus sign. Another check is to use Equation 16.2, with $\mathrm{A}=\mathrm{H}_{2}$, $a=2 ; \mathrm{B}=\mathrm{O}_{2}, b=1 ; \mathrm{C}=\mathrm{H}_{2} \mathrm{O}, c=2$. Thus,
or

$$
\begin{aligned}
& \text { Rate }=-\frac{1}{a} \frac{\Delta[\mathrm{~A}]}{\Delta t}=-\frac{1}{b} \frac{\Delta[\mathrm{~B}]}{\Delta t}=\frac{1}{c} \frac{\Delta[\mathrm{C}]}{\Delta t} \\
& \text { Rate }=-\frac{1}{2} \frac{\Delta\left[\mathrm{H}_{2}\right]}{\Delta t}=-\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}=\frac{1}{2} \frac{\Delta\left[\mathrm{H}_{2} \mathrm{O}\right]}{\Delta t}
\end{aligned}
$$

(b) Given the rate expression, it makes sense that the numerical value of the rate of $\left[\mathrm{H}_{2} \mathrm{O}\right]$ increase is twice that of $\left[\mathrm{O}_{2}\right]$ decrease.
COMMENT Thinking through this type of problem at the molecular level is the best approach, but use Equation 16.2 to confirm your answer.
FOLLOW-UP PROBLEM 16.1 (a) Balance the following equation and express the rate in terms of the change in concentration with time for each substance:

$$
\mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{N}_{2} \mathrm{O}_{3}(g)
$$

(b) How fast is $\left[\mathrm{O}_{2}\right]$ decreasing when $[\mathrm{NO}]$ is decreasing at a rate of $1.60 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$ ?

## Section Summary

The average reaction rate is the change in reactant (or product) concentration over a change in time, $\Delta t$. The rate slows as reactants are used up. The instantaneous rate at time $t$ is obtained from the slope of the tangent to a concentration vs. time curve at time $t$. The initial rate, the instantaneous rate at $t=0$, occurs when reactants are just mixed and before any product accumulates. - The expression for a reaction rate and its numerical value depend on which reaction component is being monitored.

### 16.3 THE RATE LAW AND ITS COMPONENTS

The centerpiece of any kinetic study is the rate law (or rate equation) for the reaction in question. The rate law expresses the rate as a function of reactant concentrations, product concentrations, and temperature. Any hypothesis we make about how the reaction occurs on the molecular level must conform to the rate law because it is based on experimental fact.

In this discussion, we generally consider reactions for which the products do not appear in the rate law. In these cases, the reaction rate depends only on reactant concentrations and temperature. First, we look at the effect of concentration on rate for reactions occurring at a fixed temperature. For a general reaction,

$$
a \mathrm{~A}+b \mathrm{~B}+\cdots \longrightarrow c \mathrm{C}+d \mathrm{D}+\cdots
$$

the rate law has the form

$$
\begin{equation*}
\text { Rate }=k[\mathrm{~A}]^{m}[\mathrm{~B}]^{n} \ldots \tag{16.3}
\end{equation*}
$$

Aside from the concentration terms, $[\mathrm{A}]$ and $[\mathrm{B}]$, the other parameters in Equation 16.3 require some definition. The proportionality constant $k$, called the rate constant, is specific for a given reaction at a given temperature; it does not change as the reaction proceeds. (As you'll see in Section 16.5, $k$ does change with temperature and therefore determines how temperature affects the rate.) The exponents $m$ and $n$, called the reaction orders, define how the rate is affected by reactant concentration. Thus, if the rate doubles when [A] doubles, the rate depends on $[\mathrm{A}]$ raised to the first power, $[\mathrm{A}]^{1}$, so $m=1$. Similarly, if the rate quadruples when $[\mathrm{B}]$ doubles, the rate depends on $[\mathrm{B}]$ raised to the second power, $[B]^{2}$, so $n=2$. In another reaction, the rate may not change at all when $[A]$ doubles; in that case, the rate does not depend on [A] or, to put it another way, the rate depends on $[\mathrm{A}]$ raised to the zero power, $[\mathrm{A}]^{0}$, so $m=0$. Keep in mind that the coefficients $a$ and $b$ in the general balanced equation are not necessarily related in any way to the reaction orders $m$ and $n$.

A key point to remember is that the components of the rate law-rate, reaction orders, and rate constant-must be found by experiment; they cannot be

## Tools of the Laboratory

## Measuring Reaction Rates

Speculation about how a reaction occurs at the molecular level must be based on measurements of reaction rates. There are many experimental approaches, but all must obtain the results quickly and reproducibly. We consider four common methods, with specific examples.

## Spectrometric Methods

These methods are used to measure the concentration of a reactant or product that absorbs (or emits) light of a narrow range of wavelengths. The reaction is typically performed within the sample compartment of a spectrometer that has been set to measure a wavelength characteristic of one of the species (Figure B16.1; see also Tools of the Laboratory, pp. 281-282). For example, in the reaction of NO and $\mathrm{O}_{3}$, only $\mathrm{NO}_{2}$ has a color:

$$
\begin{aligned}
& \mathrm{NO}(g, \text { colorless })+\mathrm{O}_{3}(g, \text { colorless }) \longrightarrow \\
& \mathrm{O}_{2}(g, \text { colorless })+\mathrm{NO}_{2}(g, \text { brown })
\end{aligned}
$$

Known amounts of the reactants are injected into a gas sample tube of known volume, and the rate of $\mathrm{NO}_{2}$ formation is measured by monitaring the color over time. Reactions in aqueous solution are studied similarly.

## Conductometric Methods

When nonionic reactants form ionic products, or vice versa, the change in conductivity of the solution over time can be used to measure the rate. Electrodes are immersed in the reaction mixture, and the increase (or decrease) in conductivity correlates with the formation of product (Figure B16.2). Consider the reaction between an organic halide, such as 2-bromo-2-methylpropane, and water:

$$
\begin{array}{r}
\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}-\mathrm{Br}(l)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \\
\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}-\mathrm{OH}(l)+\mathrm{H}^{+}(a q)+\mathrm{Br}^{-}(a q)
\end{array}
$$

The HBr that forms is a strong acid in water, so it dissociates completely into ions. As time passes, more ions form, so the conductivity of the reaction mixture increases.

Figure B16.1 Spectrometric monitoring of a reaction. The investigator adds the reactant(s) to the sample tube and immediately places it in the spectrometer. For a reactant (or product) that is colored, rate data are determined from a plot of absorbance (of light of particular wavelength) vs. time. The rate of disappearance of a blue dye is being studied here.
deduced from the reaction stoichiometry. So let's take an experimental approach to finding the components by

1. Using concentration measurements to find the initial rate
2. Using initial rates from several experiments to find the reaction orders
3. Using these values to calculate the rate constant

Once we know the rate law, we can use it to predict the rate for any initial reactant concentrations.

## Determining the Initial Rate

In the last section, we showed how initial rates are determined from a plot of concentration vs. time. Because we use initial rate data to determine the reaction orders and rate constant, an accurate experimental method for measuring concentration at various times during the reaction is essential to finding the rate law. A few of the many techniques used for measuring changes in concentration over time are presented in the Tools of the Laboratory essay, which begins on p. 692.

Figure B16.2 Conductometric monitoring of a reaction. When a reactant mixture differs in conductivity from the product mixture, the change in conductivity is proportional to the reaction rate. This method is usually used when nonionic reactants form ionic products.

## Manometric Methods

If a reaction involves a change in the number of moles of a gaseous reactant or product, the rate can be determined from the change in pressure (at constant volume and temperature) over time. In practice, a manometer is attached to a reaction vessel of known volume that is immersed in a constant-temperature bath. For example, the reaction between zinc and acetic acid can be monitored by this method:

$$
\mathrm{Zn}(s)+2 \mathrm{CH}_{3} \mathrm{COOH}(a q) \xrightarrow{\mathrm{Zn}^{2+}(a q)}+2 \mathrm{CH}_{3} \mathrm{COO}^{-}(a q)+\mathrm{H}_{2}(g)
$$

As $\mathrm{H}_{2}$ forms, the gas pressure increases. Thus, the reaction rate is directly proportional to the rate of increase of the $\mathrm{H}_{2}$ gas pressure. In Figure B16.3, this method is being used to study a reaction involving nitrogen dioxide.

Figure B16.3 Manometric monitoring of a reaction. When a reaction results in a change in the number of moles of gas, the change in pressure with time corresponds to a change in reaction rate. The rate of formation of $\mathrm{NO}_{2}$ from $\mathrm{N}_{2} \mathrm{O}_{4}$ is being studied here.

## Direct Chemical Methods

Rates of slow reactions, or of those that can be easily slowed, are often studied by direct chemical methods. A small, measured portion (called an aliquot) of the reaction mixture is removed, and the reaction in this portion is stopped, usually by rapid cooling. The concentration of reactant or product in the aliquot is measured, while the bulk of the reaction mixture continues to react and is sampled later. For example, the reaction between an organic halide and water can be studied by titration, as well as by conductometric monitoring. The reaction rate in an aliquot is slowed by quickly transferring it to a chilled flask in an ice bath. HBr concentration in the aliquot is determined by titrating with standardized NaOH solution. To determine the change in HBr concentration with time, the procedure is repeated at regular intervals during the reaction.

## Reaction Order Terminology

Before we see how reaction orders are determined from initial rate data, let's discuss the meaning of reaction order and some important terminology. We speak of a reaction as having an individual order "with respect to" or "in" each reactant as well as an overall order, which is simply the sum of the individual orders.

In the simplest case, a reaction with a single reactant A , the reaction is first order overall if the rate is directly proportional to [A]:

$$
\text { Rate }=k[\mathrm{~A}]
$$

It is second order overall if the rate is directly proportional to the square of [A]:

$$
\text { Rate }=k[\mathrm{~A}]^{2}
$$

And it is zero order overall if the rate is not dependent on $[\mathrm{A}]$ at all, a situation that is quite common in metal-catalyzed and biochemical processes:

$$
\text { Rate }=k[\mathrm{~A}]^{0}=k(1)=k
$$

Here are some real examples. For the reaction between nitrogen monoxide and ozone,

$$
\mathrm{NO}(g)+\mathrm{O}_{3}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)
$$

the rate law has been experimentally determined to be

$$
\text { Rate }=k[\mathrm{NO}]\left[\mathrm{O}_{3}\right]
$$

This reaction is first order with respect to NO (or first order in NO), which means that the rate depends on NO concentration raised to the first power, that is, $[\mathrm{NO}]^{1}$ (an exponent of 1 is generally omitted). It is also first order with respect to $\mathrm{O}_{3}$, or $\left[\mathrm{O}_{3}\right]^{1}$. This reaction is second order overall $(1+1=2)$.

The rate law for this reaction has been determined to be

$$
\text { Rate }=k\left[\mathrm{NO}^{2}\left[\mathrm{H}_{2}\right]\right.
$$

The reaction is second order in NO and first order in $\mathrm{H}_{2}$, so it is third order overall.
Finally, for the hydrolysis of 2-bromo-2-methylpropane, which we just considered in the Tools of the Laboratory essay,

$$
\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}-\mathrm{Br}(l)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}-\mathrm{OH}(l)+\mathrm{H}^{+}(a q)+\mathrm{Br}^{-}(a q)
$$

the rate law has been found to be

$$
\text { Rate }=k\left[\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr}\right]
$$

This reaction is first order in 2-bromo-2-methylpropane. Note that the concentration of $\mathrm{H}_{2} \mathrm{O}$ does not even appear in the rate law. Thus, the reaction is zero order with respect to $\mathrm{H}_{2} \mathrm{O}\left(\left[\mathrm{H}_{2} \mathrm{O}\right]^{\circ}\right)$. This means that the rate does not depend on the concentration of $\mathrm{H}_{2} \mathrm{O}$. We can also write the rate law as

$$
\text { Rate }=k\left[\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr}\right]\left[\mathrm{H}_{2} \mathrm{O}\right]^{0}
$$

Overall, this is a first-order reaction.
These examples demonstrate a major point: reaction orders cannot be deduced from the balanced equation. For the reaction between NO and $\mathrm{H}_{2}$ and for the hydrolysis of 2-bromo-2-methylpropane, the reaction orders in the rate laws do not correspond to the coefficients of the balanced equations. Reaction orders must be determined from rate data.

Reaction orders are usually positive integers or zero, but they can also be fractional or negative. For the reaction

$$
\mathrm{CHCl}_{3}(g)+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{CCl}_{4}(g)+\mathrm{HCl}(g)
$$

a fractional order appears in the rate law:

$$
\text { Rate }=k\left[\mathrm{CHCl}_{3}\right]\left[\mathrm{Cl}_{2}\right]^{1 / 2}
$$

This reaction order means that the rate depends on the square root of the $\mathrm{Cl}_{2}$ concentration. For example, if the initial $\mathrm{Cl}_{2}$ concentration is increased by a factor of 4 , while the initial $\mathrm{CHCl}_{3}$ concentration is kept the same, the rate increases by a factor of 2 , the square root of the change in $\left[\mathrm{Cl}_{2}\right]$. A negative exponent means that the rate decreases when the concentration of that component increases. Negative orders are often seen for reactions whose rate laws include products. For example, for the atmospheric reaction

$$
2 \mathrm{O}_{3}(\mathrm{~g}) \rightleftharpoons 3 \mathrm{O}_{2}(\mathrm{~g})
$$

the rate law has been shown to be

$$
\text { Rate }=k\left[\mathrm{O}_{3}\right]^{2}\left[\mathrm{O}_{2}\right]^{-1}=k \frac{\left[\mathrm{O}_{3}\right]^{2}}{\left[\mathrm{O}_{2}\right]}
$$

If the $\mathrm{O}_{2}$ concentration doubles, the reaction proceeds half as fast.

SAMPLE PROBLEM 16.2 Determining Reaction Order from Rate Laws
PROBLEM For each of the following reactions, use the given rate law to determine the reaction order with respect to each reactant and the overall order:
(a) $2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)$; rate $=k[\mathrm{NO}]^{2}\left[\mathrm{O}_{2}\right]$
(b) $\mathrm{CH}_{3} \mathrm{CHO}(g) \longrightarrow \mathrm{CH}_{4}(g)+\mathrm{CO}(g)$; rate $=k\left[\mathrm{CH}_{3} \mathrm{CHO}\right]^{3 / 2}$
(c) $\mathrm{H}_{2} \mathrm{O}_{2}(a q)+3 \mathrm{I}^{-}(a q)+2 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{I}_{3}^{-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)$; rate $=k\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]\left[\mathrm{I}^{-}\right]$

PLAN We inspect the exponents in the rate law, not the coefficients of the balanced equation, to find the individual orders, and then take their sum to find the overall reaction order. SOLUTION (a) The exponent of [NO] is 2, so the reaction is second order with respect to
NO, first order with respect to $\mathrm{O}_{2}$, and third order overall.
(b) The reaction is $\frac{3}{2}$ order in $\mathrm{CH}_{3} \mathrm{CHO}$ and $\frac{3}{2}$ order overall.
(c) The reaction is first order in $\mathrm{H}_{2} \mathrm{O}_{2}$, first order in $\mathrm{I}^{-}$, and second order overall.

The reactant $\mathrm{H}^{+}$does not appear in the rate law, so the reaction is zero order in $\mathrm{H}^{+}$. CHECK Be sure that each reactant has an order and that the sum of the individual orders gives the overall order.
FOLLOW-UP PROBLEM 16.2 Experiment shows that the reaction

$$
5 \mathrm{Br}^{-}(a q)+\mathrm{BrO}_{3}^{-}(a q)+6 \mathrm{H}^{+}(a q) \longrightarrow 3 \mathrm{Br}_{2}(l)+3 \mathrm{H}_{2} \mathrm{O}(l)
$$

obeys this rate law: rate $=k\left[\mathrm{Br}^{-}\right]\left[\mathrm{BrO}_{3}^{-}\right]\left[\mathrm{H}^{+}\right]^{2}$. What are the reaction orders in each reactant and the overall reaction order?

## Determining Reaction Orders Experimentally

Sample Problem 16.2 shows how to find the reaction orders from a known rate law. Now let's see how they are found from data before the rate law is known. Consider the reaction between oxygen and nitrogen monoxide, a key step in the formation of acid rain and in the industrial production of nitric acid:

$$
\mathrm{O}_{2}(g)+2 \mathrm{NO}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

The rate law, expressed in general form, is

$$
\text { Rate }=k\left[\mathrm{O}_{2}\right]^{m}[\mathrm{NO}]^{n}
$$

To find the reaction orders, we run a series of experiments, starting each one with a different set of reactant concentrations and obtaining an initial rate in each case.

## Table 16.2 Initial Rates for a Series of Experiments with the Reaction Between $\mathrm{O}_{2}$ and NO

|  | Initial Reactant <br> Concentrations (mol/L) |  |  |
| :---: | :---: | :---: | :---: |
| Experiment | $\mathbf{O}_{\mathbf{2}}$ | NO | Initial Rate <br> $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ |
| 1 | $1.10 \times 10^{-2}$ | $1.30 \times 10^{-2}$ | $3.21 \times 10^{-3}$ |
| 2 | $2.20 \times 10^{-2}$ | $1.30 \times 10^{-2}$ | $6.40 \times 10^{-3}$ |
| 3 | $1.10 \times 10^{-2}$ | $2.60 \times 10^{-2}$ | $12.8 \times 10^{-3}$ |
| 4 | $3.30 \times 10^{-2}$ | $1.30 \times 10^{-2}$ | $9.60 \times 10^{-3}$ |
| 5 | $1.10 \times 10^{-2}$ | $3.90 \times 10^{-2}$ | $28.8 \times 10^{-3}$ |

Table 16.2 shows experiments that change one reactant concentration while keeping the other constant. If we compare experiments 1 and 2 , we see the effect of doubling $\left[\mathrm{O}_{2}\right]$ on the rate. First, we take the ratio of their rate laws:

$$
\frac{\text { Rate } 2}{\text { Rate } 1}=\frac{k\left[\mathrm{O}_{2}\right]_{2}^{m}[\mathrm{NO}]_{2}^{n}}{k\left[\mathrm{O}_{2}\right]_{1}^{m}[\mathrm{NO}]_{1}^{n}}
$$

where $\left[\mathrm{O}_{2}\right]_{2}$ is the $\mathrm{O}_{2}$ concentration for experiment $2,[\mathrm{NO}]_{1}$ is the NO concentration for experiment 1 , and so forth. Because $k$ is a constant and [NO] does not change between these two experiments, these quantities cancel:

$$
\frac{\text { Rate } 2}{\text { Rate } 1}=\frac{\left[\mathrm{O}_{2}\right]_{2}^{m}}{\left[\mathrm{O}_{2}\right]_{1}^{m}}=\left(\frac{\left[\mathrm{O}_{2}\right]_{2}}{\left[\mathrm{O}_{2}\right]_{1}}\right)^{m}
$$

Substituting the values from Table 16.2, we obtain

## $\underset{\text { Divterng, we obtain }}{\frac{6.40 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}}{3.210^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}}=\left(\frac{2.20 \times 10^{-2} \mathrm{~mol} / \mathrm{L}}{1.10 \times 10^{-2} \mathrm{~mol} / \mathrm{L}}\right)^{m}}$

$$
1.99=(2.00)^{m}
$$

Rounding to one significant figure gives

$$
2=2^{m}
$$

therefore,

$$
m=1
$$

The reaction is first order in $\mathrm{O}_{2}$ : when $\left[\mathrm{O}_{2}\right]$ doubles, the rate doubles.
When the exponent is not easy to determine by inspection, you can solve for $m$ as follows: $a=b^{x}$, so $x=\log a / \log b$. Thus, we have $m=\log 1.99 / \log 2.00=$ 0.993 , which rounds to 1 .

To find the order with respect to NO, we compare experiments 3 and 1 , in which $\left[\mathrm{O}_{2}\right]$ is held constant and $[\mathrm{NO}]$ is doubled:

$$
\frac{\text { Rate } 3}{\text { Rate } 1}=\frac{k\left[\mathrm{O}_{2}\right]_{3}^{m}[\mathrm{NO}]_{3}^{n}}{k\left[\mathrm{O}_{2}\right]_{1}^{m}[\mathrm{NO}]_{1}^{n}}
$$

As before, $k$ is constant, and in this pair of experiments [ $\mathrm{O}_{2}$ ] does not change, so these quantities cancel:

$$
\frac{\text { Rate } 3}{\text { Rate } 1}=\left(\frac{[\mathrm{NO}]_{3}}{[\mathrm{NO}]_{1}}\right)^{n}
$$

The actual values give

$$
\frac{12.8 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}{3.21 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}=\left(\frac{2.60 \times 10^{-2} \mathrm{~mol} / \mathrm{L}}{1.30 \times 10^{-2} \mathrm{~mol} / \mathrm{L}}\right)^{n}
$$

Dividing, we obtain

$$
3.99=(2.00)^{n}
$$

Solving for $n$ :
therefore,

$$
\begin{aligned}
& n=\log 3.99 / \log 2.00=2.00 \\
& n=2
\end{aligned}
$$

The reaction is second order in NO : when [ NO ] doubles, the rate quadruples. Thus, the rate law is

$$
\text { Rate }=k\left[\mathrm{O}_{2}\right][\mathrm{NO}]^{2}
$$

You may want to use experiment 1 in combination with experiments 4 and 5 to check this result.

## SAMPLE PROBLEM 16.3 Determining Reaction Orders from Initial Rate Data

PROBLEM Many gaseous reactions occur in car engines and exhaust systems. One of these is

$$
\mathrm{NO}_{2}(g)+\mathrm{CO}(g) \longrightarrow \mathrm{NO}(g)+\mathrm{CO}_{2}(g) \quad \text { rate }=k\left[\mathrm{NO}_{2}\right]^{m}[\mathrm{CO}]^{n}
$$

Use the following data to determine the individual and overall reaction orders:

| Experiment | Initial Rate $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ | Initial $\left[\mathrm{NO}_{2}\right](\mathrm{mol} / \mathrm{L})$ | Initial [CO] (mol/L) |
| :---: | :---: | :---: | :---: |
| 1 | 0.0050 | 0.10 | 0.10 |
| 2 | 0.080 | 0.40 | 0.10 |
| 3 | 0.0050 | 0.10 | 0.20 |

PLAN We need to solve the general rate law for the reaction orders $m$ and $n$. To solve for each exponent, we proceed as in the text, taking the ratio of the rate laws for two experiments in which only the reactant in question changes.
SOLUTION Calculating $m$ in $\left[\mathrm{NO}_{2}\right]^{m}$ : We take the ratio of the rate laws for experiments 1 and 2 , in which $\left[\mathrm{NO}_{2}\right]$ varies but [ CO ] is constant:

$$
\frac{\text { Rate } 2}{\text { Rate } 1}=\frac{k\left[\mathrm{NO}_{2}\right]_{2}^{m}[\mathrm{CO}]_{2}^{n}}{k\left[\mathrm{NO}_{2}\right]_{1}^{m}[\mathrm{CO}]_{1}^{n}}=\left(\frac{\left[\mathrm{NO}_{2}\right]_{2}}{\left[\mathrm{NO}_{2}\right]_{1}}\right)^{m} \quad \text { or } \quad \frac{0.080 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}{0.0050 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}=\left(\frac{0.40 \mathrm{~mol} / \mathrm{L}}{0.10 \mathrm{~mol} / \mathrm{L}}\right)^{m}
$$

This gives $16=(4.0)^{m}$, so we have $m=\log 16 / \log 4.0=2.0$. The reaction is second order in $\mathrm{NO}_{2}$.
Calculating $n$ in $[\mathrm{CO}]^{n}$ : We take the ratio of the rate laws for experiments 1 and 3 , in which [ CO ] varies but $\left[\mathrm{NO}_{2}\right.$ ] is constant:

$$
\frac{\text { Rate } 3}{\text { Rate } 1}=\frac{k\left[\mathrm{NO}_{2}\right]_{3}^{2}[\mathrm{CO}]_{3}^{n}}{k\left[\mathrm{NO}_{2}\right]_{1}^{2}[\mathrm{CO}]_{1}^{n}}=\left(\frac{[\mathrm{CO}]_{3}}{[\mathrm{CO}]_{1}}\right)^{n} \quad \text { or } \quad \frac{0.0050 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}{0.0050 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}=\left(\frac{0.20 \mathrm{~mol} / \mathrm{L}}{0.10 \mathrm{~mol} / \mathrm{L}}\right)^{n}
$$

We have $1.0=(2.0)^{n}$, so $n=0$. The rate does not change when [CO] varies, so the reaction is zero order in CO.

Therefore, the rate law is

$$
\text { Rate }=k\left[\mathrm{NO}_{2}\right]^{2}[\mathrm{CO}]^{0}=k\left[\mathrm{NO}_{2}\right]^{2}(1)=k\left[\mathrm{NO}_{2}\right]^{2}
$$

The reaction is second order overall.
CHECK A good check is to reason through the orders. If $m=1$, quadrupling [ $\mathrm{NO}_{2}$ ] would quadruple the rate; but the rate more than quadruples, so $m>1$. If $m=2$, quadrupling $\left[\mathrm{NO}_{2}\right]$ would increase the rate by a factor of $16\left(4^{2}\right)$. The ratio of rates is $0.080 / 0.005=$ 16 , so $m=2$. In contrast, increasing [CO] has no effect on the rate, which can happen only if $[\mathrm{CO}]^{n}=1$, so $n=0$.
FOLLOW-UP PROBLEM 16.3 Find the rate law and the overall reaction order for the reaction $\mathrm{H}_{2}+\mathrm{I}_{2} \longrightarrow 2 \mathrm{HI}$ from the following data at $450^{\circ} \mathrm{C}$ :

| Experiment | Initial Rate $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ | Initial $\left[\mathrm{H}_{2}\right](\mathrm{mol} / \mathrm{L})$ | Initial $\left[\mathrm{I}_{2}\right](\mathrm{mol} / \mathrm{L})$ |
| :---: | :---: | :---: | :---: |
| 1 | $1.9 \times 10^{-23}$ | 0.0113 | 0.0011 |
| 2 | $1.1 \times 10^{-22}$ | 0.0220 | 0.0033 |
| 3 | $9.3 \times 10^{-23}$ | 0.0550 | 0.0011 |
| 4 | $1.9 \times 10^{-22}$ | 0.0220 | 0.0056 |

To provide a final overview of this idea, we'll go through one more sample problem, this time using molecular scenes to determine reaction orders.

## SAMPLE PROBLEM 16.4 Determining Reaction Orders from a Series of Molecular Scenes

PROBLEM At a particular temperature, two gases, A (red) and B (blue), react to form products. The following molecular scenes represent four experiments run at the same volume, labeled 1 through 4 with their initial rates (in $\mathrm{mol} / \mathrm{L} \cdot \mathrm{s}$ ):

(a) What is the reaction order with respect to A ? With respect to B ? The overall order?
(b) Write the rate law for the reaction.
(c) Predict the initial rate of experiment 4.

PLAN (a) As in previous situations, we find the individual reaction orders by seeing how a change in each reactant changes the rate. The difference here is that, instead of using concentration data, we count numbers of spheres. As before, if an increase in one reactant has no effect on the rate, the order with respect to that reactant is 0 . Similarly, if the increase causes an increase in the rate by the same factor, the order is 1 . And, if the increase in a reactant causes a square of that increase in the rate, the order is 2 . The sum of the individual orders is the overall order. (b) To write the rate law, we use the orders from part (a) as exponents in the general rate law. (c) Using the results from Expts 1 through 3 and the rate law from part (b), we find the initial rate of Expt 4.
SOLUTION (a) Finding the individual and overall orders: For reactant A (red), from Expts 1 and 2 , the number of A doubles (from 2 to 4 ), while B is constant (at 2), and the rate doubles (from $0.5 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$ to $1.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$ ), so the order with respect to A is 1 . For reactant B (blue), from Expts 1 and 3, the number of B doubles (from 2 to 4), while the number of A is constant (at 2), and the rate quadruples (from $0.5 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$ to $2.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$ ), so the order with respect to $B$ is 2 . The overall order is $1+2=3$.
(b) Writing the rate law: The general rate law is rate $=k[\mathrm{~A}]^{m}[\mathrm{~B}]^{n}$, so we have

$$
\text { Rate }=k[\mathrm{~A}][\mathrm{B}]^{2}
$$

(c) Finding the initial rate of Expt 4: Comparing, for example, Expts 3 and 4, we see that the number of A doubles (from 2 to 4 ). Furthermore, the rate law shows that the reaction is first order in A. Therefore, the initial rate in Expt 4 should be $4.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$.
CHECK A good check is to compare other pairs of experiments. (a) Comparing Expts 2 and 3 shows that the number of B doubles, which causes the rate to quadruple, and A decreases by half, which causes the rate to halve; so the overall rate change should double (from $1.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$ to $2.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$ ), which it does. (c) Comparing Expts 2 and 4 , with A constant, shows that the number of B doubles, so the rate should quadruple, which means the initial rate of Expt 4 would be $4.0 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$, as we found.
FOLLOW-UP PROBLEM 16.4 The scenes below show three experiments at a given temperature involving reactants X (black) and Y (green), with their initial rates (in $\mathrm{mol} / \mathrm{L} \cdot \mathrm{s}$ ):

Expt $1=0.25 \times 10^{-5}$

Expt 2 = ?

Expt $3=1.0 \times 10^{-5}$

If the rate law for the reaction is rate $=k[\mathrm{X}]^{2}$ : (a) What is the initial rate of Expt 2? (b) Draw a scene for Expt 3 that involves a single change of the scene for Expt 1.

## Determining the Rate Constant

With the rate, reactant concentrations, and reaction orders known, the sole remaining unknown in the rate law is the rate constant, $k$. The rate constant is specific for a particular reaction at a particular temperature. The experiments with the reaction of $\mathrm{O}_{2}$ and NO were run at the same temperature, so we can use data from any to solve for $k$. From experiment 1 in Table 16.2 , for instance, we obtain

$$
\begin{aligned}
k & =\frac{\text { rate } 1}{\left[\mathrm{O}_{2}\right]_{1}[\mathrm{NO}]_{1}^{2}}=\frac{3.21 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}{\left(1.10 \times 10^{-2} \mathrm{~mol} / \mathrm{L}\right)\left(1.30 \times 10^{-2} \mathrm{~mol} / \mathrm{L}\right)^{2}} \\
& =\frac{3.21 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}}{1.86 \times 10^{-6} \mathrm{~mol}^{3} / \mathrm{L}^{3}}=1.73 \times 10^{3} \mathrm{~L}^{2} / \mathrm{mol}^{2} \cdot \mathrm{~s}
\end{aligned}
$$

Always check that the values of $k$ for a series are constant within experimental error. To three significant figures, the average value of $k$ for the five experiments in Table 16.2 is $1.72 \times 10^{3} \mathrm{~L}^{2} / \mathrm{mol}^{2} \cdot \mathrm{~s}$.

Note the units for the rate constant. With concentrations in mol/L and the reaction rate in units of $\mathrm{mol} / \mathrm{L} \cdot$ time, the units for $k$ depend on the order of the reaction and, of course, the time unit. The units for $k$ in our example, $\mathrm{L}^{2} / \mathrm{mol}^{2} \cdot \mathrm{~s}$, are required to give a rate with units of $\mathrm{mol} / \mathrm{L} \cdot \mathrm{s}$ :

$$
\frac{\mathrm{mol}}{\mathrm{~L} \cdot \mathrm{~s}}=\frac{\mathrm{L}^{2}}{\mathrm{~mol}^{2} \cdot \mathrm{~s}} \times \frac{\mathrm{mol}}{\mathrm{~L}} \times\left(\frac{\mathrm{mol}}{\mathrm{~L}}\right)^{2}
$$

The rate constant will always have these units for an overall third-order reaction with the time unit in seconds. Table 16.3 shows the units of $k$ for some common overall reaction orders, but you can always determine the units mathematically.

## Section Summary

An experimentally determined rate law shows how the rate of a reaction depends on concentration. If we consider only initial rates, the rate law often takes this form: rate $=k[\mathrm{~A}]^{m}[\mathrm{~B}]^{n} \cdots$. . With an accurate method for obtaining initial rates, reaction orders are determined experimentally by comparing rates for different initial concentrations, that is, by performing several experiments and varying the concentration of one reactant at a time to see its effect on the rate. - With rate, concentrations, and reaction orders known, only the rate constant remains to be calculated.

### 16.4 INTEGRATED RATE LAWS: CONCENTRATION CHANGES OVER TIME

Notice that the rate laws we've developed so far do not include time as a variable. They tell us the rate or concentration at a given instant, allowing us to answer a critical question, "How fast is the reaction proceeding at the moment when $y$ moles per liter of A are reacting with $z$ moles per liter of B?" However, by employing different forms of the rate laws, called integrated rate laws, we can consider the time factor and answer other questions, such as "How long will it take for $x$ moles per liter of A to be used up?" and "What is the concentration of A after $y$ minutes of reaction?"

## Integrated Rate Laws for First-, Second-, and Zero-Order Reactions

Consider a simple first-order reaction, $\mathrm{A} \longrightarrow \mathrm{B}$. (Because first- and second-order reactions are more common, we'll discuss them before zero-order reactions.) As we discussed previously, the rate can be expressed as the change in the concentration of A divided by the change in time:

$$
\text { Rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t}
$$

Table 16.3 Units of the Rate Constant $k$ for Several Overall Reaction Orders

## Overall

| Reaction | Units of $\boldsymbol{k}$ |
| :--- | :--- |
| Order | $(t$ in seconds) |

| 0 | $\mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$ |
| :--- | :--- |
|  | $\left(\mathrm{or} \mathrm{mol} \mathrm{L}^{-1} \mathrm{~s}^{-1}\right)$ |
| 1 | $1 / \mathrm{s}\left(\mathrm{or} \mathrm{s}^{-1}\right)$ |
| 2 | $\mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$ |
|  | $\left(\mathrm{or} \mathrm{L} \mathrm{mol}^{-1} \mathrm{~s}^{-1}\right)$ |
| 3 | $\mathrm{~L}^{2} / \mathrm{mol}^{2} \cdot \mathrm{~s}^{2}$ |
|  | $\left(\mathrm{or} \mathrm{L}^{2} \mathrm{~mol}^{-2} \mathrm{~s}^{-1}\right)$ |

General formula:

$$
\text { Units of } k=\frac{\left(\frac{\mathrm{L}}{\mathrm{~mol}}\right)^{\text {order }-1}}{\text { unit of } t}
$$

It can also be expressed in terms of the rate law:

$$
\text { Rate }=k[\mathrm{~A}]
$$

Setting these different expressions equal to each other gives

$$
-\frac{\Delta[\mathrm{A}]}{\Delta t}=k[\mathrm{~A}]
$$

Through the methods of calculus, this expression is integrated over time to obtain the integrated rate law for a first-order reaction:

$$
\begin{equation*}
\ln \frac{[\mathrm{A}]_{0}}{[\mathrm{~A}]_{t}}=k t \quad(\text { first-order reaction; rate }=k[\mathrm{~A}]) \tag{16.4}
\end{equation*}
$$

where $\ln$ is the natural logarithm, $[\mathrm{A}]_{0}$ is the concentration of A at $t=0$, and $[\mathrm{A}]_{t}$ is the concentration of A at any time $t$ during an experiment. In mathematical terms, $\ln \frac{a}{b}=\ln a-\ln b$, so we have

$$
\ln [\mathrm{A}]_{0}-\ln [\mathrm{A}]_{t}=k t
$$

For a general second-order reaction, the expression including time is quite complex, so let's consider the simple case in which the rate law contains only one reactant. Setting the rate expressions equal to each other gives

$$
\text { Rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t}=k[\mathrm{~A}]^{2}
$$

Integrating over time gives the integrated rate law for a second-order reaction involving one reactant:

$$
\begin{equation*}
\frac{1}{[\mathrm{~A}]_{t}}-\frac{1}{[\mathrm{~A}]_{0}}=k t \quad\left(\text { second-order reaction; rate }=k[\mathrm{~A}]^{2}\right) \tag{16.5}
\end{equation*}
$$

## ABoagrero-oned reactionwe tarecer

$$
\text { Rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t}=k[\mathrm{~A}]^{0}
$$

Integrating over time gives the integrated rate law for a zero-order reaction:

$$
\begin{equation*}
\left.[\mathrm{A}]_{t}-[\mathrm{A}]_{0}=-k t \quad \text { (zero-order reaction; rate }=k[\mathrm{~A}]^{0}=k\right) \tag{16.6}
\end{equation*}
$$

Sample Problem 16.5 shows one way integrated rate laws are applied.

## SAMPLE PROBLEM 16.5 Determining the Reactant Concentration

 at a Given TimePROBLEM At $1000^{\circ} \mathrm{C}$, cyclobutane $\left(\mathrm{C}_{4} \mathrm{H}_{8}\right)$ decomposes in a first-order reaction, with the very high rate constant of $87 \mathrm{~s}^{-1}$, to two molecules of ethylene $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$.
(a) If the initial $\mathrm{C}_{4} \mathrm{H}_{8}$ concentration is 2.00 M , what is the concentration after 0.010 s ?
(b) What fraction of $\mathrm{C}_{4} \mathrm{H}_{8}$ has decomposed in this time?

PLAN (a) We must find the concentration of cyclobutane at time $t,\left[\mathrm{C}_{4} \mathrm{H}_{8}\right]_{t}$. The problem tells us this is a first-order reaction, so we use the integrated first-order rate law:

$$
\ln \frac{\left[\mathrm{C}_{4} \mathrm{H}_{8}\right]_{0}}{\left[\mathrm{C}_{4} \mathrm{H}_{8}\right]_{t}}=k t
$$

We know $k\left(87 \mathrm{~s}^{-1}\right), t(0.010 \mathrm{~s})$, and $\left[\mathrm{C}_{4} \mathrm{H}_{8}\right]_{0}(2.00 \mathrm{M})$, so we can solve for $\left[\mathrm{C}_{4} \mathrm{H}_{8}\right]_{t}$. (b) The fraction decomposed is the concentration that has decomposed divided by the initial concentration:

$$
\text { Fraction decomposed }=\frac{\left[\mathrm{C}_{4} \mathrm{H}_{8}\right]_{0}-\left[\mathrm{C}_{4} \mathrm{H}_{8}\right]_{t}}{\left[\mathrm{C}_{4} \mathrm{H}_{8}\right]_{0}}
$$

SOLUTION (a) Substituting the data into the integrated rate law:

$$
\ln \frac{2.00 \mathrm{~mol} / \mathrm{L}}{\left[\mathrm{C}_{4} \mathrm{H}_{8}\right]_{t}}=\left(87 \mathrm{~s}^{-1}\right)(0.010 \mathrm{~s})=0.87
$$

Taking the antilog of both sides:

$$
\frac{2.00 \mathrm{~mol} / \mathrm{L}}{\left[\mathrm{C}_{4} \mathrm{H}_{8}\right]_{t}}=e^{0.87}=2.4
$$

Solving for $\left[\mathrm{C}_{4} \mathrm{H}_{8}\right]_{t}$ :

$$
\left[\mathrm{C}_{4} \mathrm{H}_{8}\right]_{t}=\frac{2.00 \mathrm{~mol} / \mathrm{L}}{2.4}=0.83 \mathrm{~mol} / \mathrm{L}
$$

(b) Finding the fraction that has decomposed after 0.010 s :

$$
\frac{\left[\mathrm{C}_{4} \mathrm{H}_{8}\right]_{0}-\left[\mathrm{C}_{4} \mathrm{H}_{8}\right]_{t}}{\left[\mathrm{C}_{4} \mathrm{H}_{8}\right]_{0}}=\frac{2.00 \mathrm{~mol} / \mathrm{L}-0.83 \mathrm{~mol} / \mathrm{L}}{2.00 \mathrm{~mol} / \mathrm{L}}=0.58
$$

CHECK The concentration remaining after $0.010 \mathrm{~s}(0.83 \mathrm{~mol} / \mathrm{L})$ is less than the starting concentration ( $2.00 \mathrm{~mol} / \mathrm{L}$ ), which makes sense. Raising $e$ to an exponent slightly less than 1 should give a number (2.4) slightly less than the value of $e$ (2.718). Moreover, the final result makes sense: a high rate constant indicates a fast reaction, so it's not surprising that so much decomposes in such a short time.
COMMENT Integrated rate laws are also used to solve for the time it takes to reach a certain reactant concentration, as in the follow-up problem.
FOLLOW-UP PROBLEM 16.5 At $25^{\circ} \mathrm{C}$, hydrogen iodide breaks down very slowly to hydrogen and iodine: rate $=k[\mathrm{HI}]^{2}$. The rate constant at $25^{\circ} \mathrm{C}$ is $2.4 \times 10^{-21} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$. If 0.0100 mol of $\mathrm{HI}(\mathrm{g})$ is placed in a $1.0-\mathrm{L}$ container, how long will it take for the concentration of HI to reach $0.00900 \mathrm{~mol} / \mathrm{L}(10.0 \%$ reacted)?

## Determining the Reaction Order from the Integrated Rate Law

Suppose you don't know the rate law for a reaction and don't have the initial rate data needed to determine the reaction orders (which we did have in Sample Prob-
 that uses concentration and time data directly.

An integrated rate law can be rearranged into the form of an equation for a straight line, $y=m x+b$, where $m$ is the slope and $b$ is the $y$-axis intercept. For a first-order reaction, we have

$$
\ln [\mathrm{A}]_{0}-\ln [\mathrm{A}]_{t}=k t
$$

Rearranging and changing signs gives

$$
\begin{aligned}
\ln [\mathrm{A}]_{t} & =-k t+\ln [\mathrm{A}]_{0} \\
y & =m x+b
\end{aligned}
$$

Therefore, a plot of $\ln [\mathrm{A}]_{t}$ vs. time gives a straight line with slope $=-k$ and $y$ intercept $=\ln [\mathrm{A}]_{0}$ (Figure 16.7A).

For a simple second-order reaction, we have

$$
\frac{1}{[\mathrm{~A}]_{t}}-\frac{1}{[\mathrm{~A}]_{0}}=k t
$$

Rearranging gives

$$
\begin{aligned}
\frac{1}{[\mathrm{~A}]_{t}} & =k t+\frac{1}{[\mathrm{~A}]_{0}} \\
y & =m x+b
\end{aligned}
$$

In this case, a plot of $1 /[\mathrm{A}]_{t}$ vs. time gives a straight line with slope $=k$ and $y$ intercept $=1 /[\mathrm{A}]_{0}$ (Figure 16.7B).

For a zero-order reaction, we have

$$
[\mathrm{A}]_{t}-[\mathrm{A}]_{0}=-k t
$$

Rearranging gives

$$
\begin{aligned}
{[\mathrm{A}]_{t} } & =-k t+[\mathrm{A}]_{0} \\
y & =m x+b
\end{aligned}
$$

Thus, a plot of $[\mathrm{A}]_{t}$ vs. time gives a straight line with slope $=-k$ and $y$ intercept $=[\mathrm{A}]_{0}$ (Figure 16.7 C ).

A First order

B Second order

C Zero order
Figure 16.7 Integrated rate laws and reaction orders. A, Plot of $\ln [A]_{t}$ vs. time gives a straight line for a reaction that is first order in A. B, Plot of $1 /[\mathrm{A}]_{t}$ vs. time gives a straight line for a reaction that is second order in A. C, Plot of $[\mathrm{A}]_{t}$ vs. time gives a straight line for a reaction that is zero order in A.

| Time <br> $(\min )$ | $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ | $\ln \left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ | $1 /\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ |
| :---: | :---: | :---: | :---: |
| 0 | 0.0165 | -4.104 | 60.6 |
| 10 | 0.0124 | -4.390 | 80.6 |
| 20 | 0.0093 | -4.68 | $1.1 \times 10^{2}$ |
| 30 | 0.0071 | -4.95 | $1.4 \times 10^{2}$ |
| 40 | 0.0053 | -5.24 | $1.9 \times 10^{2}$ |
| 50 | 0.0039 | -5.55 | $2.6 \times 10^{2}$ |
| 60 | 0.0029 | -5.84 | $3.4 \times 10^{2}$ |

Figure 16.8 Graphical determination of the reaction order for the decomposition of $\mathrm{N}_{2} \mathrm{O}_{5}$. A table of time and concentration data for determining reaction order appears below the graphs. A, A plot of [ $\mathrm{N}_{2} \mathrm{O}_{5}$ ] vs. time is curved, indicating that the reaction is not zero order in $\mathrm{N}_{2} \mathrm{O}_{5}$. B, A plot of $\ln \left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ vs. time gives a straight line, indicating that the reaction is first order in $\mathrm{N}_{2} \mathrm{O}_{5}$. C, A plot of $1 /\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ vs. time is curved, indicating that the reaction is not second order in $\mathrm{N}_{2} \mathrm{O}_{5}$. Plots A and $C$ support the conclusion from plot $B$.

Therefore, some trial-and-error graphical plotting is required to find the reaction order from the concentration and time data:

- If you obtain a straight line when you plot ln [reactant] vs. time, the reaction is first order with respect to that reactant.
- If you obtain a straight line when you plot $1 /[$ reactant $]$ vs. time, the reaction is second order with respect to that reactant.
- If you obtain a straight line when you plot [reactant] vs. time, the reaction is zero order with respect to that reactant.
 position of $\mathrm{N}_{2} \mathrm{O}_{5}$. Since the plot of $\ln \left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ is linear and the plot of $1 /\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ is not, the decomposition of $\mathrm{N}_{2} \mathrm{O}_{5}$ must be first order in $\mathrm{N}_{2} \mathrm{O}_{5}$.

## Reaction Half-Life

The half-life $\left(\boldsymbol{t}_{1 / 2}\right)$ of a reaction is the time required for the reactant concentration to reach half its initial value. A half-life is expressed in time units appropriate for a given reaction and is characteristic of that reaction at a given temperature.

At fixed conditions, the half-life of a first-order reaction is a constant, independent of reactant concentration. For example, the half-life for the first-order decomposition of $\mathrm{N}_{2} \mathrm{O}_{5}$ at $45^{\circ} \mathrm{C}$ is 24.0 min . The meaning of this value is that if we start with, say, $0.0600 \mathrm{~mol} / \mathrm{L}$ of $\mathrm{N}_{2} \mathrm{O}_{5}$ at $45^{\circ} \mathrm{C}$, after 24 min (one half-life), $0.0300 \mathrm{~mol} / \mathrm{L}$ has been consumed and $0.0300 \mathrm{~mol} / \mathrm{L}$ remains; after 48 min (two half-lives), $0.0150 \mathrm{~mol} / \mathrm{L}$ remains; after 72 min (three half-lives), $0.0075 \mathrm{~mol} / \mathrm{L}$ remains, and so forth (Figure 16.9).

We can see from the integrated rate law why the half-life of a first-order reaction is independent of concentration:

$$
\ln \frac{[\mathrm{A}]_{0}}{[\mathrm{~A}]_{t}}=k t
$$

After one half-life, $t=t_{1 / 2}$, and $[\mathrm{A}]_{t}=\frac{1}{2}[\mathrm{~A}]_{0}$. Substituting, we obtain

$$
\ln \frac{[\mathrm{A}]_{0}}{\frac{1}{2}[\mathrm{~A}]_{0}}=k t_{1 / 2} \quad \text { or } \quad \ln 2=k t_{1 / 2}
$$

Then, solving for $t_{1 / 2}$, we have

$$
\begin{equation*}
t_{1 / 2}=\frac{\ln 2}{k}=\frac{0.693}{k} \quad(\text { first-order process; rate }=k[\mathrm{~A}]) \tag{16.7}
\end{equation*}
$$

As you can see, the time to reach one-half the starting concentration in a firstorder reaction does not depend on what that starting concentration is.

Radioactive decay of an unstable nucleus is another example of a first-order process. For example, the half-life for the decay of uranium- 235 is $7.1 \times 10^{8}$ yr. After 710 million years, a sample containing 1 kg of uranium- 235 will contain 0.5 kg of uranium-235, and a sample containing 1 mg of uranium- 235 will contain 0.5 mg . (We discuss the kinetics ofradieactive deaythormhylinachaptee 24.) Whether we consider a molecule or a radioactive nucleus, the decomposition of each particle in a first-order process is independent of the number of other particles present.

We'll go through two sample problems to solidify this idea: the first generalizes the concept with molecular scenes, and the second uses real substances.

## SAMPLE PROBLEM 16.6 Using Molecular Scenes to Determine Half-Life

PROBLEM Compound A (red) converts to compound B (black) in a first-order process. The following scenes represent the reaction mixture at the start of the reaction (at 0.0 s ) and after 30.0 s :

(a) Find the half-life, $t_{1 / 2}$, of the reaction. (b) Calculate the rate constant, $k$. (c) Draw a scene that represents the reaction mixture after 2.00 min .
PLAN (a) Given that the reaction is first order, we know the half-life is a constant. Counting the numbers of red and black spheres at the start and at the later time tells us how fast the reaction is proceeding. When half of the red spheres have become black, the elapsed time is the half-life. (b) We substitute the value of $t_{1 / 2}$ from part (a) into Equation 16.7 and solve for $k$. (c) Once we know how long it takes half of A to become B, we can calculate how many red and black spheres would be in the mixture at 2.00 min (120. s).

Figure 16.9 A plot of $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right.$ ] vs. time for three half-lives. During each half-life, the concentration is halved ( $T=45^{\circ} \mathrm{C}$ and $\left.\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]_{0}=0.0600 \mathrm{~mol} / \mathrm{L}\right)$. The blow-up volumes, with $\mathrm{N}_{2} \mathrm{O}_{5}$ molecules as colored spheres, show that after three half-lives, $\frac{1}{2} \times \frac{1}{2} \times \frac{1}{2}=\frac{1}{8}$ of the original concentration remains.

SOLUTION (a) Examining the scenes to find $t_{1 / 2}$ : At $t=0.0 \mathrm{~s}$, there are 8 molecules of A (red) and no B (black). At $t=30.0 \mathrm{~s}, 6$ of A and 2 of B are present, so one-quarter of A has reacted. Therefore, it takes twice as long ( $2 \times 30.0 \mathrm{~s}$ ) for half of the original 8 molecules of A to react: $t_{1 / 2}=60.0 \mathrm{~s}$
(b) Finding the rate constant:

$$
\begin{aligned}
t_{1 / 2} & =0.693 / k \\
\text { therefore, } \quad k=0.693 / t_{1 / 2} & =0.693 / 60
\end{aligned}
$$

(c) If half of the original number of molecules react in 60.0 s , half of the remaining number react in two half-lives, or 120. s. The scene representing the mixture after 120. s is

CHECK For (b), rounding gives $0.7 / 60 \mathrm{~s}^{-1}$, which is slightly greater than $1 \times 10^{-2} \mathrm{~s}^{-1}$, so the answer seems correct.

FOLLOW-UP PROBLEM 16.6 Compound $X$ (blue) undergoes a slow first-order transformation to Y (orange), as represented by the scenes below:

Determine $t_{1 / 2}$ and $k$ of the reaction.

## SAMPLE PROBLEM 16.7 Determining the Half-Life of a First-Order Reaction

PROBLEM Cyclopropane is the smallest cyclic hydrocarbon. Because its $60^{\circ}$ bond angles reduce orbital overlap, its bonds are weak. As a result, it is thermally unstable and rearranges to propene at $1000^{\circ} \mathrm{C}$ via the following first-order reaction:

The rate constant is $9.2 \mathrm{~s}^{-1}$. (a) What is the half-life of the reaction? (b) How long does it take for the concentration of cyclopropane to reach one-quarter of the initial value? PLAN (a) The cyclopropane rearrangement is first order, so to find $t_{1 / 2}$ we use Equation 16.7 and substitute for $k\left(9.2 \mathrm{~s}^{-1}\right)$. (b) Each half-life decreases the concentration to onehalf of its initial value, so two half-lives decrease it to one-quarter.
SOLUTION (a) Solving for $t_{1 / 2}$ :

$$
t_{1 / 2}=\frac{\ln 2}{k}=\frac{0.693}{9.2 \mathrm{~s}^{-1}}=0.075 \mathrm{~s}
$$

It takes 0.075 s for half the cyclopropane to form propene at this temperature.
(b) Finding the time to reach one-quarter of the initial concentration:

$$
\text { Time }=2\left(t_{1 / 2}\right)=2(0.075 \mathrm{~s})=0.15 \mathrm{~s}
$$

CHECK For (a), rounding gives $0.7 / 9 \mathrm{~s}^{-1}=0.08 \mathrm{~s}$, so the answer seems correct.
FOLLOW-UP PROBLEM 16.7 Iodine-123 is used to study thyroid gland function. This radioactive isotope breaks down in a first-order process with a half-life of 13.1 h . What is the rate constant for the process?

| Table 16.4 | An Overview of Zero-Order, First-Order, and Simple <br> Second-Order Reactions |  |  |
| :--- | :--- | :--- | :--- |
|  | Zero Order | First Order | Second Order |
| Rate law | rate $=k$ | rate $=k[\mathrm{~A}]$ | rate $=k[\mathrm{~A}]^{2}$ |
| Units for $k$ | mol/L $\cdot \mathrm{s}$ | $1 / \mathrm{s}$ | $\mathrm{L} / \mathrm{mol} \cdot \mathrm{s}$ |
| Integrated rate law in | $[\mathrm{A}]_{t}=$ | $\ln [\mathrm{A}]_{t}=$ | $1 /[\mathrm{A}]_{t}=$ |
| straight-line form | $-k t+[\mathrm{A}]_{0}$ | $-k t+\ln [\mathrm{A}]_{0}$ | $k t+1 /[\mathrm{A}]_{0}$ |
| Plot for straight line | $[\mathrm{A}]_{t} \mathrm{vs.time}$ | $\ln [\mathrm{~A}]_{t} \mathrm{vs}$ time | $1 /[\mathrm{A}]_{t} \mathrm{vs}$ time |
| Slope, $y$ intercept | $-k,[\mathrm{~A}]_{0}$ | $-k, \ln [\mathrm{~A}]_{0}$ | $k, 1 /[\mathrm{A}]_{0}$ |
| Half-life | $[\mathrm{A}]_{0} / 2 k$ | $(\ln 2) / k$ | $1 / k[\mathrm{~A}]_{0}$ |

In contrast to the half-life of a first-order reaction, the half-life of a secondorder reaction does depend on reactant concentration:

$$
t_{1 / 2}=\frac{1}{k[\mathrm{~A}]_{0}} \quad\left(\text { second-order process; rate }=k[\mathrm{~A}]^{2}\right)
$$

Note that here the half-life is inversely proportional to the initial reactant concentration. This relationship means that a second-order reaction with a high initial reactant concentration has a shorter half-life, and one with a low initial reactant concentration has a longer half-life. Therefore, as a second-order reaction proceeds, the half-life increases.

In contrast to the half-life of a second-order reaction, the half-life of a zeroorder reaction is directly proportional to the initial reactant concentration:

$$
t_{1 / 2}=\frac{[\mathrm{A}]_{0}}{2 k} \quad \begin{aligned}
& \text { (zero-order process; } \\
& \text { Apate }
\end{aligned}=k \text { ) }
$$

Thus, if a zero-order reaction begins with a high reactant concentration, it has a longer half-life than if it begins with a low reactant concentration. Table 16.4 summarizes the essential features of zero-, first-, and second-order reactions.

## Section Summary

Integrated rate laws are used to find either the time needed to reach a certain concentration of reactant or the concentration present after a given time. Rearrangements of the integrated rate laws allow us to determine reaction orders and rate constants graphically. - The half-life is the time needed for the reaction to consume half the reactant; for first-order reactions, it is independent of concentration.

### 16.5 THE EFFECT OF TEMPERATURE ON REACTION RATE

Temperature often has a major effect on reaction rate. As Figure 16.10A shows for a common organic reaction (hydrolysis, or reaction with water, of an ester), when reactant concentrations are held constant, the rate nearly doubles with each rise in temperature of 10 K (or $10^{\circ} \mathrm{C}$ ). In fact, for many reactions near room temperature, an increase of $10^{\circ} \mathrm{C}$ causes a doubling or tripling of the rate.

| Expt | $[$ Ester $]$ | $\left[\mathrm{H}_{2} \mathrm{O}\right]$ | $T(\mathrm{~K})$ | Rate <br> $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ | $k$ <br> $(\mathrm{~L} / \mathrm{mol} \cdot \mathrm{s})$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 0.100 | 0.200 | 288 | $1.04 \times 10^{-3}$ | 0.0521 |
| 2 | 0.100 | 0.200 | 298 | $2.02 \times 10^{-3}$ | 0.101 |
| 3 | 0.100 | 0.200 | 308 | $3.68 \times 10^{-3}$ | 0.184 |
| 4 | 0.100 | 0.200 | 318 | $6.64 \times 10^{-3}$ | 0.332 |

Figure 16.10 Dependence of the rate constant on temperature. A, In the hydrolysis of the ester ethyl acetate,
$\mathrm{CH}_{3} \mathrm{COOCH}_{2} \mathrm{CH}_{3}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons$ $\mathrm{CH}_{3} \mathrm{COOH}+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$
when reactant concentrations are held constant and temperature increases, the rate and rate constant increase. Note the near doubling of $k$ with each rise of 10 K $\left(10^{\circ} \mathrm{C}\right)$. B, A plot of rate constant vs. temperature for this reaction shows an exponentially increasing curve.

Figure 16.11 Graphical determination of the activation energy. A plot of $\ln k$ vs. $1 / T$ gives a straight line with slope $=$ $-E_{\mathrm{a}} / R$.

The Significance of $R$ The importance of $R$ extends beyond the study of gases (or osmotic pressure). By expressing pressure and volume in more fundamental quantities, we obtain dimensions for energy, $E$ : $P=\frac{\text { force }}{\text { area }}=\frac{\text { force }}{(\text { length })^{2}} \quad V=(\text { length })^{3}$ Thus,

$$
\begin{aligned}
P V & =\frac{\text { force }}{(\text { length })^{2}} \times(\text { length })^{3} \\
& =\text { force } \times \text { length }
\end{aligned}
$$

Energy is used when a force moves an object over a distance. Thus,

$$
E=\text { force } \times \text { distance (or length) }
$$

so

$$
P V=\text { force } \times \text { length }=E
$$

Solving for $R$ in the ideal gas law and substituting for $P V$, we obtain

$$
R=\frac{P V}{n T}=\frac{E}{\text { amount } \times T}
$$

Thus, $R$ is the proportionality constant that relates the energy, amount (mol), and temperature of any chemical system.

Aside from mammals and birds, most animals-all reptiles and many species of amphibians, insects, and fish-absorb heat from the external environment to maintain metabolic and physical activity. For example, lizards and crocodiles bask in the sun or lie in the shade to regulate their internal reaction rates.

How does the rate law express this effect of temperature? If we collect concentration and time data for the same reaction run at different temperatures $(T)$, and then solve each rate expression for $k$, we find that $k$ increases as $T$ increases. In other words, temperature affects the rate by affecting the rate constant. A plot of $k$ vs. $T$ gives a curve that increases exponentially (Figure 16.10B).

These results are consistent with studies made in 1889 by the Swedish chemist Svante Arrhenius, who discovered a key relationship between $T$ and $k$. In its modern form, the Arrhenius equation is

$$
\begin{equation*}
k=A e^{-E_{\mathrm{a}} / R T} \tag{16.8}
\end{equation*}
$$

where $k$ is the rate constant, $e$ is the base of natural logarithms, $T$ is the absolute temperature, and $R$ is the universal gas constant. We'll discuss the meaning of the constant $A$, which is related to the orientation of the colliding molecules, in the next section. The $\boldsymbol{E}_{\mathbf{a}}$ term is the activation energy of the reaction, which Arrhenius considered the minimum energy the molecules must have to react; we'll explore its meaning in the next section as well. This negative exponential relationship between $T$ and $k$ means that as $T$ increases, the negative exponent becomes smaller, so the value of $k$ becomes larger, which means that the rate increases:

$$
\text { Higher } T \Longrightarrow \text { larger } k \Longrightarrow \text { increased rate }
$$

We can calculate $E_{\mathrm{a}}$ from the Arrhenius equation by taking the natural logarithm of both sides and recasting the equation into one for a straight line:
$\begin{aligned} & \text { ERNance } \\ & \ln k=\ln A-\frac{E_{\mathrm{a}}}{R}\left(\frac{1}{T}\right) \\ & y=b+m x\end{aligned}$
A plot of $\ln k$ vs. $1 / T$ gives a straight line whose slope is $-E_{\mathrm{a}} / R$ and whose $y$ intercept is $\ln A$ (Figure 16.11). Therefore, with the constant $R$ known, we can determine $E_{\mathrm{a}}$ graphically from a series of $k$ values at different temperatures.

Since the relationship between $\ln k$ and $1 / T$ is linear, we can use a simpler method to find $E_{\mathrm{a}}$ if we know the rate constants at two temperatures, $T_{2}$ and $T_{1}$ :

$$
\ln k_{2}=\ln A-\frac{E_{\mathrm{a}}}{R}\left(\frac{1}{T_{2}}\right) \quad \ln k_{1}=\ln A-\frac{E_{\mathrm{a}}}{R}\left(\frac{1}{T_{1}}\right)
$$

When we subtract $\ln k_{1}$ from $\ln k_{2}$, the term $\ln A$ drops out and the other terms can be rearranged to give

$$
\begin{equation*}
\ln \frac{k_{2}}{k_{1}}=-\frac{E_{\mathrm{a}}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right) \tag{16.9}
\end{equation*}
$$

From this, we can solve for $E_{\mathrm{a}}$.

## SAMPLE PROBLEM 16.8 Determining the Energy of Activation

PROBLEM The decomposition of hydrogen iodide,

$$
2 \mathrm{HI}(g) \longrightarrow \mathrm{H}_{2}(g)+\mathrm{I}_{2}(g)
$$

has rate constants of $9.51 \times 10^{-9} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$ at 500 . K and $1.10 \times 10^{-5} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$ at 600 . K . Find $E_{\mathrm{a}}$.

PLAN We are given the rate constants, $k_{1}$ and $k_{2}$, at two temperatures, $T_{1}$ and $T_{2}$, so we substitute into Equation 16.9 and solve for $E_{\text {a }}$.
SOLUTION Rearranging Equation 16.9 to solve for $E_{\mathrm{a}}$ :

$$
\begin{aligned}
\ln \frac{k_{2}}{k_{1}} & =-\frac{E_{\mathrm{a}}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right) \\
E_{\mathrm{a}} & =-R\left(\ln \frac{k_{2}}{k_{1}}\right)\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right)^{-1} \\
& =-(8.314 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})\left(\ln \frac{1.10 \times 10^{-5} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{~s}}{9.51 \times 10^{-9} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{~s}}\right)\left(\frac{1}{600 . \mathrm{K}}-\frac{1}{500 . \mathrm{K}}\right)^{-1} \\
& =1.76 \times 10^{5} \mathrm{~J} / \mathrm{mol} \\
& =1.76 \times 10^{2} \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

COMMENT Be sure to retain the same number of significant figures in $1 / T$ as you have in $T$, or a significant error could be introduced. Round to the correct number of significant figures only at the final answer. On most pocket calculators, the expression $\left(1 / T_{2}-1 / T_{1}\right)$ is entered as follows: $\left(T_{2}\right)(1 / x)-\left(T_{1}\right)(1 / x)=$
FOLLOW-UP PROBLEM 16.8 The reaction

$$
2 \mathrm{NOCl}(g) \longrightarrow 2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g)
$$

has an $E_{\mathrm{a}}$ of $1.00 \times 10^{2} \mathrm{~kJ} / \mathrm{mol}$ and a rate constant of $0.286 \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$ at $500 . \mathrm{K}$. What is the rate constant at 490 . K ?

In this section and Sections 16.3 and 16.4 , we discussed a series of experimental and mathematical methods for the study of reaction kinetics. Figure 16.12 presents a useful summary of this information. Notice that the integrated rate law provides an alternative method for obtaining reaction orders and the rate constant.

Apago PDF Enhancer

## Section Summary

As the Arrhenius equation shows, rate increases with temperature because a temperature rise increases the rate constant. - The activation energy, $E_{\mathrm{a}}$, the minimum energy needed for a reaction to occur, can be determined graphically from $k$ values at different $T$ values.

Figure 16.12 Information sequence to determine the kinetic parameters of a reaction. Note that the integrated rate law does not depend on the experimental comparison of initial rates and that it is also used to determine reaction orders and the rate constant.

Figure 16.13 The dependence of number of possible collisions on the product of reactant concentrations. Concentrations are multiplied, not added, in the rate law because the number of possible collisions is the product, not the sum, of the numbers of particles present.

### 16.6 EXPLAINING THE EFFECTS OF CONCENTRATION AND TEMPERATURE

The Arrhenius equation was developed empirically from the observations of many reactions. The two major models that explain the observed effects of concentration and temperature on reaction rate highlight different aspects of the reaction process but are completely compatible. Collision theory views the reaction rate as the result of particles colliding with a certain frequency and minimum energy. Transition state theory offers a close-up view of how the energy of a collision converts reactant to product.

## Collision Theory: Basis of the Rate Law

The basic tenet of collision theory is that reactant particles-atoms, molecules, and ions-must collide with each other to react. Therefore, the number of collisions per unit time provides an upper limit on how fast a reaction can take place. The model restricts itself to simple one-step reactions in which two particles collide and form products: $\mathrm{A}+\mathrm{B} \longrightarrow$ products. With its emphasis on collisions between three-dimensional particles, this model explains why reactant concentrations are multiplied together in the rate law, how temperature affects the rate, and what influence molecular structure has on rate.
Why Concentrations Are Multiplied in the Rate Law If particles must collide to react, the laws of probability tell us why the rate depends on the product of the reactant concentrations, not their sum. Imagine that you have only two particles of A and two of B confined in a reaction vessel. Figure 16.13 shows that four A-B collisions are possible. If you add another particle of $A$, there can be six A-B collisions $(3 \times 2)$, notjust five 31 2) indd anather particle of $B$, and there can be nine A-B collisions $(3 \times 3)$, not just six $\left(3^{-}+3\right)$. Thus, collision theory is consistent with the observation that concentrations are multiplied in the rate law.
How Temperature Affects Rate: The Importance of Activation Energy Increasing the temperature of a reaction increases the average speed of particles and therefore their collision frequency. But collision frequency cannot be the only factor affecting rate, or every gaseous reaction would be almost instantaneous: after all, at 1 atm and $20^{\circ} \mathrm{C}$, the molecules in a milliliter of gas experience about $10^{27}$ collisions per second, or about $4 \times 10^{7}$ collisions/molecule, so their reaction would be over in less than 1 ten-millionth of a second! In fact, in the vast majority of collisions, the molecules rebound without reacting.

Arrhenius proposed that every reaction has an energy threshold that the colliding molecules must exceed in order to react. (An analogy might be an athlete who must exceed the height of the bar to accomplish a high jump.) This minimum collision energy is the activation energy $\left(E_{\mathrm{a}}\right)$, the energy required to activate the molecules into a state from which reactant bonds can change into product bonds. Recall that at any given temperature, molecules have a range of kinetic energies; thus, their collisions have a range of energies as well. According to collision theory, only those collisions with enough energy to exceed $E_{\mathrm{a}}$ can lead to reaction.

We noted earlier that many reactions near room temperature approximately double or triple their rates with a $10^{\circ} \mathrm{C}$ rise in temperature. Is the rate increase due to a higher number of collisions? Actually, this has only a minor effect. Calculations show that a $10^{\circ} \mathrm{C}$ rise increases the average molecular speed by only $2 \%$. If an increase in speed is the only effect of temperature and if the speed of each colliding molecule increases by $2 \%$, we should observe at most a $4 \%$ increase in rate. Far more important is that the temperature rise enlarges the fraction of collisions with enough energy to exceed the activation energy. This key point is shown in Figure 16.14.

Figure 16.14 The effect of temperature on the distribution of collision energies. At the higher temperature, $T_{2}$, a larger fraction of collisions occur with enough energy to exceed $E_{\mathrm{a}}$.

At a given temperature, the fraction $f$ of molecular collisions with energy greater than or equal to the activation energy, $E_{\mathrm{a}}$, is given by

$$
f=e^{-E_{\|} / R T}
$$

where $e$ is the base of natural logarithms, $T$ is the absolute temperature, and $R$ is the universal gas constant. [Notice that the right side of this equation is the central component in the Arrhenius equation (Equation 16.8).] The magnitudes of both $E_{\mathrm{a}}$ and $T$ affect the fraction of sufficiently energetic collisions. In the top portion of Table 16.5, you can see the effect on this fraction of increasing $E_{\mathrm{a}}$ at a
 in activation energy. (As the height of the bar is raised, fewer athletes can accomplish the jump.) In the bottom portion of the table, you can see the effect on the fraction of increasing $T$ at a fixed $E_{\mathrm{a}}$ of $50 \mathrm{~kJ} / \mathrm{mol}$, a typical value for many reactions. Note that the fraction nearly doubles for a $10^{\circ} \mathrm{C}$ increase. Doubling the fraction doubles the rate constant, which doubles the reaction rate.

A reversible reaction has two activation energies (Figure 16.15). The activation energy for the forward reaction, $E_{\text {a(fwd) }}$, is the energy difference between the activated state and the reactants; the activation energy for the reverse reaction, $E_{\mathrm{a}(\text { rev })}$, is the energy difference between the activated state and the products. The figure shows an energy-level diagram for an exothermic reaction, so the products are at a lower energy than the reactants, and $E_{\mathrm{a}(\mathrm{fwd})}$ is less than $E_{\mathrm{a}(\mathrm{rev})}$.

Figure 16.15 Energy-level diagram for a reaction. For molecules to react, they must collide with enough energy to reach an activated state. This minimum collision energy is the energy of activation, $E_{\text {a }}$. A reaction can occur in either direction, so the diagram shows two activation energies. Here, the forward reaction is exothermic, and $E_{\mathrm{a}(\text { fwd })}<E_{\mathrm{a}(\mathrm{rev})}$.

Table 16.5 The Effect of $E_{\mathrm{a}}$ and $T$ on the Fraction ( $f$ ) of Collisions with Sufficient Energy to Allow Reaction

| $E_{\mathrm{a}}(\mathrm{kJ} / \mathrm{mol})$ | $f($ at $T=\mathbf{2 9 8} \mathrm{K})$ |
| :---: | :---: |
| 50 | $1.70 \times 10^{-9}$ |
| 75 | $7.03 \times 10^{-14}$ |
| 100 | $2.90 \times 10^{-18}$ |
| $T$ | $f\left(\right.$ at $\left.E_{\mathrm{a}}=\mathbf{5 0} \mathrm{kJ} / \mathrm{mol}\right)$ |
| $25^{\circ} \mathrm{C}(298 \mathrm{~K})$ | $1.70 \times 10^{-9}$ |
| $35^{\circ}(308 \mathrm{~K})$ | $3.29 \times 10^{-9}$ |
| $45^{\circ} \mathrm{C}(318 \mathrm{~K})$ | $6.12 \times 10^{-9}$ |

Figure 16.16 An energy-level diagram of the fraction of collisions whose energy exceeds $E_{\mathrm{a}}$. When Figure 16.14 is aligned vertically on the left and right axes of Figure 16.15, we see that

- In either direction, the fraction of collisions with energy exceeding $E_{\mathrm{a}}$ is larger at the higher $T$.
- In an exothermic reaction at any temperature, the fraction of collisions with energy exceeding $E_{\text {a(fwd) }}$ is larger than the fraction exceeding $E_{\mathrm{a} \text { (rev) }}$.

By turning the collision-energy distribution curve of Figure 16.14 vertically and aligning it on both sides of Figure 16.15, we obtain Figure 16.16, which shows how temperature affects the fraction of collisions that have energy exceeding the activation energy for both the forward and reverse reactions. Several ideas are illustrated in this composite figure:

- In both reaction directions, a larger fraction of collisions exceeds the activation energy at the higher temperature, $T_{2}$ : higher $T$ increases reaction rate.
- For an exothernis process (froward reaction here) at any temperature, the frac-

AionsIeactant colfisions" whthentex xceding $E_{\text {a(fwd }}$ is larger than the fraction of product collisions with energy exceeding $E_{\text {a(rev })}$; thus, the forward reaction is faster. On the other hand, in an endothermic process (reverse reaction here), $E_{\text {a(fwd) }}$ is greater than $E_{\text {a(rev) }}$, so the fraction of product collisions with energy exceeding $E_{\text {a(rev) }}$ is larger, and the reverse reaction is faster.
These conclusions are consistent with the Arrhenius equation; that is, the smaller the $E_{\mathrm{a}}$ (or the higher the temperature), the larger the value of $k$, and the faster the reaction:

Smaller $E_{\mathrm{a}}$ (or higher $T$ ) $\Longrightarrow$ larger $k \Longrightarrow$ increased rate
Conversely, the larger the $E_{\mathrm{a}}$ (or the lower the temperature), the smaller the value of $k$, and the slower the reaction:

$$
\text { Larger } \left.E_{\mathrm{a}} \text { (or lower } T\right) \Longrightarrow \text { smaller } k \Longrightarrow \text { decreased rate }
$$

How Molecular Structure Affects Rate You've seen that the enormous number of collisions per second is greatly reduced when we count only those with enough energy to react. However, even this tiny fraction of the total collisions does not reveal the true number of effective collisions, those that actually lead to product. In addition to colliding with enough energy, the molecules must collide so that the reacting atoms make contact. In other words, to be effective, a collision must have enough energy and a particular molecular orientation.

In the Arrhenius equation, the effect of molecular orientation is contained in the term $A$ :

$$
k=A e^{-E_{\mathrm{v}} / R T}
$$

This term is called the frequency factor, the product of the collision frequency $Z$ and an orientation probability factor, $p$, which is specific for each reaction: $A=p Z$. The factor $p$ is related to the structural complexity of the colliding particles. You can think of it as the ratio of effectively oriented collisions to all possible
collisions. For example, Figure 16.17 shows a few of the possible collision orientations for the following simple gaseous reaction:

$$
\mathrm{NO}(g)+\mathrm{NO}_{3}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

Of the five collisions shown, only one has an orientation in which the N of NO makes contact with an O of $\mathrm{NO}_{3}$. Actually, the orientation probability factor ( $p$ value) for this reaction is 0.006 : only 6 collisions in every 1000 ( 1 in 167) have an orientation that can lead to reaction.

Collisions between individual atoms have $p$ values near 1 : almost no matter how they hit, as long as the collision has enough energy, the particles react. In such cases, the rate constant depends only on the frequency and energy of the collisions. At the other extreme are biochemical reactions, in which the reactants are often two small molecules that can react only when they collide with a specific tiny region of a giant molecule-a protein or nucleic acid. The orientation probability factor for these reactions is often less than $10^{-6}$ : fewer than one in a million sufficiently energetic collisions lead to product. The fact that countless such biochemical reactions are occurring right now, as you read this sentence, helps make the point that the number of collisions per second is truly astounding.

## Transition State Theory: Molecular Nature of the Activated Complex

Collision theory is a simple, easy to visualize model, but it provides no insight about why the activation energy is crucial and how the activated molecules look. To understand these aspects of the process, we turn to transition state theory, which focuses on the high-energy species that forms through an effective collision.
Visualizing the Transition State Recall from our discussion of energy changes (Chapter 6) that the internal energy of a system is the sum of its kinetic and potential energies. When two moleculeszappreach achpother, somenkiticenergyis converted to potential energy as the electron clouds repel each other. At the moment of a head-on collision, the molecules stop, and their kinetic energy is converted to the potential energy of the collision. If this potential energy is less than the activation energy, the molecules recoil, bouncing off each other like billiard balls; the molecules zoom apart without reacting.

The tiny fraction of molecules that are oriented effectively and moving at the highest speed behave differently. Their kinetic energy pushes them together with enough force to overcome repulsions and react. Nuclei in one atom attract electrons in another; atomic orbitals overlap and electron densities shift; some bonds lengthen and weaken while others start to form. At some point during this smooth transformation, what exists is neither reactant nor product but a transitional species with partial bonds. This extremely unstable species, which is called the transition state, or activated complex, exists only at the instant when the reacting system is highest in potential energy. Thus, the activation energy is the quantity needed to stretch and deform bonds in order to reach the transition state.

Because transition states cannot be isolated, our knowledge of them, until recently, came from reasoning and studies of analogous, more stable species. This situation is changing rapidly due to the pioneering work of Ahmed H. Zewail, who received the 1999 Nobel Prize in chemistry. He used lasers pulsing on the same femtosecond $\left(10^{-15}\right)$ timescale as bond vibrations to observe the detailed changes occurring when transition states form and decompose.

Consider the reaction between methyl bromide and hydroxide ion:

$$
\mathrm{CH}_{3} \mathrm{Br}+\mathrm{OH}^{-} \longrightarrow \mathrm{CH}_{3} \mathrm{OH}+\mathrm{Br}^{-}
$$

The electronegative bromine makes the carbon of methyl bromide partially positive. If the reactants are moving toward each other fast enough and are oriented effectively when they collide, the negatively charged oxygen in $\mathrm{OH}^{-}$approaches the carbon with enough energy to begin forming a $\mathrm{C}-\mathrm{O}$ bond, which causes the

Figure 16.17 The importance of molecular orientation to an effective collision.
Only one of the five orientations shown for the collision between NO and $\mathrm{NO}_{3}$ has the correct orientation to lead to product. In the effective orientation, contact occurs between the atoms that will become bonded in the product.

Figure 16.18 Nature of the transition state in the reaction between $\mathrm{CH}_{3} \mathrm{Br}$ and $\mathrm{OH}^{-}$. Note the partial (elongated) $\mathrm{C}-\mathrm{O}$ and $\mathrm{C}-\mathrm{Br}$ bonds and the trigonal bipyramidal shape of the transition state of this reaction.
$\mathrm{C}-\mathrm{Br}$ bond to weaken. In the transition state (Figure 16.18), C is surrounded by five atoms (trigonal bipyramidal), which never occurs in its stable compounds. This high-energy species has three normal $\mathrm{C}-\mathrm{H}$ bonds and two partial bonds, one from C to O and the other from C to Br . Reaching this transition state is no guarantee that the reaction will proceed to products. A transition state can change in either direction: if the $\mathrm{C}-\mathrm{O}$ bond continues to shorten and strengthen, products form; however, if the $\mathrm{C}-\mathrm{Br}$ bond becomes shorter and stronger again, the transition state reverts to reactants.

Depicting the Change with Reaction Energy Diagrams A useful way to depict the events we just described is with a reaction energy diagram, which shows the potential energy of the system during the reaction as a smooth curve. Figure 16.19 shows the reaction energy diagram for the reaction of $\mathrm{CH}_{3} \mathrm{Br}$ and $\mathrm{OH}^{-}$, and also includes electron density relief maps, structural formulas, and molecularscale views at various points during the change.

The horizontal axis, labeled "Reaction progress," indicates that reactants change to products from left to right. This reaction is exothermic, so reactants are higher in

Reactants

Figure 16.19 Reaction energy diagram for the reaction between $\mathrm{CH}_{3} \mathrm{Br}$ and $\mathrm{OH}^{-}$. A plot of potential energy vs. reaction progress shows the relative energy levels of reactants, products, and transition state joined by a curved line, as well as the activation energies of the
forward and reverse reactions and the heat of reaction. The electron density relief maps, structural formulas, and molecular-scale views depict the change at five points. Note the gradual bond forming and bond breaking as the system goes through the transition state.

energy than products. The diagram also shows activation energies for the forward and reverse reactions; in this case, $E_{\text {a(fwd) }}$ is less than $E_{\text {a(rev) }}$. This difference, which reflects the change in bond energies, equals the heat of reaction, $\Delta H_{\mathrm{rxn}}$ :

$$
\begin{equation*}
\Delta H_{\mathrm{rxn}}=E_{\mathrm{a}(\mathrm{fwd})}-E_{\mathrm{a}(\mathrm{rrev})} \tag{16.10}
\end{equation*}
$$

Transition state theory proposes that every reaction (and every step in an overall reaction) goes through its own transition state, from which it can continue in either direction. We imagine how a transition state might look by examining the reactant and product bonds that change. Figure 16.20 depicts reaction energy diagrams for two simple reactions. Note that the shape of the postulated transition state in each case is based on a specific collision orientation between the atoms that become bonded to farm the produetDF Enhancer

## SAMPLE PROBLEM 16.9 Drawing Reaction Energy Diagrams and Transition States

PROBLEM A key reaction in the upper atmosphere is

$$
\mathrm{O}_{3}(g)+\mathrm{O}(g) \longrightarrow 2 \mathrm{O}_{2}(g)
$$

The $E_{\mathrm{a}(\mathrm{fwd})}$ is 19 kJ , and the $\Delta H_{\mathrm{rxn}}$ for the reaction as written is -392 kJ . Draw a reaction energy diagram for this reaction, postulate a transition state, and calculate $E_{\mathrm{a}(\mathrm{rev})}$.
PLAN The reaction is highly exothermic $\left(\Delta H_{\mathrm{rxn}}=-392 \mathrm{~kJ}\right)$, so the products are much lower in energy than the reactants. The small $E_{\mathrm{a}(\mathrm{fwd})}(19 \mathrm{~kJ})$ means the energy of the reactants lies slightly below that of the transition state. We use Equation 16.10 to calculate $E_{\text {a(rev) }}$. To postulate the transition state, we sketch the species and note that one of the bonds in $\mathrm{O}_{3}$ weakens, and this partially bonded $O$ begins forming a bond to the separate O atom.
SOLUTION Solving for $E_{\mathrm{a}(\mathrm{rev})}$ :
So,

$$
\begin{aligned}
& \Delta H_{\mathrm{rxn}}=E_{\mathrm{a}(\mathrm{fwd})}-E_{\mathrm{a}(\mathrm{rev})} \\
& E_{\mathrm{a}(\mathrm{rev})}=E_{\mathrm{a}(\mathrm{fwd})}-\Delta H_{\mathrm{rxn}}=19 \mathrm{~kJ}-(-392 \mathrm{~kJ})=411 \mathrm{~kJ}
\end{aligned}
$$

The reaction energy diagram (not drawn to scale), with transition state, is

CHECK Rounding to find $E_{\text {a(rev) }}$ gives $\sim 20+390=410$.

Figure 16.20 Reaction energy diagrams and possible transition states for two reactions.
$\mathrm{A}, 2 \mathrm{NOCl}(g) \longrightarrow 2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g)$ (Despite the formula NOCl , the atom sequence is CINO.)
$\mathrm{B}, \mathrm{NO}(\mathrm{g})+\mathrm{O}_{3}(\mathrm{~g}) \longrightarrow \mathrm{NO}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})$

FOLLOW-UP PROBLEM 16.9 The following reaction energy diagram depicts another key atmospheric reaction. Label the axes, identify $E_{\text {a(fwd) }}, E_{\text {a(rev) }}$, and $\Delta H_{\mathrm{rxn}}$, draw and label the transition state, and calculate $E_{\text {a(rev) }}$ for the reaction.

## Section Summary

According to collision theory, reactant particles must collide to react, and the number of collisions depends on the product of the reactant concentrations. - At higher temperatures, more collisions have enough energy to exceed the activation energy $\left(E_{\mathrm{a}}\right)$. - The relative $E_{\mathrm{a}}$ values for the forward and the reverse reactions depend on whether the overall reaction is exothermic or endothermic. - Molecules must collide with an effective orientation for them to react, so structural complexity decreases rate.

- Transition state theory pictures the kinetic energy of the particles changing to potential energy during a collision. - Given a sufficiently energetic collision and an effective molecular orientation, the reactant species become an unstable transition state, which either forms product(s) or reverts to reactant(s). - A reaction energy diagram depicts the changing energy of the chemical system as it progresses from reactants through transition state(s) to products.

### 16.7 REACTION MECHANISMS: STEPS IN THE OVERALL REACTION

Imagine trying to figure out how a car works just by examining the body, wheels, and dashboard. It can't be done-you need to look under the hood and inside the engine to see how the parts fit together and function. Similarly, because our main purpose is to know how a reaction works at the molecular level, examining the overall balanced equation is not much help-we must "look under the yield arrow and inside the reaction" to see how reactants change into products.

When we do so, we find that most reactions occur through a reaction mechanism, a sequence of single reaction steps that sum to the overall reaction. For example, a possible mechanism for the overall reaction

$$
2 \mathrm{~A}+\mathrm{B} \longrightarrow \mathrm{E}+\mathrm{F}
$$

might involve these three simpler steps:
(1) $\mathrm{A}+\mathrm{B} \longrightarrow \mathrm{C}$
(2) $\mathrm{C}+\mathrm{A} \longrightarrow \mathrm{D}$
(3) $D \longrightarrow E+F$

Adding them together and canceling common substances, we obtain the overall equation:

$$
\mathrm{A}+\mathrm{B}+\mathrm{C}+\mathrm{A}+\mathrm{D} \longrightarrow \mathrm{C}+\mathrm{D}+\mathrm{E}+\mathrm{F} \quad \text { or } \quad 2 \mathrm{~A}+\mathrm{B} \longrightarrow \mathrm{E}+\mathrm{F}
$$

Note what happens to C and to D in this mechanism. C is a product in step 1 and a reactant in step 2 , and D is a product in 2 and a reactant in 3. Each functions
as a reaction intermediate, a substance that is formed and used up during the overall reaction. Reaction intermediates do not appear in the overall balanced equation but are absolutely essential for the reaction to occur. They are usually unstable relative to the reactants and products but are far more stable than transition states (activated complexes). Reaction intermediates are molecules with normal bonds and are sometimes stable enough to be isolated.

Chemists propose a reaction mechanism to explain how a particular reaction might occur, and then they test the mechanism. This section focuses on the nature of the individual steps and how they fit together to give a rate law consistent with experimental results.

## Elementary Reactions and Molecularity

The individual steps, which together make up a proposed reaction mechanism, are called elementary reactions (or elementary steps). Each describes a single molecular event, such as one particle decomposing or two particles colliding and combining. An elementary step is not made up of simpler steps.

An elementary step is characterized by its molecularity, the number of reactant particles involved in the step. Consider the mechanism for the breakdown of ozone in the stratosphere. The overall reaction is

$$
2 \mathrm{O}_{3}(\mathrm{~g}) \longrightarrow 3 \mathrm{O}_{2}(\mathrm{~g})
$$

A two-step mechanism has been proposed for this reaction. Notice that the two steps sum to the overall reaction. The first elementary step is a unimolecular reaction, one that involves the decomposition or rearrangement of a single particle:
(1) $\mathrm{O}_{3}(g) \longrightarrow \mathrm{O}_{2}(g)+\mathrm{O}(g)$

The second step is a bimolecular peationg ipwhich tworntielas reaet:r
(2) $\mathrm{O}_{3}(g)+\mathrm{O}(g) \longrightarrow 2 \mathrm{O}_{2}(g)$

Some termolecular elementary steps occur, but they are extremely rare because the probability of three particles colliding simultaneously with enough energy and with an effective orientation is very small. Higher molecularities are not known. Unless evidence exists to the contrary, it makes good chemical sense to propose only unimolecular or bimolecular reactions as the elementary steps in a reaction mechanism.

The rate law for an elementary reaction, unlike that for an overall reaction, can be deduced from the reaction stoichiometry. An elementary reaction occurs in one step, so its rate must be proportional to the product of the reactant concentrations. Therefore, we use the equation coefficients as the reaction orders in the rate law for an elementary step; that is, reaction order equals molecularity (Table 16.6). Remember that this statement holds only when we know that the reaction is elementary; you've already seen that for an overall reaction, the reaction orders must be determined experimentally.

| Table 16.6 | Rate Laws for General Elementary Steps |  |
| ---: | :--- | :--- |
| Elementary Step | Molecularity | Rate Law |
| $\mathrm{A} \longrightarrow$ product | Unimolecular | Rate $=k[\mathrm{~A}]$ |
| $2 \mathrm{~A} \longrightarrow$ product | Bimolecular | Rate $=k[\mathrm{~A}]^{2}$ |
| $\mathrm{~A}+\mathrm{B} \longrightarrow$ product | Bimolecular | Rate $=k[\mathrm{~A}][\mathrm{B}]$ |
| $2 \mathrm{~A}+\mathrm{B} \longrightarrow$ product | Termolecular | Rate $=k[\mathrm{~A}]^{2}[\mathrm{~B}]$ |

## SAMPLE PROBLEM 16.10 Determining Molecularity and Rate Laws for Elementary Steps

PROBLEM The following two reactions are proposed as elementary steps in the mechanism for an overall reaction:
(1) $\quad \mathrm{NO}_{2} \mathrm{Cl}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{Cl}(g)$
(2) $\mathrm{NO}_{2} \mathrm{Cl}(g)+\mathrm{Cl}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{Cl}_{2}(g)$
(a) Write the overall balanced equation.
(b) Determine the molecularity of each step.
(c) Write the rate law for each step.

PLAN We find the overall equation from the sum of the elementary steps. The molecularity of each step equals the total number of reactant particles. We write the rate law for each step using the molecularities as reaction orders.
SOLUTION (a) Writing the overall balanced equation:

$$
\begin{aligned}
\mathrm{NO}_{2} \mathrm{Cl}(g) & \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{Cl}(g) \\
\mathrm{NO}_{2} \mathrm{Cl}(g)+\mathrm{Cl}(g) & \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{Cl}_{2}(g) \\
\hline \mathrm{NO}_{2} \mathrm{Cl}(g)+\mathrm{NO}_{2} \mathrm{Cl}(g)+\mathrm{Cl}(g) & \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{Cl}(g)+\mathrm{NO}_{2}(g)+\mathrm{Cl}_{2}(g) \\
2 \mathrm{NO}_{2} \mathrm{Cl}(g) & \longrightarrow 2 \mathrm{NO}_{2}(g)+\mathrm{Cl}_{2}(g)
\end{aligned}
$$

(b) Determining the molecularity of each step: The first elementary step has only one reactant, $\mathrm{NO}_{2} \mathrm{Cl}$, so it is unimolecular. The second elementary step has two reactants, $\mathrm{NO}_{2} \mathrm{Cl}$ and Cl , so it is bimolecular.
(c) Writing rate laws for the elementary reactions:
(1) Rate $_{1}=k_{1}\left[\mathrm{NO}_{2} \mathrm{Cl}\right]$
(2) Rate $_{2}=k_{2}\left[\mathrm{NO}_{2} \mathrm{Cl}\right][\mathrm{Cl}]$

CHECK In part (a), be sure the equation is balanced; in part (c), be sure the substances in brackets are the reactants of each elementary step.
FOLLOW-UP PROBLEM 16.10 The following elementary steps constitute a proposed mechanism for a reaction:
(1)

$$
2 \mathrm{NO}(g) \longrightarrow \mathrm{N}_{2} \mathrm{O}_{2}(g)
$$

(2)
$2 \mathrm{H}_{2}(\mathrm{~g}) \longrightarrow 4 \mathrm{H}(\mathrm{g})$
(3) $\mathrm{N}_{2} \mathrm{O}_{2}(g)+\mathrm{H}(g) \longrightarrow \mathrm{N}_{2} \mathrm{O}(g)+\mathrm{HO}(g)$
(4) $2 \mathrm{HO}(g)+2 \mathrm{H}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(g)$
(5) $\mathrm{H}(g)+\mathrm{N}_{2} \mathrm{O}(g) \longrightarrow \mathrm{HO}(g)+\mathrm{N}_{2}(g)$
(a) Write the balanced equation for the overall reaction.
(b) Determine the molecularity of each step.
(c) Write the rate law for each step.

## The Rate-Determining Step of a Reaction Mechanism

All the elementary steps in a mechanism do not have the same rate. Usually, one of the elementary steps is much slower than the others, so it limits how fast the overall reaction proceeds. This step is called the rate-determining step (or ratelimiting step).

Because the rate-determining step limits the rate of the overall reaction, its rate law represents the rate law for the overall reaction. Consider the reaction between nitrogen dioxide and carbon monoxide:

$$
\mathrm{NO}_{2}(g)+\mathrm{CO}(g) \longrightarrow \mathrm{NO}(g)+\mathrm{CO}_{2}(g)
$$

If the overall reaction were an elementary reaction-that is, if the mechanism consisted of only one step-we could immediately write the overall rate law as

$$
\text { Rate }=k\left[\mathrm{NO}_{2}\right][\mathrm{CO}]
$$

However, as you saw in Sample Problem 16.3, experiment shows that the actual rate law is

$$
\text { Rate }=k\left[\mathrm{NO}_{2}\right]^{2}
$$

Based on this observation, we know immediately that the reaction shown cannot be elementary.

A proposed two-step mechanism is
(1) $\mathrm{NO}_{2}(g)+\mathrm{NO}_{2}(g) \longrightarrow \mathrm{NO}_{3}(g)+\mathrm{NO}(g) \quad$ [slow; rate determining]
(2) $\mathrm{NO}_{3}(g)+\mathrm{CO}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{CO}_{2}(g) \quad$ [fast]

Note that $\mathrm{NO}_{3}$ functions as a reaction intermediate in the mechanism. Rate laws for these elementary steps are
(1) Rate $_{1}=k_{1}\left[\mathrm{NO}_{2}\right]\left[\mathrm{NO}_{2}\right]=k_{1}\left[\mathrm{NO}_{2}\right]^{2}$
(2) Rate $_{2}=k_{2}\left[\mathrm{NO}_{3}\right][\mathrm{CO}]$

Note that if $k_{1}=k$, the rate law for the rate-determining step (step 1) is identical to the experimental rate law. Because the first step is slow, $\left[\mathrm{NO}_{3}\right]$ is very low; thus, the fast second step cannot increase the overall rate, and the reaction takes essentially as long as the first step. Here you can see one reason a reactant (in this case, CO ) has a reaction order of zero is that it takes part in the reaction only after the rate-determining step.

## Correlating the Mechanism with the Rate Law

Conjuring up a reasonable reaction mechanism is one of the most exciting aspects of chemical kinetics and can be a classic example of the use of the scientific method. We use observations and data from rate experiments to hypothesize what the individual steps might be and then test our hypothesis by gathering further evidence. If the evidence supports it, we continue to apply that mechanism; if not, we propose a new one. However, we can never prove, just from data, that a particular mechanism represents the actual chemical change, only that it is consistent with it.

Regardless of the elementary steps proposed for a mechanism, they must meet three criteria:
 not wind up with more (or fewer) reactants or products than are present in the balanced equation.
2. The elementary steps must be physically reasonable. As we noted, most steps should involve one reactant particle (unimolecular) or two (bimolecular). Steps with three reactant particles (termolecular) are very unlikely.
3. The mechanism must correlate with the rate law. Most importantly, a mechanism must support the experimental facts shown by the rate law, not the other way around.
Let's see how the mechanisms of several reactions conform to these criteria and how the elementary steps fit together.
Mechanisms with a Slow Initial Step We've already seen one mechanism with a rate-determining first step-that for the reaction of $\mathrm{NO}_{2}$ and CO . Another example is the reaction between nitrogen dioxide and fluorine gas:

$$
2 \mathrm{NO}_{2}(g)+\mathrm{F}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2} \mathrm{~F}(g)
$$

The experimental rate law is first order in $\mathrm{NO}_{2}$ and in $\mathrm{F}_{2}$ :

$$
\text { Rate }=k\left[\mathrm{NO}_{2}\right]\left[\mathrm{F}_{2}\right]
$$

The accepted mechanism for the reaction is
(1) $\mathrm{NO}_{2}(g)+\mathrm{F}_{2}(g) \longrightarrow \mathrm{NO}_{2} \mathrm{~F}(g)+\mathrm{F}(g) \quad$ [slow; rate determining]
(2) $\mathrm{NO}_{2}(g)+\mathrm{F}(g) \longrightarrow \mathrm{NO}_{2} \mathrm{~F}(g)$ [fast]

Molecules of reactant and product appear in both elementary steps. The free fluorine atom is a reaction intermediate.

Does this mechanism meet the three crucial criteria?

1. The elementary reactions sum to the balanced equation:

$$
\begin{aligned}
& \mathrm{NO}_{2}(g)+\mathrm{NO}_{2}(g)+\mathrm{F}_{2}(g)+\mathrm{F}(g) \\
\text { or } & \longrightarrow \mathrm{NO}_{2} \mathrm{~F}(g)+\mathrm{NO}_{2} \mathrm{~F}(g)+\mathrm{F}(g) \\
2 \mathrm{NO}_{2}(g)+\mathrm{F}_{2}(g) & \longrightarrow \mathrm{NO}_{2} \mathrm{~F}(g)
\end{aligned}
$$

2. Both steps are bimolecular, so they are chemically reasonable.
3. The mechanism gives the rate law for the overall equation. To show this, we write the rate laws for the elementary steps:
(1) Rate $_{1}=k_{1}\left[\mathrm{NO}_{2}\right]\left[\mathrm{F}_{2}\right]$
(2) Rate $_{2}=k_{2}\left[\mathrm{NO}_{2}\right][\mathrm{F}]$

Step 1 is the rate-determining step and therefore gives the overall rate law, with $k_{1}=k$. Because the second molecule of $\mathrm{NO}_{2}$ appears in the step that follows the rate-determining step, it does not appear in the overall rate law. Thus, we see that the overall rate law includes only species active in the reaction up to and including those in the rate-determining step. This point was also illustrated by the mechanism for $\mathrm{NO}_{2}$ and CO shown earlier. Carbon monoxide was absent from the overall rate law because it appeared after the rate-determining step.

Figure 16.21 is a reaction energy diagram for the reaction of $\mathrm{NO}_{2}$ and $\mathrm{F}_{2}$. Note that

- Each step in the mechanism has its own transition state. (Note that only one molecule of $\mathrm{NO}_{2}$ reacts in step 1, and only the first transition state is depicted.)
- The F atom intermediate is a reactive, unstable species (as you know from halogen chemistry), so it is higher in energy than the reactants or product.
- The first step is slower (rate limiting), so its activation energy is larger than that of the second step.
- The overall reaction is exothermic, so the product is lower in energy than the reactants.

Figure 16.21 Reaction energy diagram for the two-step reaction of $\mathrm{NO}_{2}$ and $\mathrm{F}_{2}$. Each step in the mechanism has its own transition state. The proposed transition state is shown for step 1. Reactants for the second step are the F atom intermediate and the second molecule of $\mathrm{NO}_{2}$. Note that the first step is slower (higher $E_{\mathrm{a}}$ ). The overall reaction is exothermic $\left(\Delta H_{\mathrm{rxn}}<0\right)$.

Mechanisms with a Fast Initial Step If the rate-limiting step in a mechanism is not the initial step, it acts as a bottleneck later in the reaction sequence. As a result, the product of a fast initial step builds up and starts reverting to reactant, while waiting for the slow step to remove it. With time, the product of the initial step is changing back to reactant as fast as it is forming. In other words, the fast initial step reaches equilibrium. As you'll see, this situation allows us to fit the mechanism to the overall rate law.

Consider once again the oxidation of nitrogen monoxide:

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

The experimentally determined rate law is

$$
\text { Rate }=k[\mathrm{NO}]^{2}\left[\mathrm{O}_{2}\right]
$$

and a proposed mechanism is
(1) $\mathrm{NO}(g)+\mathrm{O}_{2}(g) \rightleftharpoons \mathrm{NO}_{3}(g) \quad$ [fast, reversible]
(2) $\mathrm{NO}_{3}(g)+\mathrm{NO}(g) \longrightarrow 2 \mathrm{NO}_{2}(g) \quad$ [slow; rate determining]

Note that, with cancellation of the reaction intermediate $\mathrm{NO}_{3}$, the first criterion is met because the sum of the steps gives the overall equation. Also note that the second criterion is met because both steps are bimolecular.

To meet the third criterion (that the mechanism conforms to the overall rate law), we first write rate laws for the elementary steps:
(1) $\operatorname{Rate}_{1(\mathrm{fwd})}=k_{1}[\mathrm{NO}]\left[\mathrm{O}_{2}\right]$
$\operatorname{Rate}_{1(\mathrm{rev})}=k_{-1}\left[\mathrm{NO}_{3}\right]$
where $k_{-1}$ is the rate constant for the reverse reaction.
(2) Rate $_{2}=k_{2}\left[\mathrm{NO}_{3}\right][\mathrm{NO}]$

Now we must show that the rate law for the rate-determining step (step 2) gives the overall rate law. As written, it does not, because it contains the intermediate $\mathrm{NO}_{3}$, and an overall rate law can include only reactants (and products). Therefore, we must eliminate $\left[\mathrm{NO}_{3}\right]$ from the step 2 rate law. To do so, we express $\left[\mathrm{NO}_{3}\right]$ in terms of reactants. Step 1 reaches equilibrium when the forward and reverse rates are equal:

$$
\operatorname{Rate}_{1(\mathrm{fwd})}=\operatorname{Rate}_{1(\mathrm{rev})} \quad \text { or } \quad k_{1}[\mathrm{NO}]\left[\mathrm{O}_{2}\right]=k_{-1}\left[\mathrm{NO}_{3}\right]
$$

To express $\left[\mathrm{NO}_{3}\right]$ in terms of reactants, we isolate it algebraically:

$$
\left[\mathrm{NO}_{3}\right]=\frac{k_{1}}{k_{-1}}[\mathrm{NO}]\left[\mathrm{O}_{2}\right]
$$

Then, substituting for $\left[\mathrm{NO}_{3}\right]$ in the fate taw or step 2, we Fbannancer

$$
\operatorname{Rate}_{2}=k_{2}\left[\mathrm{NO}_{3}\right][\mathrm{NO}]=k_{2}\left(\frac{k_{1}}{k_{-1}}[\mathrm{NO}]\left[\mathrm{O}_{2}\right]\right)[\mathrm{NO}]=\frac{k_{2} k_{1}}{k_{-1}}\left[\mathrm{NO}^{2}\left[\mathrm{O}_{2}\right]\right.
$$

This rate law is identical to the overall rate law, with $k=\frac{k_{2} k_{1}}{k_{-1}}$.
Thus, to test the validity of a mechanism with a fast initial, reversible step:

1. Write rate laws for both directions of the fast step and for the slow step.
2. Show that the slow step's rate law is equivalent to the overall rate law, by expressing [intermediate] in terms of [reactant]: set the forward rate law of the fast, reversible step equal to the reverse rate law, and solve for [intermediate].
3. Substitute the expression for [intermediate] into the rate law for the slow step to obtain the overall rate law.
Several end-of-chapter problems, including Problems 16.72 and 16.73 , provide additional examples of this approach.

## Section Summary

The mechanisms of most common reactions consist of two or more elementary steps, reactions that occur in one step and depict a single chemical change. - The molecularity of an elementary step equals the number of reactant particles and is the same as the reaction order of its rate law. Unimolecular and bimolecular steps are common. - The rate-determining, or rate-limiting (slowest), step determines how fast the overall reaction occurs, and its rate law represents the overall rate law. - Reaction intermediates are species that form in one step and react in a later one. - The steps in a proposed mechanism must add up to the overall reaction, be physically reasonable, and conform to the overall rate law. If a fast step precedes a slow step, the fast step reaches equilibrium, and the concentrations of intermediates in the rate law of the slow step must be expressed in terms of reactants.

### 16.8 CATALYSIS: SPEEDING UP A CHEMICAL REACTION

There are many situations in which the rate of a reaction must be increased for it to be useful. In an industrial process, for example, a higher rate often determines whether a new product can be made economically. Sometimes, we can speed up a reaction sufficiently with a higher temperature, but energy is costly and many substances are heat sensitive and easily decomposed. Alternatively, we can often employ a catalyst, a substance that increases the rate without being consumed in the reaction. Because catalysts are not consumed, only very small, nonstoichiometric quantities are generally required. Nevertheless, these substances are employed in so many important processes that several million tons of industrial catalysts are produced annually in the United States alone! Nature is the master designer and user of catalysts. Even the simplest bacterium employs thousands of biological catalysts, known as enzymes, to speed up its cellular reactions. Every organism relies on enzymes to sustain life.

Each catalyst has its own specific way of functioning, but in general, a catalyst causes a lower activation energy, which in turn makes the rate constant larger and the rate higher. Two important points stand out in Figure 16.22:

- A catalyst speeds up the forward and reverse reactions. A reaction with a catalyst does not yield more product than one without a catalyst, but it yields the product more quickly.
- A catalyst causes a lower activation energy by providing a different mechanism for the reaction, and thus a new, lower energy pathway.
Consider a general uncatalyzed reaction that proceeds by a one-step mechanism involving a bimolecular collision:

In the catalyzed reaction, a reactant molecule interacts with the catalyst, so the mechanism might involve a two-step pathway:

$$
\begin{array}{ll}
\mathrm{A}+\text { catalyst } & \longrightarrow \mathrm{C} \\
\mathrm{C}+\mathrm{B} & \text { [faster] } \\
\text { product }+ \text { catalyst } & \text { [faster] }
\end{array}
$$

Figure 16.22 Reaction energy diagram for a catalyzed and an uncatalyzed process. A catalyst speeds a reaction by providing a new, lower energy pathway, in this case by replacing the one-step mechanism with a two-step mechanism. Both forward and reverse rates are increased to the same extent, so a catalyst does not affect the overall reaction yield. (The only activation energy shown for the catalyzed reaction is the larger one for the forward direction.)

Note that the catalyst is not consumed, as its definition requires. Rather, it is used and then regenerated, and the activation energies of both steps are lower than the activation energy of the uncatalyzed pathway.

Chemists recognize two general categories of catalyst-homogeneous and heterogeneous-based on whether the catalyst occurs in the same phase as the reactant and product.

## Homogeneous Catalysis

A homogeneous catalyst exists in solution with the reaction mixture. All homogeneous catalysts are gases, liquids, or soluble solids. Some industrial processes that employ these catalysts are shown in Table 16.7 (top).

A thoroughly studied example of homogeneous catalysis is the hydrolysis of an organic ester (RCOOR'), a reaction we examined in Section 15.4:

Here R and $\mathrm{R}^{\prime}$ are hydrocarbon groups, $\mathrm{R}-\mathrm{C}-\mathrm{OH}$ is a carboxylic acid, and $\mathrm{R}^{\prime}-\mathrm{OH}$ is an alcohol. The reaction rate is low at room temperature but can be increased greatly by adding a small amount of strong acid, which provides $\mathrm{H}^{+}$ ion, the catalyst in the reaction; strong bases, which supply $\mathrm{OH}^{-}$ions, also speed ester hydrolysis, but by a slightly different mechanism.

In the first step of the acid-catalyzed reaction (Figure 16.23), the $\mathrm{H}^{+}$of a hydronium ion forms a bond to the double-bonded O atom. From the resonance forms, we see that the bonding of $\mathrm{H}^{+}$then makes the C atom more positive, which increases its attraction for the partially negative © atom of Fwaten 热effect $\boldsymbol{H}^{+}$ increases the likelihood that the bonding of water, which is the rate-determining step, will take place. Several steps later, a water molecule, acting as a base, removes the $\mathrm{H}^{+}$and returns it to solution. Thus, $\mathrm{H}^{+}$acts as a catalyst because it speeds up the reaction but is not itself consumed: it is used up in one step and re-formed in another.

| Reactants | Catalyst | Product | Use |
| :---: | :---: | :---: | :---: |
| Homogeneous |  |  |  |
| Propylene, oxidizer | $\mathrm{Mo}(\mathrm{VI})$ complexes | Propylene oxide | Polyurethane foams; polyesters |
| Methanol, CO | $\left[\mathrm{Rh}(\mathrm{CO})_{2} \mathrm{I}_{2}\right]^{-}$ | Acetic acid | Poly(vinyl acetate) coatings; poly(vinyl alcohol) |
| Butadiene, HCN | $\mathrm{Ni} / \mathrm{P}$ compounds | Adiponitrile | Nylons (fibers, plastics) |
| $\alpha$-Olefins, $\mathrm{CO}, \mathrm{H}_{2}$ | $\mathrm{Rh} / \mathrm{P}$ compounds | Aldehydes | Plasticizers, lubricants |
| Heterogeneous |  |  |  |
| Ethylene, $\mathrm{O}_{2}$ | Silver, cesium chloride on alumina | Ethylene oxide | Polyesters, ethylene glycol, lubricants |
| Propylene, $\mathrm{NH}_{3}, \mathrm{O}_{2}$ | Bismuth molybdates | Acrylonitrile | Plastics, fibers, resins |
| Ethylene | Organochromium and titanium halides on silica | High-density polyethylene | Molded products |

Step 2

Steps 3-6

Figure 16.23 Mechanism for the catalyzed hydrolysis of an organic ester. In step 1, the catalytic $\mathrm{H}^{+}$ion binds to the electron-rich oxygen. The resonance hybrid of this product (see gray panel) shows the C atom is more positive than it would ordinarily be. The enhanced charge on C attracts the partially negative O of water more strongly, increasing the fraction of effective collisions and thus speeding up step 2, the rate-determining step. Loss of $\mathrm{R}^{\prime} \mathrm{OH}$ and removal of $\mathrm{H}^{+}$by water occur in a final series of fast steps.

Catalytically Cleaning Your Car's Exhaust A heterogeneous catalyst you use every day, but rarely see, is in the catalytic converter in your car's exhaust system. This device is designed to convert polluting exhaust gases into nontoxic ones. In a single pass through the catalyst bed, CO and unburned gasoline are oxidized to $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$, while NO is reduced to $\mathrm{N}_{2}$. As in the mechanism for catalytic hydrogenation of an alkene, the catalyst lowers the activation energy of the rate-determining step by adsorbing the molecules, thereby weakening their bonds. Mixtures of transition metals and their oxides embedded in inert supports convert as much exhaust gas as possible in the shortest time. It is estimated, for example, that an NO molecule is adsorbed and split into catalyst-bound N and O atoms in less than $2 \times 10^{-12} \mathrm{~s}$ !

Figure 16.24 The metal-catalyzed hydrogenation of ethene.

Many digestive enzymes, which catalyze the hydrolysis of proteins, fats, and carbohydrates during the digestion of foods, employ very similar mechanisms. The difference is that the acids or bases that speed these reactions are not the strong inorganic reagents used in the lab, but rather specific amino-acid side chains of the enzymes that release or abstract $\mathrm{H}^{+}$ions.

## Heterogeneous Catalysis

A heterogeneous catalyst speeds up a reaction that occurs in a separate phase. The catalyst is most often a solid interacting with gaseous or liquid reactants. Because reaction occurs on the solid's surface, heterogeneous catalysts usually have enormous surface areas for contact, between 1 and $500 \mathrm{~m}^{2} / \mathrm{g}$. Interestingly, many reactions that occur on a metal surface, such as the decomposition of HI on gold and the decomposition of $\mathrm{N}_{2} \mathrm{O}$ on platinum, are zero order because the rate-determining step occurs on the surface itself. Thus, despite an enormous surface area, once the reactant gas covers the surface, increasing the reactant concentration cannot increase the rate. Table 16.7 (bottom) lists some polymer manufacturing processes that employ heterogeneous catalysts.

One of the most important examples of heterogeneous catalysis is the addition of $\mathrm{H}_{2}$ to the $\mathrm{C}=\mathrm{C}$ bonds of organic compounds to form $\mathrm{C}-\mathrm{C}$ bonds. The petroleum, plastics, and food industries frequently use catalytic hydrogenation. The conversion of vegetable oil into margarine is one example.

The simplest hydrogenation converts ethylene (ethene) to ethane:

$$
\mathrm{H}_{2} \mathrm{C}=\mathrm{CH}_{2}(g)+\mathrm{H}_{2}(g) \longrightarrow \mathrm{H}_{3} \mathrm{C}-\mathrm{CH}_{3}(g)
$$

In the absence of a catalyst, the reaction occurs very slowly. At high $\mathrm{H}_{2}$ pressure in the presence of finely divided $\mathrm{Ni}, \mathrm{Pd}$, or Pt , the reaction becomes rapid even at ordinary temperatures. These Group $8 \mathrm{~B}(10)$ metals catalyze by chemically atsof ing the reftents ontindiauffee Fifgure 16.24). The $\mathrm{H}_{2}$ lands and splits into separate H atoms chemically bound to the solid catalyst's metal atoms (catM):

$$
\mathrm{H}-\mathrm{H}(g)+2 \operatorname{catM}(s) \longrightarrow 2 \mathrm{catM}-\mathrm{H}(\mathrm{H} \text { atoms bound to metal surface })
$$

Then, $\mathrm{C}_{2} \mathrm{H}_{4}$ adsorbs and reacts with two H atoms, one at a time, to form $\mathrm{C}_{2} \mathrm{H}_{6}$. The $\mathrm{H}-\mathrm{H}$ bond breakage is the rate-determining step in the overall process, and interaction with the catalyst's surface provides the low- $E_{\mathrm{a}}$ step as part of an alternative reaction mechanism.

Two Chemical Connections essays follow. The first introduces the remarkable catalytic abilities of the enzymes inside you, and the second discusses how catalysis operates in the depletion of stratospheric ozone.

(1) $\mathrm{H}_{2}$ adsorbs to metal surface

(3) After $\mathrm{C}_{2} \mathrm{H}_{4}$ adsorbs, one $\mathrm{C}-\mathrm{H}$ forms.

(2) Rate-limiting step is $\mathrm{H}-\mathrm{H}$ bond breakage.

(4) Another $\mathrm{C}-\mathrm{H}$ bond forms; $\mathrm{C}_{2} \mathrm{H}_{6}$ leaves surface.

## Chemical Connections to Enzymology <br> Kinetics and Function of Biological Catalysts

Within every living cell, thousands of individual reactions occur. Many involve complex chemical changes, yet they take place in dilute solution at ordinary temperatures and pressures. The rate of each reaction responds smoothly to momentary or permanent changes in other reaction rates, various signals from other cells, and environmental stresses. Virtually every reaction in this marvelous chemical harmony is catalyzed by its own specific enzyme, a protein catalyst whose function has been perfected through evolution.

Enzymes have complex three-dimensional shapes (see Section 15.6) and molar masses ranging from about 15,000 to $1,000,000 \mathrm{~g} / \mathrm{mol}$. At a specific region on an enzyme's surface is its
active site, a crevice whose shape results from the shapes of the amino acid side chains ( R groups) directly involved in catalyzing the reaction (also see Figure B10.4, p. 403). When the reactant molecules, called the substrates of the reaction, collide with the active site, the chemical change is initiated. The active site makes up only a small part of the enzyme's surface-like a tiny hollow carved into a mountainside-and often includes amino acid R groups from distant regions of the molecular chain that lie near each other because of the folding of the protein's backbone, as depicted in Figure B16.4. In most cases, substrates bind to the active site through intermolecular forces: H bonds, dipole forces, and other weak attractions.
(continued)

Figure B16.4 The widely separated amino acid groups that form an active site. The amino acids in chymotrypsin, a digestive enzyme, are shown as linked spheres and numbered consecutively from the beginning of the chain. The $R$ groups of the active-site amino acids 57 (histidine, His), 102 (aspartic acid, Asp), and 195 (serine, Ser) are
shown because they play a crucial role in the enzyme-catalyzed reaction. Part of the substrate molecule lies within the active site's crevice (binding pocket) to anchor it during reaction. (Illustration by Irving Geis. Rights owned by Howard Hughes Medical Institute. Not to be used without permission.)

Chemical Connections
An enzyme has features of both a homogeneous and a heterogeneous catalyst. Most enzymes are enormous compared with their substrates, and they are often found embedded within membranes of larger cell parts. Thus, like a heterogeneous catalyst, an enzyme provides an active surface on which a reactant is immobilized temporarily, waiting for its reaction partner to land nearby. Like a homogeneous catalyst, the enzyme's amino acid R groups interact actively with the substrates in multistep sequences involving intermediates.

Enzymes are incredibly efficient catalysts. Consider the hydrolysis of urea as an example:

$$
\begin{array}{r}
\left(\mathrm{NH}_{2}\right)_{2} \mathrm{C}=\mathrm{O}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{H}^{+}(a q) \xrightarrow[2 \mathrm{NH}_{4}^{+}(a q)]{\longrightarrow}+\mathrm{HCO}_{3}^{-}(a q)
\end{array}
$$

In water at room temperature, the rate constant for the uncatalyzed reaction is approximately $3 \times 10^{-10} \mathrm{~s}^{-1}$. Under the same conditions in the presence of the enzyme urease (pronounced "yur-eease"), the rate constant is $3 \times 10^{4} \mathrm{~s}^{-1}$, a $10^{14}$-fold increase! Enzymes increase rates by $10^{8}$ to $10^{20}$ times, values that industrial chemists who design catalysts can only dream of.

Enzymes are also extremely specific: each reaction is generally catalyzed by a particular enzyme. Urease catalyzes only the hydrolysis of urea, and none of the several thousand other enzymes present in the cell catalyzes that reaction. This remarkable specificity results from the particular groups that comprise the active site. Two models of enzyme action are illustrated in Figure B16.5. According to the lock-and-key model, when the "key" (substrate) fits the "lock" (active site), the chemical change begins. However, x-ray crystallographic and spectroscopic methods show that, in many cases, the enzyme changes shape when the substrate lands at the active site. This induced-fit mode of enzyme action pictures the substrate inducing the active site to adopt a perfect fit. Rather than a rigidly shaped lock and key, therefore, we should picture a hand in a glove, in which the "glove" (active site) does not attain its functional shape until the "hand" (substrate) moves into place.

Figure B16.5 Two models of enzyme action. A, In the lock-and-key model, the active site is thought to be an exact fit for the substrate shapes. $\mathbf{B}$, In the induced-fit model, the active site is thought to change shape to fit the substrates. Most enzyme-catalyzed reac-

The kinetics of enzyme catalysis has many features in common with that of ordinary catalysis. In an uncatalyzed reaction, the rate is affected by the concentrations of the reactants; in a catalyzed reaction, the rate is affected by the concentration of reactant bound to catalyst. In the enzyme-catalyzed case, substrate (S) and enzyme ( E ) form an intermediate enzyme-substrate complex (ES), whose concentration determines the rate of product ( P ) formation. The steps common to virtually all enzyme-catalyzed reactions are
$\mathrm{E}+\mathrm{S} \rightleftharpoons \mathrm{ES}$
[fast, reversible]
$\mathrm{ES} \longrightarrow \mathrm{E}+\mathrm{P}$
[slow; rate determining]
Thus, rate $=k[\mathrm{ES}]$. When all the available enzyme molecules are bound to substrate and exist as ES, increasing [S] has no effect on rate and the process is zero order. To cite one very common example, the breakdown of ethanol in the body is zero order.

Enzymes employ a variety of catalytic mechanisms. In some cases, the active-site R groups bring the reacting atoms of the bound substrates closer together. In other cases, the groups move apart slightly, stretching the substrate bond that is to be broken in the process. Some R groups are acidic and thus are able to provide $\mathrm{H}^{+}$ions that increase the speed of a rate-determining step; others act as bases and remove $\mathrm{H}^{+}$ions at a critical step. Hydrolases are a class of enzymes that cleave bonds by such acid-base catalysis. For example, lysozyme, an enzyme found in tears, hydrolyzes bacterial cell walls, thus protecting the eyes from microbes, and chymotrypsin, an enzyme found in the small intestine, hydrolyzes proteins into smaller molecules during digestion.

No matter what their specific mode of action, all enzymes function by stabilizing the reaction's transition state. For instance, in the fysozyme-eatalyzed reaction, the transition state is a sugar molecule whose bonds are twisted and stretched into unusual lengths and angles so that it fits the lysozyme active site perfectly. By stabilizing the transition state through binding it effectively, lysozyme lowers the activation energy of the reaction and thus increases the rate.

B Induced-fit model
tions proceed through the fast, reversible formation of an enzymesubstrate complex, followed by a slow conversion to product and free enzyme.

## Chemical Connections to Atmospheric Science <br> Depletion of Earth's Ozone Layer

Both homogeneous and heterogeneous catalysts play key roles in one of today's most serious environmental concerns-the depletion of ozone from the stratosphere. The stratospheric ozone layer absorbs UV radiation with wavelengths between 280 and 320 nm emitted by the Sun that would otherwise reach Earth's surface. This radiation (called UV-B) has enough energy to break bonds in deoxyribonucleic acid (DNA) and thereby damage genes. Depletion of stratospheric ozone could significantly increase risks to human health from UV-B, particularly a higher incidence of skin cancer and cataracts (loss of transparency of the lens of the eye). Plant life, especially the simpler forms at the base of the food chain, may also be damaged.

Before 1976, stratospheric ozone concentration varied seasonally but remained nearly constant from year to year through a series of atmospheric reactions. Oxygen atoms formed from dissociation of $\mathrm{O}_{2}$ by UV radiation with wavelengths less than 242 nm react with $\mathrm{O}_{2}$ to form $\mathrm{O}_{3}$, and with $\mathrm{O}_{3}$ to regenerate $\mathrm{O}_{2}$ :

$$
\begin{aligned}
\mathrm{O}_{2} & \longrightarrow \mathrm{UV} 2 \mathrm{O} \\
\mathrm{O}+\mathrm{O}_{2} & \longrightarrow \mathrm{O}_{3} \\
\mathrm{O}+\mathrm{O}_{3} & \longrightarrow 2 \mathrm{O}_{2}
\end{aligned} \quad \begin{aligned}
& \text { [ozone formation] } \\
& \text { [ozone breakdown] }
\end{aligned}
$$

However, research by Paul J. Crutzen, Mario J. Molina, and F. Sherwood Rowland, for which they received the Nobel Prize in chemistry in 1995, revealed that industrially produced chlorofluorocarbons (CFCs) shifted this balance by catalyzing the breakdown reaction.

CFCs were widely used as aerosol propellants, foam-blowing agents, and air-conditioning coolants, se large quantities yere released into the atmosphere. Unreactive in the tooposphere, CFC molecules gradually reach the stratosphere, where they encounter UV radiation that can split them and release chlorine atoms:

$$
\mathrm{CF}_{2} \mathrm{Cl}_{2} \xrightarrow{\mathrm{UV}} \mathrm{CF}_{2} \mathrm{Cl} \cdot+\mathrm{Cl} \cdot
$$

(The dots are unpaired electrons resulting from bond cleavage.)
Like many species with unpaired electrons (free radicals), atomic Cl is very reactive. The Cl atoms react with stratospheric ozone to produce an intermediate, chlorine monoxide ( $\mathrm{ClO} \cdot$ ), which then reacts with free O atoms to regenerate Cl atoms:

$$
\begin{aligned}
\mathrm{O}_{3}+\mathrm{Cl} \cdot & \longrightarrow \mathrm{ClO} \cdot+\mathrm{O}_{2} \\
\mathrm{ClO} \cdot+\mathrm{O} & \longrightarrow \mathrm{Cl} \cdot+\mathrm{O}_{2}
\end{aligned}
$$

The sum of these steps is the ozone breakdown reaction:

$$
\begin{gathered}
\mathrm{O}_{3}+\mathrm{Cl}+\mathrm{ClO}+\mathrm{O} \longrightarrow \mathrm{ClO}^{-}+\mathrm{O}_{2}+\mathrm{Cl} \cdot+\mathrm{O}_{2} \\
\text { or } \\
\mathrm{O}_{3}+\mathrm{O} \longrightarrow 2 \mathrm{O}_{2}
\end{gathered}
$$

Note that the Cl atom acts as a homogeneous catalyst: it exists in the same phase as the reactants, speeds up the process via a different mechanism, and is regenerated. The problem is that each Cl atom has a stratospheric half-life of about 2 years, during which time it speeds the breakdown of about 100,000 ozone molecules. Bromine is a more effective catalyst, but much less ends up in the stratosphere. Halons, used as fire suppressants, and methyl bromide, an agricultural insecticide, are the main anthropogenic (human-made) sources of stratospheric bromine.

In 1985, British scientists reported their decade-long observation of the development of an Antarctic ozone hole, the reduction of stratospheric ozone over the Antarctic region when the Sun rises after the long winter darkness. Later measurements of high [ $\mathrm{ClO} \cdot]$ over Antarctica are consistent with the breakdown mecha-

Figure B16.6 The increasing size of the Antarctic ozone hole. Satellite images show the large increase in the size of the "hole" in the ozone layer (indicated by the leftmost colors in the key) as a result of the large decrease in ozone concentration over the South Pole from September 1979 to September 2006. Since 1995, data show a similar thinning, though not yet as severe, over the North Pole.
nism. Expansion of the ozone hole as CFCs accumulated is shown in Figure B16.6. The ozone hole enlarges by heterogeneous catalysis involving polar stratospheric clouds. The clouds provide a
Fsurface for reaetions that convert inactive chlorine compounds, such as HCl and chlorine nitrate $\left(\mathrm{ClONO}_{2}\right)$, to substances, such as $\mathrm{Cl}_{2}$, that are cleaved by UV radiation to Cl atoms. Heterogeneous catalysis also occurs on fine particles in the stratosphere. Dust from the eruption of Mt. Pinatubo in 1991 reduced stratospheric ozone for 2 years. There is ozone thinning over the North Pole, and NASA has also documented the loss of stratospheric ozone at middle latitudes, such as over the United States. So far, both of these losses occur to a lower extent and at a lower rate.

The Montreal Protocol in 1987 and later amendments curtailed growth in production of CFCs and set dates for phasing out these and other chlorinated and brominated compounds, such as $\mathrm{CCl}_{4}, \mathrm{CCl}_{3} \mathrm{CH}_{3}$, and $\mathrm{CH}_{3} \mathrm{Br}$. Another change was replacement of CFC aerosol propellants by hydrocarbons, such as isobutane, $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CH}$. Replacement of CFCs in refrigeration units is more difficult, because it will require changes in equipment. The first replacements for CFCs were hydrochlorofluorocarbons (HCFCs), such as $\mathrm{CHF}_{2} \mathrm{Cl}$. These deplete ozone less than CFCs do because they have relatively short tropospheric lifetimes due to abstraction of H atoms by hydroxyl radicals $(\cdot \mathrm{OH})$ :

$$
\mathrm{CHF}_{2} \mathrm{Cl}+\cdot \mathrm{OH} \longrightarrow \mathrm{H}_{2} \mathrm{O}+\cdot \mathrm{CF}_{2} \mathrm{Cl}
$$

After this initial attack, further degradation occurs rapidly.
HCFCs will be phased out by 2040 and replaced by hydrofluorocarbons (HFCs, which contain only C, H, and F) in devices such as car air conditioners. HFCs are preferable to CFCs or HCFCs because fluorine is a poor catalyst of ozone breakdown. Nevertheless, because of the long lifetimes of CFCs and the ongoing emissions of HCFCs until their phase-out, full recovery of the ozone layer may take another century! The good news is that tropospheric halogen levels have already begun to fall.

## Section Summary

A catalyst is a substance that increases the rate of a reaction without being consumed. It accomplishes this by providing an alternative mechanism with a lower activation energy. - Homogeneous catalysts function in the same phase as the reactants. Heterogeneous catalysts act in a different phase from the reactants. - The hydrogenation of carbon-carbon double bonds takes place on a solid catalyst, which speeds the breakage of the $\mathrm{H}-\mathrm{H}$ bond in $\mathrm{H}_{2}$. - Enzymes are biological catalysts with spectacular efficiency and specificity. - Chlorine atoms derived from CFC molecules catalyze the breakdown of stratospheric ozone.

## Chapter Perspective

With this introduction to chemical kinetics, we have begun to explore the dynamic inner workings of chemical change. Variations in reaction rate are observed with concentration and temperature changes, which operate on the molecular level through the frequency and energetics of particle collisions and the details of reactant structure. Kinetics allows us to speculate about the molecular pathway of a reaction. Modern industry and biochemistry depend on its principles. However, speed and yield are very different aspects of a reaction. In Chapter 17, we'll see how opposing reaction rates give rise to the equilibrium state and examine how much product has formed once the net reaction stops.

CHAPTER REVIEW GUIDE The following sections provide many aids to help you study this chapter. (Numbers in parentheses refer to pages, unless noted otherwise.)

## Learning Objectives These are concepts and skills you should know after studying this chapter.

Relevant section and/or sample problem (SP) numbers appear in parentheses.

## Understand These Concepts

1. How reaction rate depends on concentration, physical state, and temperature (Section 16.1)
2. The meaning of reaction rate in terms of changing concentrations over time (Section 16.2)
3. How the rate can be expressed in terms of reactant or product concentrations (Section 16.2)
4. The distinction between average and instantaneous rate and why the instantaneous rate changes during the reaction (Section 16.2)
5. The interpretation of reaction rate in terms of reactant and product concentrations (Section 16.2)
6. The experimental basis of the rate law and the information needed to determine it-initial rate data, reaction orders, and rate constant (Section 16.3)
7. The importance of reaction order in determining the rate (Section 16.3)
8. How reaction order is determined from initial rates at different concentrations (Section 16.3)
9. How integrated rate laws show the dependence of concentration on time (Section 16.4)
10. What reaction half-life means and why it is constant for a first-order reaction (Section 16.4)
11. Activation energy and the effect of temperature on the rate constant (Arrhenius equation) (Section 16.5)
12. Why concentrations are multiplied in the rate law (Section 16.6)
13. How temperature affects rate by influencing collision energy and, thus, the fraction of collisions with energy exceeding the activation energy (Section 16.6)
14. Why molecular orientation and complexity influence the number of effective collisions and the rate (Section 16.6)
15. The transition state as the momentary species between reactants and products whose formation requires the activation energy (Section 16.6)
16. How an elementary step represents a single molecular event and its molecularity equals the number of colliding particles (Section 16.7)
17. How a reaction mechanism consists of several elementary steps, with the slowest step determining the overall rate (Section 16.7)
18. The criteria for a valid reaction mechanism (Section 16.7)
19. How a catalyst speeds a reaction by lowering the activation energy (Section 16.8)
20. The distinction between homogeneous and heterogeneous catalysis (Section 16.8)

## Master These Skills

1. Calculating instantaneous rate from the slope of a tangent to a concentration vs. time plot (Section 16.2)
2. Expressing reaction rate in terms of changes in concentration over time (SP 16.1)
3. Determining reaction order from a known rate law (SP 16.2)
4. Determining reaction order from changes in initial rate with concentration (SPs 16.3, 16.4)
5. Calculating the rate constant and its units (Section 16.3)
6. Using an integrated rate law to find concentration at a given time or the time to reach a given concentration (SP 16.5)
7. Determining reaction order graphically with a rearranged integrated rate law (Section 16.4)
8. Determining the half-life of a reaction (SPs 16.6, 16.7)
9. Using a form of the Arrhenius equation to calculate the activation energy (SP 16.8)

## Learning Objectives (continued)

10. Using reaction energy diagrams to depict the energy changes during a reaction (SP 16.9)
11. Postulating a transition state for a simple reaction (SP 16.9)
12. Determining the molecularity and rate law for an elementary step (SP 16.10)
13. Constructing a mechanism with either a slow or a fast initial step (Section 16.7)

Key Terms These important terms appear in boldface in the chapter and are defined again in the Glossary.
chemical kinetics (685)

Key Equations and Relationships Numbered and screened concepts are listed for you to refer to or memorize.
16.1 Expressing reaction rate in terms of reactant A (688):

$$
\text { Rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t}
$$

16.2 Expressing the rate of a general reationa00 PDE

$$
\begin{gathered}
a \mathrm{~A}+b \mathrm{~B} \longrightarrow c \mathrm{C}+d \mathrm{D} \\
\text { Rate }=-\frac{1}{a} \frac{\Delta[\mathrm{~A}]}{\Delta t}=-\frac{1}{b} \frac{\Delta[\mathrm{~B}]}{\Delta t}=\frac{1}{c} \frac{\Delta[\mathrm{C}]}{\Delta t}=\frac{1}{d} \frac{\Delta[\mathrm{D}]}{\Delta t}
\end{gathered}
$$

16.3 Writing a general rate law (in which products do not appear) (691):

$$
\text { Rate }=k[\mathrm{~A}]^{m}[\mathrm{~B}]^{n} \cdots
$$

16.4 Calculating the time to reach a given [A] in a first-order reaction (rate $=k[\mathrm{~A}])(700)$ :

$$
\ln \frac{[\mathrm{A}]_{0}}{[\mathrm{~A}]_{t}}=k t
$$

16.5 Calculating the time to reach a given $[\mathrm{A}]$ in a simple secondorder reaction (rate $\left.=k[\mathrm{~A}]^{2}\right)(700)$ :

$$
\frac{1}{[\mathrm{~A}]_{t}}-\frac{1}{[\mathrm{~A}]_{0}}=k t
$$

16.6 Calculating the time to reach a given $[\mathrm{A}]$ in a zero-order reaction (rate $=k$ ) (700):

$$
[\mathrm{A}]_{t}-[\mathrm{A}]_{0}=-k t
$$

E16.7Finding the hatl-life of a first-order process (702):

$$
t_{1 / 2}=\frac{\ln 2}{k}=\frac{0.693}{k}
$$

16.8 Relating the rate constant to the temperature (Arrhenius equation) (706):

$$
k=A e^{-E_{\mathrm{a}} / R T}
$$

16.9 Calculating the activation energy (rearranged form of Arrhenius equation) (706):

$$
\ln \frac{k_{2}}{k_{1}}=-\frac{E_{\mathrm{a}}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right)
$$

16.10 Relating the heat of reaction to the forward and reverse activation energies (713):

$$
\Delta H_{\mathrm{rxn}}=E_{\mathrm{a}(\mathrm{fwd})}-E_{\mathrm{a}(\mathrm{rev})}
$$

Highlighted Figures and Tables These figures (F) and tables (T) provide a visual review of key ideas.

F16.1 Reaction rate (685)
F16.5 Concentration of $\mathrm{O}_{3}$ vs. time during reaction with $\mathrm{C}_{2} \mathrm{H}_{4}$ (689)

T16.3 Units of $k$ for overall reaction orders (699)
F16.7 Integrated rate laws and reaction orders (701)
F16.8 Graphical determination of reaction order (702)
F16.9 $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ vs. time for three half-lives (703)
T16.4 Zero-order, first-order, and simple second-order reactions (705)

F16.10 Dependence of the rate constant on temperature (705)

F16.15 Energy-level diagram for a reaction (709)
F16.16 Fraction of collisions with energy exceeding $E_{\mathrm{a}}$ (710)
F16.19 Reaction energy diagram for the reaction of $\mathrm{CH}_{3} \mathrm{Br}$ and $\mathrm{OH}^{-}$(712)
T16.6 Rate laws for general elementary steps (715)
F16.22 Reaction energy diagram for catalyzed and uncatalyzed processes (720)

Brief Solutions to FOLLOW-UP PROBLEMS Compare your solutions to these calculation steps and answers.

$$
\begin{aligned}
& 16.1(\mathrm{a}) 4 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{~N}_{2} \mathrm{O}_{3}(g) ; \\
& \text { rate }=-\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}=-\frac{1}{4} \frac{\Delta[\mathrm{NO}]}{\Delta t}=\frac{1}{2} \frac{\Delta\left[\mathrm{~N}_{2} \mathrm{O}_{3}\right]}{\Delta t} \\
& \text { (b) } \begin{aligned}
&-\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}=-\frac{1}{4} \frac{\Delta[\mathrm{NO}]}{\Delta t} \\
& \quad=-\frac{1}{4}\left(-1.60 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}\right)=4.00 \times 10^{-5} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}
\end{aligned}
\end{aligned}
$$

16.2 First order in $\mathrm{Br}^{-}$, first order in $\mathrm{BrO}_{3}{ }^{-}$, second order in $\mathrm{H}^{+}$, fourth order overall
16.3 Rate $=k\left[\mathrm{H}_{2}\right]^{m}\left[\mathrm{I}_{2}\right]^{n}$. From experiments 1 and $3, m=1$. From experiments 2 and $4, n=1$.
Therefore, rate $=k\left[\mathrm{H}_{2}\right]\left[\mathrm{I}_{2}\right]$; second order overall.
16.4 (a) The rate law shows the reaction is zero order in Y , so the rate is not affected by doubling Y:
rate of Expt $2=0.25 \times 10^{-5} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$
(b) The rate of Expt 3 is four times that of Expt 1 , so $[\mathrm{X}]$ doubles.

$16.51 /[\mathrm{HI}]_{1}-1 /[\mathrm{HI}]_{0}=k t$;
$111 \mathrm{~L} / \mathrm{mol}-100 \mathrm{~L} / \mathrm{mol}=\left(2.4 \times 10^{-21} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}\right)(t)$
$t=4.6 \times 10^{21} \mathrm{~s}\left(\right.$ or $\left.1.5 \times 10^{14} \mathrm{yr}\right)$
16.6 By inspection, we see that one-quarter of the original number remain after 6.0 min , so one-half remain after 3.0 min : $t_{1 / 2}=3.0 \mathrm{~min}$; $k=0.693 / 3.0 \mathrm{~min}=0.23 \mathrm{~min}^{-1}$
$16.7 t_{1 / 2}=(\ln 2) / k ; k=0.693 / 13.1 \mathrm{~h}=5.29 \times 10^{-2} \mathrm{~h}^{-1}$
$16.8 \ln \frac{0.286 \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}}{k_{1}}=-\frac{1.00 \times 10^{5} \mathrm{~J} / \mathrm{mol}}{8.314 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{K}}$

$$
\begin{aligned}
& \times\left(\frac{1}{500 . \mathrm{K}}-\frac{1}{490 . \mathrm{K}}\right) \\
= & 0.491 \\
k_{1}= & 0.175 \mathrm{~L} / \mathrm{mol} \cdot \mathrm{~s}
\end{aligned}
$$

16.9

16.10 (a) Balanced equation:
$2 \mathrm{NO}(g)+2 \mathrm{H}_{2}(g) \longrightarrow \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)$
(b) Step 2 is unimolecular. All others are bimolecular.
(c) Rate $_{1}=k_{1}[\mathrm{NO}]^{2}$; rate $_{2}=k_{2}\left[\mathrm{H}_{2}\right]$; rate $_{3}=k_{3}\left[\mathrm{~N}_{2} \mathrm{O}_{2}\right][\mathrm{H}]$; $\operatorname{rate}_{4}=k_{4}[\mathrm{HO}][\mathrm{H}] ;$ rate $_{5}=k_{5}[\mathrm{H}]\left[\mathrm{N}_{2} \mathrm{O}\right]$.

## PROBLEMS

Problems with colored numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and provide the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

## Factors That Influence Reaction Rate

## - Concept Review Questions

16.1 What variable of a chemical reaction is measured over time to obtain the reaction rate?
16.2 How does an increase in pressure affect the rate of a gasphase reaction? Explain.
16.3 A reaction is carried out with water as the solvent. How does the addition of more water to the reaction vessel affect the rate of the reaction? Explain.
16.4 A gas reacts with a solid that is present in large chunks. Then the reaction is run again with the solid pulverized. How does the increase in the surface area of the solid affect the rate of its reaction with the gas? Explain.
16.5 How does an increase in temperature affect the rate of a reaction? Explain the two factors involved.
16.6 In a kinetics experiment, a chemist places crystals of iodine in a closed reaction vessel, introduces a given quantity of hydrogen gas, and obtains data to calculate the rate of hydrogen iodide formation. In a second experiment, she uses the same amounts of iodine and hydrogen, but first warms the flask to $130^{\circ} \mathrm{C}$, a temperature above the sublimation point of iodine. In which of these experiments does the reaction proceed at a higher rate? Explain.

## Expressing the Reaction Rate

(Sample Problem 16.1)

## Concept Review Questions

16.7 Define reaction rate. Assuming constant temperature and a closed reaction vessel, why does the rate change with time?
16.8 (a) What is the difference between an average rate and an instantaneous rate? (b) What is the difference between an initial rate and an instantaneous rate?
16.9 Give two reasons to measure initial rates in a kinetics study. 16.10 For the reaction $\mathrm{A}(g) \longrightarrow \mathrm{B}(g)$, sketch two curves on the same set of axes that show
(a) The formation of product as a function of time
(b) The consumption of reactant as a function of time
16.11 For the reaction $\mathrm{C}(g) \longrightarrow \mathrm{D}(g)$, [C] vs. time is plotted:

How do you determine each of the following?
(a) The average rate over the entire experiment
(b) The reaction rate at time $x$
(c) The initial reaction rate
(d) Would the values in parts (a), (b), and (c) be different if you plotted [D] vs. time? Explain.

## Skill-Building Exercises (grouped in similar pairs)

16.12 The compound $\mathrm{AX}_{2}$ decomposes according to the equation $2 \mathrm{AX}_{2}(g) \longrightarrow 2 \mathrm{AX}(g)+\mathrm{X}_{2}(g)$. In one experiment, $\left[\mathrm{AX}_{2}\right]$ was measured at various times and these data were obtained:

| Time (s) | $\left[\mathrm{AX}_{2}\right](\mathrm{mol} / \mathrm{L})$ |  |
| :---: | :---: | :---: |
| 0.0 | 0.0500 |  |
| 2.0 | 0.0448 |  |
| 6.0 | 0.0300 |  |
| 8.0 | 0.0249 |  |
| 10.0 | 0.0209 |  |
| 20.0 | 0.0088 O2go |  |
|  |  | PDF |

(a) Find the average rate over the entire experiment.
(b) Is the initial rate higher or lower than the rate in part (a)?

Use graphical methods to estimate the initial rate.
16.13 (a) Use the data from Problem 16.12 to calculate the average rate from 8.0 to 20.0 s .
(b) Is the rate at exactly 5.0 s higher or lower than the rate in part (a)? Use graphical methods to estimate the rate at 5.0 s .
16.14 Express the rate of reaction in terms of the change in concentration of each of the reactants and products:

$$
2 \mathrm{~A}(g) \longrightarrow \mathrm{B}(g)+\mathrm{C}(g)
$$

When $[\mathrm{C}]$ is increasing at $2 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$, how fast is $[\mathrm{A}]$ decreasing?
16.15 Express the rate of reaction in terms of the change in concentration of each of the reactants and products:

$$
\mathrm{D}(g) \longrightarrow \frac{3}{2} \mathrm{E}(g)+\frac{5}{2} \mathrm{~F}(g)
$$

When $[\mathrm{E}]$ is increasing at $0.25 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$, how fast is $[\mathrm{F}]$ increasing?
16.16 Express the rate of reaction in terms of the change in concentration of each of the reactants and products:

$$
\mathrm{A}(g)+2 \mathrm{~B}(g) \longrightarrow \mathrm{C}(g)
$$

When $[\mathrm{B}]$ is decreasing at $0.5 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$, how fast is $[\mathrm{A}]$ decreasing? 16.17 Express the rate of reaction in terms of the change in concentration of each of the reactants and products:

$$
2 \mathrm{D}(g)+3 \mathrm{E}(g)+\mathrm{F}(g) \longrightarrow 2 \mathrm{G}(g)+\mathrm{H}(g)
$$

When [D] is decreasing at $0.1 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$, how fast is $[\mathrm{H}]$ increasing?
16.18 Reaction rate is expressed in terms of changes in concentration of reactants and products. Write a balanced equation for

$$
\text { Rate }=-\frac{1}{2} \frac{\Delta\left[\mathrm{~N}_{2} \mathrm{O}_{5}\right]}{\Delta t}=\frac{1}{4} \frac{\Delta\left[\mathrm{NO}_{2}\right]}{\Delta t}=\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}
$$

16.19 Reaction rate is expressed in terms of changes in concentration of reactants and products. Write a balanced equation for

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{CH}_{4}\right]}{\Delta t}=-\frac{1}{2} \frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}=\frac{1}{2} \frac{\Delta\left[\mathrm{H}_{2} \mathrm{O}\right]}{\Delta t}=\frac{\Delta\left[\mathrm{CO}_{2}\right]}{\Delta t}
$$

## - Problems in Context

16.20 The decomposition of NOBr is studied manometrically because the number of moles of gas changes; it cannot be studied colorimetrically because both NOBr and $\mathrm{Br}_{2}$ are reddish brown:

$$
2 \mathrm{NOBr}(g) \longrightarrow 2 \mathrm{NO}(g)+\mathrm{Br}_{2}(g)
$$

Use the data below to answer the following:
(a) Determine the average rate over the entire experiment.
(b) Determine the average rate between 2.00 and 4.00 s .
(c) Use graphical methods to estimate the initial reaction rate.
(d) Use graphical methods to estimate the rate at 7.00 s .
(e) At what time does the instantaneous rate equal the average rate over the entire experiment?

| Time (s) | $[\mathrm{NOBr}](\mathrm{mol} / \mathrm{L})$ |
| :---: | :---: |
| 0.00 | 0.0100 |
| 2.00 | 0.0071 |
| 4.00 | 0.0055 |
| 6.00 | 0.0045 |
| 8.00 | 0.0038 |
| 10.00 | 0.0033 |

16.21 The formation of ammonia is one of the most important processes in the chemical industry:

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g)
$$

Frexpesstheyent terms of changes in [ $\left.\mathrm{N}_{2}\right],\left[\mathrm{H}_{2}\right]$, and $\left[\mathrm{NH}_{3}\right]$. 16.22 Although the depletion of stratospheric ozone threatens life on Earth today, its accumulation was one of the crucial processes that allowed life to develop in prehistoric times:

$$
3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{O}_{3}(\mathrm{~g})
$$

(a) Express the reaction rate in terms of $\left[\mathrm{O}_{2}\right]$ and $\left[\mathrm{O}_{3}\right]$.
(b) At a given instant, the reaction rate in terms of $\left[\mathrm{O}_{2}\right]$ is $2.17 \times 10^{-5} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$. What is it in terms of $\left[\mathrm{O}_{3}\right]$ ?

## The Rate Law and Its Components

(Sample Problems 16.2 to 16.4)

## - Concept Review Questions

16.23 The rate law for the general reaction

$$
a \mathrm{~A}+b \mathrm{~B}+\cdots \longrightarrow c \mathrm{C}+d \mathrm{D}+\cdots
$$

is rate $=k[\mathrm{~A}]^{m}[\mathrm{~B}]^{n} \cdots$.
(a) Explain the meaning of $k$. (b) Explain the meanings of $m$ and $n$. Does $m=a$ and $n=b$ ? Explain. (c) If the reaction is first order in A and second order in B , and time is measured in minutes (min), what are the units for $k$ ?
16.24 You are studying the reaction

$$
\mathrm{A}_{2}(g)+\mathrm{B}_{2}(g) \longrightarrow 2 \mathrm{AB}(g)
$$

to determine its rate law. Assuming that you have a valid experimental procedure for obtaining $\left[\mathrm{A}_{2}\right]$ and $\left[\mathrm{B}_{2}\right]$ at various times, explain how you determine (a) the initial rate, (b) the reaction orders, and (c) the rate constant.
16.25 By what factor does the rate change in each of the following cases (assuming constant temperature)?
(a) A reaction is first order in reactant A , and $[\mathrm{A}]$ is doubled.
(b) A reaction is second order in reactant B , and $[\mathrm{B}]$ is halved.
(c) A reaction is second order in reactant C , and $[\mathrm{C}]$ is tripled.

## Skill-Building Exercises (grouped in similar pairs)

16.26 Give the individual reaction orders for all substances and the overall reaction order from the following rate law:

$$
\text { Rate }=k\left[\mathrm{BrO}_{3}^{-}\right]\left[\mathrm{Br}^{-}\right]\left[\mathrm{H}^{+}\right]^{2}
$$

16.27 Give the individual reaction orders for all substances and the overall reaction order from the following rate law:

$$
\text { Rate }=k \frac{\left[\mathrm{O}_{3}\right]^{2}}{\left[\mathrm{O}_{2}\right]}
$$

16.28 By what factor does the rate in Problem 16.26 change if each of the following changes occurs: (a) $\left[\mathrm{BrO}_{3}{ }^{-}\right]$is doubled; (b) $\left[\mathrm{Br}^{-}\right]$is halved; (c) $\left[\mathrm{H}^{+}\right]$is quadrupled?
16.29 By what factor does the rate in Problem 16.27 change if each of the following changes occurs: (a) $\left[\mathrm{O}_{3}\right]$ is doubled; (b) $\left[\mathrm{O}_{2}\right]$ is doubled; (c) $\left[\mathrm{O}_{2}\right]$ is halved?
16.30 Give the individual reaction orders for all substances and the overall reaction order from this rate law:

$$
\text { Rate }=k\left[\mathrm{NO}_{2}\right]^{2}\left[\mathrm{Cl}_{2}\right]
$$

16.31 Give the individual reaction orders for all substances and the overall reaction order from this rate law:

$$
\text { Rate }=k \frac{\left[\mathrm{HNO}_{2}\right]^{4}}{[\mathrm{NO}]^{2}}
$$

16.32 By what factor does the rate in Problem 16.30 change if each of the following changes occurs: (a) $\left[\mathrm{NO}_{2}\right]$ is tripled; (b) $\left[\mathrm{NO}_{2}\right]$ and $\left[\mathrm{Cl}_{2}\right]$ are doubled; (c) $\left[\mathrm{Cl}_{2}\right]$ is halved?
16.33 By what factor does the rate in Problem 16.31 change if each of the following changes occurs: (a) $\left[\mathrm{HNO}_{2}\right]$ is doubled; (b) $[\mathrm{NO}]$ is doubled; (c) $\left[\mathrm{HNO}_{2}\right]$ is halved? AO OO PDE
16.34 For the reaction

$$
4 \mathrm{~A}(g)+3 \mathrm{~B}(g) \longrightarrow 2 \mathrm{C}(g)
$$

the following data were obtained at constant temperature:

| Experiment | Initial [A] <br> $(\mathrm{mol} / \mathrm{L})$ | Initial [B] <br> $(\mathrm{mol} / \mathrm{L})$ | Initial Rate <br> $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{min})$ |
| :---: | :---: | :---: | :---: |
| 1 | 0.100 | 0.100 | 5.00 |
| 2 | 0.300 | 0.100 | 45.0 |
| 3 | 0.100 | 0.200 | 10.0 |
| 4 | 0.300 | 0.200 | 90.0 |

(a) What is the order with respect to each reactant? (b) Write the rate law. (c) Calculate $k$ (using the data from experiment 1).
16.35 For the reaction

$$
\mathrm{A}(g)+\mathrm{B}(g)+\mathrm{C}(g) \longrightarrow \mathrm{D}(g)
$$

the following data were obtained at constant temperature:

| Expt | Initial [A] <br> $(\mathrm{mol} / \mathrm{L})$ | Initial [B] <br> $(\mathrm{mol} / \mathrm{L})$ | Initial [C] <br> $(\mathrm{mol} / \mathrm{L})$ | Initial Rate <br> $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 0.0500 | 0.0500 | 0.0100 | $6.25 \times 10^{-3}$ |
| 2 | 0.1000 | 0.0500 | 0.0100 | $1.25 \times 10^{-2}$ |
| 3 | 0.1000 | 0.1000 | 0.0100 | $5.00 \times 10^{-2}$ |
| 4 | 0.0500 | 0.0500 | 0.0200 | $6.25 \times 10^{-3}$ |

(a) What is the order with respect to each reactant? (b) Write the rate law. (c) Calculate $k$ (using the data from experiment 1).
16.36 Without consulting Table 16.3, give the units of the rate constants for reactions with the following overall orders: (a) first order; (b) second order; (c) third order; (d) $\frac{5}{2}$ order.
16.37 Give the overall reaction order that corresponds to a rate constant with each of the following units: (a) $\mathrm{mol} / \mathrm{L} \cdot \mathrm{s}$; (b) $\mathrm{yr}^{-1}$; (c) $(\mathrm{mol} / \mathrm{L})^{1 / 2} \cdot \mathrm{~s}^{-1}$; (d) $(\mathrm{mol} / \mathrm{L})^{-5 / 2} \cdot \mathrm{~min}^{-1}$.

## - Problems in Context

16.38 Phosgene is a toxic gas prepared by the reaction of carbon monoxide with chlorine:

$$
\mathrm{CO}(g)+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{COCl}_{2}(g)
$$

These data were obtained in a kinetics study of its formation:

| Experiment | Initial [CO] <br> $(\mathbf{m o l} / \mathrm{L})$ | Initial $\left[\mathrm{Cl}_{2}\right]$ <br> $(\mathrm{mol} / \mathrm{L})$ | Initial Rate <br> $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ |
| :---: | :---: | :---: | :---: |
| 1 | 1.00 | 0.100 | $1.29 \times 10^{-29}$ |
| 2 | 0.100 | 0.100 | $1.33 \times 10^{-30}$ |
| 3 | 0.100 | 1.00 | $1.30 \times 10^{-29}$ |
| 4 | 0.100 | 0.0100 | $1.32 \times 10^{-31}$ |

(a) Write the rate law for the formation of phosgene.
(b) Calculate the average value of the rate constant.

## Integrated Rate Laws: Concentration Changes over Time

 (Sample Problems 16.5 to 16.7)
## - Concept Review Questions

16.39 How are integrated rate laws used to determine reaction order? What is the order in reactant if a plot of
(a) The natural logarithm of [reactant] vs. time is linear?
(b) The inverse of [reactant] vs. time is linear?
(c) [Reactant] vs. time is linear?
16.40 Define the half-life of a reaction. Explain on the molecular level why the half-life of a first-order reaction is constant.

- Skitl-Buitding Exercises (grouped in similar pairs)
16.41 For the simple decomposition reaction

$$
\mathrm{AB}(g) \longrightarrow \mathrm{A}(g)+\mathrm{B}(g)
$$

rate $=k[\mathrm{AB}]^{2}$ and $k=0.2 \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$. How long will it take for $[\mathrm{AB}]$ to reach one-third of its initial concentration of 1.50 M ? 16.42 For the reaction in Problem 16.41, what is [AB] after 10.0 s ?
16.43 In a first-order decomposition reaction, $50.0 \%$ of a compound decomposes in 10.5 min . (a) What is the rate constant of the reaction? (b) How long does it take for $75.0 \%$ of the compound to decompose?
16.44 A decomposition reaction has a rate constant of $0.0012 \mathrm{yr}^{-1}$. (a) What is the half-life of the reaction? (b) How long does it take for [reactant] to reach $12.5 \%$ of its original value?

## - Problems in Context

16.45 In a study of ammonia production, an industrial chemist discovers that the compound decomposes to its elements $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ in a first-order process. She collects the following data:

| Time (s) | 0 | 1.000 | 2.000 |
| :--- | :--- | :--- | :--- |
| $\left[\mathrm{NH}_{3}\right](\mathrm{mol} / \mathrm{L})$ | 4.000 | 3.986 | 3.974 |

(a) Use graphical methods to determine the rate constant.
(b) What is the half-life for ammonia decomposition?

The Effect of Temperature on Reaction Rate
(Sample Problem 16.8)

## - Concept Review Questions

16.46 Use the exponential term in the Arrhenius equation to explain how temperature affects reaction rate.
16.47 How is the activation energy determined from the Arrhenius equation?
16.48 (a) Graph the relationship between $k$ ( $y$ axis) and $T$ ( $x$ axis). (b) Graph the relationship between $\ln k$ ( $y$ axis) and $1 / T$ ( $x$ axis). How is the activation energy determined from this graph?

## - Skill-Building Exercises (grouped in similar pairs)

16.49 The rate constant of a reaction is $4.7 \times 10^{-3} \mathrm{~s}^{-1}$ at $25^{\circ} \mathrm{C}$, and the activation energy is $33.6 \mathrm{~kJ} / \mathrm{mol}$. What is $k$ at $75^{\circ} \mathrm{C}$ ?
16.50 The rate constant of a reaction is $4.50 \times 10^{-5} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$ at $195^{\circ} \mathrm{C}$ and $3.20 \times 10^{-3} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$ at $258^{\circ} \mathrm{C}$. What is the activation energy of the reaction?

## - Problems in Context

16.51 Understanding the high-temperature formation and breakdown of the nitrogen oxides is essential for controlling the pollutants generated from power plants and cars. The first-order breakdown of dinitrogen monoxide to its elements has rate constants of $0.76 / \mathrm{s}$ at $727^{\circ} \mathrm{C}$ and $0.87 / \mathrm{s}$ at $757^{\circ} \mathrm{C}$. What is the activation energy of this reaction?

## Explaining the Effects of Concentration and Temperature (Sample Problem 16.9)

## Concept Review Questions

16.52 What is the central idea of collision theory? How does this idea explain the effect of concentration on reaction rate?
16.53 Is collision frequency the only factor affecting rate? Explain. 16.54 Arrhenius proposed that each reaction has an energy threshold that must be reached for the particles to react. The kinetic theory of gases proposes that the average kinetic energy of the particles is proportional to the absolute temperature. How do these concepts relate to the effect of temperatore Rate?
16.55 (a) For a reaction with a given $E_{\mathrm{a}}$, how does an increase in $T$ affect the rate? (b) For a reaction at a given $T$, how does a decrease in $E_{\mathrm{a}}$ affect the rate?
16.56 In the reaction $\mathrm{AB}+\mathrm{CD} \rightleftharpoons \mathrm{EF}, 4 \times 10^{-5} \mathrm{~mol}$ of AB molecules collide with $4 \times 10^{-5} \mathrm{~mol}$ of CD molecules. Will $4 \times 10^{-5} \mathrm{~mol}$ of EF form? Explain.
16.57 Assuming the activation energies are equal, which of the following reactions will occur at a higher rate at $50^{\circ} \mathrm{C}$ ? Explain.

$$
\begin{aligned}
\mathrm{NH}_{3}(g)+\mathrm{HCl}(g) & \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}(s) \\
\mathrm{N}\left(\mathrm{CH}_{3}\right)_{3}(g)+\mathrm{HCl}(g) & \longrightarrow\left(\mathrm{CH}_{3}\right)_{3} \mathrm{NHCl}(s)
\end{aligned}
$$

Skill-Building Exercises (grouped in similar pairs)
16.58 For the reaction $\mathrm{A}(g)+\mathrm{B}(g) \longrightarrow \mathrm{AB}(g)$, how many unique collisions between $A$ and $B$ are possible if there are four particles of A and three particles of B present in the vessel?
16.59 For the reaction $\mathrm{A}(g)+\mathrm{B}(g) \longrightarrow \mathrm{AB}(g)$, how many unique collisions between A and B are possible if 1.01 mol of $\mathrm{A}(g)$ and 2.12 mol of $\mathrm{B}(g)$ are present in the vessel?
16.60 At $25^{\circ} \mathrm{C}$, what is the fraction of collisions with energy equal to or greater than an activation energy of $100 . \mathrm{kJ} / \mathrm{mol}$ ?
16.61 If the temperature in Problem 16.60 is increased to $50 .{ }^{\circ} \mathrm{C}$, by what factor does the fraction of collisions with energy equal to or greater than the activation energy change?
16.62 For the reaction $\mathrm{ABC}+\mathrm{D} \rightleftharpoons \mathrm{AB}+\mathrm{CD}, \Delta H_{\mathrm{rxn}}^{\circ}=$ $-55 \mathrm{~kJ} / \mathrm{mol}$ and $E_{\mathrm{a}(\mathrm{fwd})}=215 \mathrm{~kJ} / \mathrm{mol}$. Assuming a one-step reaction, (a) draw a reaction energy diagram; (b) calculate $E_{\text {a(rev) }}$; and (c) sketch a possible transition state if ABC is V-shaped.
16.63 For the reaction $\mathrm{A}_{2}+\mathrm{B}_{2} \longrightarrow 2 \mathrm{AB}, E_{\mathrm{a}(\mathrm{fwd})}=125 \mathrm{~kJ} / \mathrm{mol}$ and $E_{\mathrm{a}(\mathrm{rev})}=85 \mathrm{~kJ} / \mathrm{mol}$. Assuming the reaction occurs in one
step, (a) draw a reaction energy diagram; (b) calculate $\Delta H_{\mathrm{rxn}}^{\circ}$; and (c) sketch a possible transition state.

## - Problems in Context

16.64 Aqua regia, a mixture of HCl and $\mathrm{HNO}_{3}$, has been used since alchemical times to dissolve many metals, including gold. Its orange color is due to the presence of nitrosyl chloride. Consider this one-step reaction for the formation of this compound: $\mathrm{NO}(g)+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{NOCl}(g)+\mathrm{Cl}(g) \quad \Delta H^{\circ}=83 \mathrm{~kJ}$
(a) Draw a reaction energy diagram, given $E_{\mathrm{a}(\mathrm{fwd})}$ is $86 \mathrm{~kJ} / \mathrm{mol}$.
(b) Calculate $E_{\mathrm{a}(\text { rev })}$.
(c) Sketch a possible transition state for the reaction. (Note: The atom sequence of nitrosyl chloride is $\mathrm{Cl}-\mathrm{N}-\mathrm{O}$.)

## Reaction Mechanisms: Steps in the Overall Reaction <br> (Sample Problem 16.10)

## Concept Review Questions

16.65 Is the rate of an overall reaction lower, higher, or equal to the average rate of the individual steps? Explain.
16.66 Explain why the coefficients of an elementary step equal the reaction orders of its rate law but those of an overall reaction do not.
16.67 Is it possible for more than one mechanism to be consistent with the rate law of a given reaction? Explain.
16.68 What is the difference between a reaction intermediate and a transition state?
16.69 Why is a bimolecular step more reasonable physically than a termolecular step?
16.70 If a slow step precedes a fast step in a two-step mechanism, do the substances in the fast step appear in the rate law? Explain. 16.71 If a fast step precedes a slow step in a two-step mechanism, how is the fast step affected? How is this effect used to determine the validity of the mechanism?

## Skill-Building Exercises (grouped in similar pairs)

16.72 The proposed mechanism for a reaction is
(1) $\mathrm{A}(g)+\mathrm{B}(g) \rightleftharpoons \mathrm{X}(g) \quad$ [fast]
(2) $\mathrm{X}(g)+\mathrm{C}(g) \longrightarrow \mathrm{Y}(g) \quad$ [slow]
(3) $\mathrm{Y}(g) \longrightarrow \mathrm{D}(g) \quad$ [fast]
(a) What is the overall equation?
(b) Identify the intermediate(s), if any.
(c) What are the molecularity and the rate law for each step?
(d) Is the mechanism consistent with the actual rate law: rate $=k[\mathrm{~A}][\mathrm{B}][\mathrm{C}]$ ?
(e) Is the following one-step mechanism equally valid: $\mathrm{A}(g)+\mathrm{B}(g)+\mathrm{C}(g) \longrightarrow \mathrm{D}(g)$ ?
16.73 Consider the following mechanism:
(1) $\mathrm{ClO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HClO}(a q)+\mathrm{OH}^{-}(a q)$ [fast]
(2) $\mathrm{I}^{-}(a q)+\mathrm{HClO}(a q) \longrightarrow \mathrm{HIO}(a q)+\mathrm{Cl}^{-}(a q) \quad$ [slow]
(3) $\mathrm{OH}^{-}(a q)+\mathrm{HIO}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{IO}^{-}(a q) \quad$ [fast]
(a) What is the overall equation?
(b) Identify the intermediate(s), if any.
(c) What are the molecularity and the rate law for each step?
(d) Is the mechanism consistent with the actual rate law: rate $=k\left[\mathrm{ClO}^{-}\right]\left[\mathrm{I}^{-}\right]$?

## - Problems in Context

16.74 In a study of nitrosyl halides, a chemist proposes the following mechanism for the synthesis of nitrosyl bromide:

$$
\begin{gathered}
\mathrm{NO}(g)+\mathrm{Br}_{2}(g) \rightleftharpoons \mathrm{NOBr}_{2}(g)[\text { [fast }] \\
\mathrm{NOBr}_{2}(g)+\mathrm{NO}(g)
\end{gathered} 2 \mathrm{NOBr}^{(g)}[\text { [slow] }]
$$

If the rate law is rate $=k\left[\mathrm{NO}^{2}\left[\mathrm{Br}_{2}\right]\right.$, is the proposed mechanism valid? If so, show that it satisfies the three criteria for validity.
16.75 The rate law for $2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)$ is rate $=k[\mathrm{NO}]^{2}\left[\mathrm{O}_{2}\right]$. In addition to the mechanism in the text (p. 719), the following ones have been proposed:

I $2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)$
II $2 \mathrm{NO}(g) \rightleftharpoons \mathrm{N}_{2} \mathrm{O}_{2}(g)$ [fast] $\mathrm{N}_{2} \mathrm{O}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g) \quad$ [slow]
III $2 \mathrm{NO}(g) \rightleftharpoons \mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \quad$ [fast] $\mathrm{N}_{2}(g)+2 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g) \quad$ [slow]
(a) Which of these mechanisms is consistent with the rate law?
(b) Which of these mechanisms is most reasonable? Why?

## Catalysis: Speeding Up a Chemical Reaction

## - Concept Review Questions

16.76 Consider the reaction $\mathrm{N}_{2} \mathrm{O}(g) \xrightarrow{\mathrm{Au}} \mathrm{N}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g)$.
(a) Is the gold a homogeneous or a heterogeneous catalyst?
(b) On the same set of axes, sketch the reaction energy diagrams for the catalyzed and the uncatalyzed reaction.
16.77 Does a catalyst increase reaction rate by the same means as a rise in temperature does? Explain.
16.78 In a classroom demonstration, hydrogen gas and oxygen gas are mixed in a balloon. The mixture is stable under normal conditions, but if a spark is applied to it or some powdered metal is added, the mixture explodes. (a) Is the spark acting as a catalyst? Explain. (b) Is the metal acting as a catalyst? Explain.
16.79 A principle of green chemistry is that the energy needs of industrial processes should have minimal enyironmental impaet. DE
How can the use of catalysts lead to "greenertechmologies?

## Comprehensive Problems

16.80 Experiments show that each of the following redox reactions is second order overall:
Reaction 1: $\mathrm{NO}_{2}(g)+\mathrm{CO}(g) \longrightarrow \mathrm{NO}(g)+\mathrm{CO}_{2}(g)$
Reaction 2: $\mathrm{NO}(g)+\mathrm{O}_{3}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)$
(a) When $\left[\mathrm{NO}_{2}\right]$ in reaction 1 is doubled, the rate quadruples. Write the rate law for this reaction.
(b) When [NO] in reaction 2 is doubled, the rate doubles. Write the rate law for this reaction.
(c) In each reaction, the initial concentrations of the reactants are equal. For each reaction, what is the ratio of the initial rate to the rate when the reaction is $50 \%$ complete?
(d) In reaction 1, the initial $\left[\mathrm{NO}_{2}\right]$ is twice the initial [CO]. What is the ratio of the initial rate to the rate at $50 \%$ completion? (e) In reaction 2, the initial [ NO$]$ is twice the initial $\left[\mathrm{O}_{3}\right]$. What is the ratio of the initial rate to the rate at $50 \%$ completion?
16.81 Consider the following reaction energy diagram:

(a) How many elementary steps are in the reaction mechanism?
(b) Which step is rate limiting?
(c) Is the overall reaction exothermic or endothermic?
16.82 Reactions between certain organic (alkyl) halides and water produce alcohols. Consider the overall reaction for $t$ butyl bromide (2-bromo-2-methylpropane):

$$
\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr}(a q)+\underset{\left(\mathrm{CH}_{3}\right)_{3} \mathrm{COH}(a q)}{\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}^{+}(a q)+\operatorname{Br}^{-}(a q)}
$$

The experimental rate law is rate $=k\left[\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr}\right]$. The accepted mechanism for the reaction is
(1) $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}-\mathrm{Br}(a q) \longrightarrow\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}^{+}(a q)+\mathrm{Br}^{-}(a q) \quad$ [slow]
(2) $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}-\mathrm{OH}_{2}{ }^{+}(a q)$ [fast]
(3) $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}-\mathrm{OH}_{2}{ }^{+}(a q) \longrightarrow \mathrm{H}^{+}(a q)+\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}-\mathrm{OH}(a q)$
[fast]
(a) Why doesn't $\mathrm{H}_{2} \mathrm{O}$ appear in the rate law?
(b) Write rate laws for the elementary steps.
(c) What reaction intermediates appear in the mechanism?
(d) Show that the mechanism is consistent with the experimental rate law.
16.83 The catalytic destruction of ozone occurs via a two-step mechanism, where X can be any of several species:
(1) $\mathrm{X}+\mathrm{O}_{3} \longrightarrow \mathrm{XO}+\mathrm{O}_{2} \quad[$ slow]
(2) $\mathrm{XO}+\mathrm{O} \longrightarrow \mathrm{X}+\mathrm{O}_{2} \quad$ [fast]
(a) Write the overall reaction.
(b) Write the rate law for each step.
(c) X acts as $\qquad$ , and XO acts as $\qquad$ _.
(d) High-flying aircraft release NO into the stratosphere, which catalyzes this process. When $\mathrm{O}_{3}$ and NO concentrations are $5 \times 40^{\text {² }}$ melecute/em ${ }^{5}$ and $1.0 \times 10^{9}$ molecule $/ \mathrm{cm}^{3}$, respectively, what is the rate of $\mathrm{O}_{3}$ depletion ( $k$ for the rate-determining step is $6 \times 10^{-15} \mathrm{~cm}^{3} /$ molecule $\left.\cdot \mathrm{s}\right)$ ?
16.84 Archeologists can determine the age of artifacts made of wood or bone by measuring the amount of the radioactive isotope ${ }^{14} \mathrm{C}$ present in the object. The amount of isotope decreases in a first-order process. If $15.5 \%$ of the original amount of ${ }^{14} \mathrm{C}$ is present in a wooden tool at the time of analysis, what is the age of the tool? The half-life of ${ }^{14} \mathrm{C}$ is 5730 yr .
16.85 A slightly bruised apple will rot extensively in about 4 days at room temperature $\left(20^{\circ} \mathrm{C}\right)$. If it is kept in the refrigerator at $0^{\circ} \mathrm{C}$, the same extent of rotting takes about 16 days. What is the activation energy for the rotting reaction?
16.86 Benzoyl peroxide, the substance most widely used against acne, has a half-life of $9.8 \times 10^{3}$ days when refrigerated. How long will it take to lose $5 \%$ of its potency ( $95 \%$ remaining)?
16.87 The rate law for the reaction

$$
\mathrm{NO}_{2}(g)+\mathrm{CO}(g) \longrightarrow \mathrm{NO}(g)+\mathrm{CO}_{2}(g)
$$

is rate $=k\left[\mathrm{NO}_{2}\right]^{2}$; one possible mechanism is shown on p. 717 . (a) Draw a reaction energy diagram for that mechanism, given that $\Delta H_{\text {overall }}^{\circ}=-226 \mathrm{~kJ} / \mathrm{mol}$.
(b) Consider the following alternative mechanism:
$\begin{array}{ll}\text { (1) } 2 \mathrm{NO}_{2}(g) \longrightarrow \mathrm{N}_{2}(g)+2 \mathrm{O}_{2}(g) & \text { [slow] } \\ \text { (2) } 2 \mathrm{CO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g) & \text { [fast] } \\ \text { (3) } \mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}(g) & \text { [fast] }\end{array}$ [for
Is the alternative mechanism consistent with the rate law? Is one mechanism more reasonable physically? Explain.
16.88 Consider the following general reaction and data:

$$
2 \mathrm{~A}+2 \mathrm{~B}+\mathrm{C} \longrightarrow \mathrm{D}+3 \mathrm{E}
$$

| Expt | Initial [A] <br> $(\mathrm{mol} / \mathrm{L})$ | Initial [B] <br> $(\mathrm{mol} / \mathrm{L})$ | Initial [C] <br> $(\mathrm{mol} / \mathrm{L})$ | Initial Rate <br> $(\mathrm{mol} / \mathrm{L} \cdot \mathrm{s})$ |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 0.024 | 0.085 | 0.032 | $6.0 \times 10^{-6}$ |
| 2 | 0.096 | 0.085 | 0.032 | $9.6 \times 10^{-5}$ |
| 3 | 0.024 | 0.034 | 0.080 | $1.5 \times 10^{-5}$ |
| 4 | 0.012 | 0.170 | 0.032 | $1.5 \times 10^{-6}$ |

(a) What is the reaction order with respect to each reactant?
(b) Calculate the rate constant.
(c) Write the rate law for this reaction.
(d) Express the rate in terms of changes in concentration with time for each of the components.
16.89 In acidic solution, the breakdown of sucrose into glucose and fructose has this rate law: rate $=k\left[\mathrm{H}^{+}\right][$sucrose $]$. The initial rate of sucrose breakdown is measured in a solution that is $0.01 \mathrm{M} \mathrm{H}^{+}, 1.0 \mathrm{M}$ sucrose, 0.1 M fructose, and 0.1 M glucose. How does the rate change if
(a) [Sucrose] is changed to 2.5 M ?
(b) [Sucrose], [fructose], and [glucose] are all changed to 0.5 M ?
(c) $\left[\mathrm{H}^{+}\right]$is changed to 0.0001 M ?
(d) $[$ Sucrose $]$ and $\left[\mathrm{H}^{+}\right]$are both changed to $0.1 M$ ?
16.90 Enzymes are remarkably efficient catalysts that can increase reaction rates by as many as 20 orders of magnitude.
(a) How does an enzyme affect the transition state of a reaction, and how does this effect increase the reaction rate?
(b) What characteristics of enzymes give them this tremendous effectiveness as catalysts?
16.91 The following molecular scenes represent starting mixtures I and II for the reaction of A (black) with B (orange):

Apago PDF

Each sphere counts as 0.010 mol , and the volume is 0.50 L . If the initial rate in I is $8.3 \times 10^{-4} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{min}$, what is the initial rate in II?
16.92 Biochemists consider the citric acid cycle to be the central reaction sequence in metabolism. One of the key steps is an oxidation catalyzed by the enzyme isocitrate dehydrogenase and the oxidizing agent $\mathrm{NAD}^{+}$. Under certain conditions, the reaction in yeast obeys 11th-order kinetics:

Rate $=k[$ enzyme $][\text { isocitrate }]^{4}[\text { AMP }]^{2}\left[\mathrm{NAD}^{+}\right]^{m}\left[\mathrm{Mg}^{2+}\right]^{2}$
What is the order with respect to $\mathrm{NAD}^{+}$?
16.93 At body temperature $\left(37^{\circ} \mathrm{C}\right), k$ of an enzyme-catalyzed reaction is $2.3 \times 10^{14}$ times greater than $k$ of the uncatalyzed reaction. Assuming that the frequency factor $A$ is the same for both reactions, by how much does the enzyme lower the $E_{\mathrm{a}}$ ?
16.94 Enzymes in the human liver catalyze a large number of reactions that degrade ingested toxic chemicals. By what factor is the rate of a detoxification reaction changed if a liver enzyme lowers the activation energy by $5 \mathrm{~kJ} / \mathrm{mol}$ at $37^{\circ} \mathrm{C}$ ?
16.95 Experiment shows that the rate of formation of carbon tetrachloride from chloroform,

$$
\mathrm{CHCl}_{3}(g)+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{CCl}_{4}(g)+\mathrm{HCl}(g)
$$

is first order in $\mathrm{CHCl}_{3}, \frac{1}{2}$ order in $\mathrm{Cl}_{2}$, and $\frac{3}{2}$ order overall. Show that the following mechanism is consistent with the rate law:
(1) $\mathrm{Cl}_{2}(g) \rightleftharpoons 2 \mathrm{Cl}(g)$
[fast]
(2) $\mathrm{Cl}(g)+\mathrm{CHCl}_{3}(g) \longrightarrow \mathrm{HCl}(g)+\mathrm{CCl}_{3}(g) \quad$ [slow]
(3) $\mathrm{CCl}_{3}(g)+\mathrm{Cl}(g) \longrightarrow \mathrm{CCl}_{4}(g) \quad$ [fast]
16.96 A biochemist studying breakdown of the insecticide DDT finds that it decomposes by a first-order reaction with a half-life of 12 yr . How long does it take DDT in a soil sample to decompose from 275 ppbm to 10 . ppbm (parts per billion by mass)?
16.97 Insulin is a polypeptide hormone released from the pancreas that stimulates fat and muscle to take up glucose. In a certain patient, it has a first-order half-life in the blood of 3.5 min . To maintain an adequate blood concentration of insulin, it must be replenished in a time interval equal to $1 / k$. How long is the time interval in this patient?
16.98 For the reaction $\mathrm{A}(g)+\mathrm{B}(g) \longrightarrow \mathrm{AB}(g)$, the rate is $0.20 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$, when $[\mathrm{A}]_{0}=[\mathrm{B}]_{0}=1.0 \mathrm{~mol} / \mathrm{L}$. If the reaction is first order in B and second order in A , what is the rate when $[\mathrm{A}]_{0}=2.0 \mathrm{~mol} / \mathrm{L}$ and $[\mathrm{B}]_{0}=3.0 \mathrm{~mol} / \mathrm{L}$ ?
16.99 The acid-catalyzed hydrolysis of sucrose occurs by the following overall reaction whose kinetic data are given below:

$$
\begin{gathered}
\underset{\text { sucrose }}{\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}(s)}+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(a q)+\mathrm{C}_{6} \mathrm{C}_{12} \mathrm{H}_{6}(a q) \\
\text { glucose } \\
\text { [Sucrose] (mol/L) }
\end{gathered} \text { Time (h) }
$$

(a) Determine the rate constant and the half-life of the reaction.
(b) How long does it take to hydrolyze $75 \%$ of the sucrose?
(c) Other studies have shown that this reaction is actually second order overall but appears to follow first-order kinetics. (Such a reaction is called a pseudo-first-order reaction.) Suggest a reason for this apparent first-order behavior.
16.100 Is each of these statements true? If not, explain why.
(a) At a given $T$, all molecules have the same kinetic energy.
(b) Halving the $P$ of a gaseous reaction doubles the rate.
(c) A higher activation energy gives a lower reaction rate.
(d) A temperature rise of $10^{\circ} \mathrm{C}$ doubles the rate of any reaction.
(e) If reactant molecules collide with greater energy than the activation energy, they change into product molecules.
(f) The activation energy of a reaction depends on temperature.
(g) The rate of a reaction increases as the reaction proceeds.
(h) Activation energy depends on collision frequency.
(i) A catalyst increases the rate by increasing collision frequency.
(j) Exothermic reactions are faster than endothermic reactions.
(k) Temperature has no effect on the frequency factor $(A)$.
(l) The activation energy of a reaction is lowered by a catalyst.
(m) For most reactions, $\Delta H_{\mathrm{rxn}}$ is lowered by a catalyst.
(n) The orientation probability factor $(p)$ is near 1 for reactions between single atoms.
(o) The initial rate of a reaction is its maximum rate.
(p) A bimolecular reaction is generally twice as fast as a unimolecular reaction.
(q) The molecularity of an elementary reaction is proportional to the molecular complexity of the reactant(s).
16.101 For the decomposition of gaseous dinitrogen pentaoxide, $2 \mathrm{~N}_{2} \mathrm{O}_{5}(g) \longrightarrow 4 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)$, the rate constant is $k=$ $2.8 \times 10^{-3} \mathrm{~s}^{-1}$ at $60^{\circ} \mathrm{C}$. The initial concentration of $\mathrm{N}_{2} \mathrm{O}_{5}$ is $1.58 \mathrm{~mol} / \mathrm{L}$. (a) What is $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ after 5.00 min ? (b) What fraction of the $\mathrm{N}_{2} \mathrm{O}_{5}$ has decomposed after 5.00 min ?
16.102 Even when a mechanism is consistent with the rate law, later work may show it to be incorrect. For example, the reaction between hydrogen and iodine has this rate law: rate $=k\left[\mathrm{H}_{2}\right]\left[\mathrm{I}_{2}\right]$. The long-accepted mechanism had a single bimolecular step; that is, the overall reaction was thought to be elementary:

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \longrightarrow 2 \mathrm{HI}(g)
$$

In the 1960s, however, spectroscopic evidence showed the presence of free I atoms during the reaction. Kineticists have since proposed a three-step mechanism:
(1) $\mathrm{I}_{2}(g) \rightleftharpoons 2 \mathrm{I}(g)$
[fast]
(2) $\mathrm{H}_{2}(g)+\mathrm{I}(g) \rightleftharpoons \mathrm{H}_{2} \mathrm{I}(g) \quad$ [fast]
(3) $\mathrm{H}_{2} \mathrm{I}(g)+\mathrm{I}(g) \longrightarrow 2 \mathrm{HI}(g) \quad$ [slow]

Show that this mechanism is consistent with the rate law.
16.103 Suggest an experimental method for measuring the change in concentration with time for each of the following reactions:
(a) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{Br}(l)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}(l)+\mathrm{HBr}(a q)$
(b) $2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{NOCl}(g)$
16.104 An atmospheric chemist fills a container with gaseous $\mathrm{N}_{2} \mathrm{O}_{5}$ to a pressure of 125 kPa , and the gas decomposes to $\mathrm{NO}_{2}$ and $\mathrm{O}_{2}$. What is the partial pressure of $\mathrm{NO}_{2}, P_{\mathrm{NO}_{2}}$ (in kPa ), when the total pressure is 178 kPa ?
16.105 Many drugs decompose in blood by a first-order process. (a) Two tablets of aspirin supply 0.60 g of the active compound. After 30 min , this compound reaches a maximum concentration of $2 \mathrm{mg} / 100 \mathrm{~mL}$ of blood. If the half-tite forgts break-D down is 90 min , what is its concentration (in $\mathrm{mg} / 100 \mathrm{~mL}$ ) 2.5 h after it reaches its maximum concentration?
(b) For the decomposition of an antibiotic in a person with a normal temperature $\left(98.6^{\circ} \mathrm{F}\right), k=3.1 \times 10^{-5} \mathrm{~s}^{-1}$; for a person with a fever at $101.9^{\circ} \mathrm{F}, k=3.9 \times 10^{-5} \mathrm{~s}^{-1}$. If the person with the fever must take another pill when $\frac{2}{3}$ of the first pill has decomposed, how many hours should she wait to take a second pill? A third pill? (Assume the pill is effective immediately.)
(c) Calculate $E_{\mathrm{a}}$ for decomposition of the antibiotic in part (b).
16.106 While developing a catalytic process to make ethylene glycol from synthesis gas $\left(\mathrm{CO}+\mathrm{H}_{2}\right)$, a chemical engineer finds the rate is fourth order in gas pressure. The uncertainty in the pressure reading is $5 \%$. When the catalyst is modified, the rate increases by $10 \%$. If you were the company patent attorney, would you file for a patent on this catalyst modification? Explain.
16.107 Iodide ion reacts with chloromethane to displace chloride ion in a common organic substitution reaction:

$$
\mathrm{I}^{-}+\mathrm{CH}_{3} \mathrm{Cl} \longrightarrow \mathrm{CH}_{3} \mathrm{I}+\mathrm{Cl}^{-}
$$

(a) Draw a wedge-bond structure of chloroform and indicate the most effective direction of $\mathrm{I}^{-}$attack.
(b) The analogous reaction with 2-chlorobutane [Figure P16.107(b)] results in a major change in specific rotation as measured by polarimetry. Explain, showing a wedge-bond structure of the product.
(c) Under different conditions, 2-chlorobutane loses $\mathrm{Cl}^{-}$in a rate-determining step to form a planar intermediate [Figure P16.107(c)]. This cationic species reacts with HI and then loses $\mathrm{H}^{+}$to form a product that exhibits no optical activity. Explain, showing a wedge-bond structure.

Figure P16.107(b)

Figure P16.107(c)
16.108 Assume water boils at $100.0^{\circ} \mathrm{C}$ in Houston (near sea level), and at $90.0^{\circ} \mathrm{C}$ in Cripple Creek, Colorado (near 9500 ft ). If it takes 4.8 min to cook an egg in Cripple Creek and 4.5 min in Houston, what is $E_{\mathrm{a}}$ for this process?
16.109 Sulfonation of benzene has the following mechanism:
(1) $2 \mathrm{H}_{2} \mathrm{SO}_{4} \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{HSO}_{4}^{-}+\mathrm{SO}_{3}$ [fast]
(2) $\mathrm{SO}_{3}+\mathrm{C}_{6} \mathrm{H}_{6} \longrightarrow \mathrm{H}\left(\mathrm{C}_{6} \mathrm{H}_{5}{ }^{+}\right) \mathrm{SO}_{3}{ }^{-} \quad$ [slow]
(3) $\mathrm{H}\left(\mathrm{C}_{6} \mathrm{H}_{5}{ }^{+}\right) \mathrm{SO}_{3}{ }^{-}+\mathrm{HSO}_{4}^{-} \longrightarrow \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{SO}_{3}{ }^{-}+\mathrm{H}_{2} \mathrm{SO}_{4}$ [fast]
(4) $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{SO}_{3}^{-}+\mathrm{H}_{3} \mathrm{O}^{+} \longrightarrow \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{SO}_{3} \mathrm{H}+\mathrm{H}_{2} \mathrm{O} \quad$ [fast]
(a) Write an overall equation for the reaction.
(b) Write the overall rate law for the initial rate of the reaction. 16.110 In the lower troposphere, ozone is one of the components of photochemical smog. It is generated in air when nitrogen dioxide, formed by the oxidation of nitrogen monoxide from car exhaust, reacts by the following mechanism:
(1) $\mathrm{NO}_{2}(g) \xrightarrow[h v]{k_{1}} \mathrm{NO}(g)+\mathrm{O}(g)$
(2) $\mathrm{O}(g)+\mathrm{O}_{2}(g) \xrightarrow{k_{2}} \mathrm{O}_{3}(g)$

Assuming the rate of formation of atomic oxygen in step 1 equals the rate of its consumption in step 2 , use the data below to cafcuate (a) the confentration of atomic oxygen [O]; (b) the rate of ozone formation.

$$
\begin{array}{lr}
k_{1}=6.0 \times 10^{-3} \mathrm{~s}^{-1} & {\left[\mathrm{NO}_{2}\right]=4.0 \times 10^{-9} \mathrm{M}} \\
k_{2}=1.0 \times 10^{6} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{~s} & {\left[\mathrm{O}_{2}\right]=1.0 \times 10^{-2} \mathrm{M}}
\end{array}
$$

16.111 Chlorine is commonly used to disinfect drinking water, and inactivation of pathogens by chlorine follows first-order kinetics. The following data show $E$. coli inactivation:

| Contact time (min) | Percent (\%) inactivation |
| :---: | :---: |
| 0.00 | 0.0 |
| 0.50 | 68.3 |
| 1.00 | 90.0 |
| 1.50 | 96.8 |
| 2.00 | 99.0 |
| 2.50 | 99.7 |
| 3.00 | 99.9 |

(a) Determine the first-order inactivation constant, k. [Hint: $\%$ inactivation $=100 \times\left(1-[\mathrm{A}]_{t} /[\mathrm{A}]_{0}\right)$.]
(b) How much contact time is required for $95 \%$ inactivation?
16.112 The reaction and rate law for the gas-phase decomposition of dinitrogen pentaoxide are

$$
2 \mathrm{~N}_{2} \mathrm{O}_{5}(g) \longrightarrow 4 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g) \quad \text { rate }=k\left[\mathrm{~N}_{2} \mathrm{O}_{5}\right]
$$

Which of the following can be considered valid mechanisms for the reaction?
I One-step collision
II $2 \mathrm{~N}_{2} \mathrm{O}_{5}(g) \longrightarrow 2 \mathrm{NO}_{3}(g)+2 \mathrm{NO}_{2}(g) \quad$ [slow] $2 \mathrm{NO}_{3}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)+2 \mathrm{O}(g) \quad$ [fast]
$2 \mathrm{O}(\mathrm{g}) \longrightarrow \mathrm{O}_{2}(\mathrm{~g}) \quad$ [fast]

| III $\mathrm{N}_{2} \mathrm{O}_{5}(g) \rightleftharpoons \mathrm{NO}_{3}(g)+\mathrm{NO}_{2}(g)$ | [fast] |
| :---: | :--- |
| $\mathrm{NO}_{2}(g)+\mathrm{N}_{2} \mathrm{O}_{5}(g) \longrightarrow 3 \mathrm{NO}_{2}(g)+\mathrm{O}(g)$ | [slow] |
| $\mathrm{NO}_{3}(g)+\mathrm{O}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)$ | [fast] |
| IV $2 \mathrm{~N}_{2} \mathrm{O}_{5}(g) \rightleftharpoons$ | $2 \mathrm{NO}_{2}(g)+\mathrm{N}_{2} \mathrm{O}_{3}(g)+3 \mathrm{O}(g)$ |
| $\left.\mathrm{N}_{2} \mathrm{O}_{3}(g)+\mathrm{O}(g) \longrightarrow 2 \mathrm{Nast}^{2}\right]$ |  |
| $2 \mathrm{O}(g) \longrightarrow \mathrm{O}_{2}(g)$ | [slow] |
| V $2 \mathrm{~N}_{2} \mathrm{O}_{5}(g) \longrightarrow \mathrm{N}_{4} \mathrm{O}_{10}(g)$ | [fast] |
| $\mathrm{N}_{4} \mathrm{O}_{10}(g) \longrightarrow 4 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)$ | [slow] |
|  | [fast] |

16.113 Nitrification is a biological process for removing $\mathrm{NH}_{3}$ from wastewater as $\mathrm{NH}_{4}{ }^{+}$:

$$
\mathrm{NH}_{4}^{+}+2 \mathrm{O}_{2} \longrightarrow \mathrm{NO}_{3}^{-}+2 \mathrm{H}^{+}+\mathrm{H}_{2} \mathrm{O}
$$

The first-order rate constant is given as

$$
k_{1}=0.47 e^{0.095\left(T-15^{\circ} \mathrm{C}\right)}
$$

where $k_{1}$ is in day ${ }^{-1}$ and $T$ is in ${ }^{\circ} \mathrm{C}$.
(a) If the initial concentration of $\mathrm{NH}_{3}$ is $3.0 \mathrm{~mol} / \mathrm{m}^{3}$, how long will it take to reduce the concentration to $0.35 \mathrm{~mol} / \mathrm{m}^{3}$ in the spring $\left(T=20^{\circ} \mathrm{C}\right)$ ? (b) In the winter $\left(T=10^{\circ} \mathrm{C}\right)$ ? (c) Using your answer to part (a), what is the rate of $\mathrm{O}_{2}$ consumption?
16.114 Carbon disulfide, a poisonous, flammable liquid, is an excellent solvent for phosphorus, sulfur, and some other nonmetals. A kinetic study of its gaseous decomposition reveals these data:

| Experiment | $\begin{aligned} & \text { Initial }\left[\mathrm{CS}_{2}\right] \\ & (\mathrm{mol} / \mathrm{L}) \end{aligned}$ | Initial Rate ( $\mathrm{mol} / \mathrm{L} \cdot \mathrm{s}$ ) |
| :---: | :---: | :---: |
| 1 | 0.100 | $2.7 \times 10^{-7}$ |
| 2 | 0.080 | $2.2 \times 10^{-7}$ |
| 3 | 0.055 | $1.5 \times 10^{-7}$ |
| 4 | 0.044 | APagao-PDE |

(a) Write the rate law for the decomposition of $\mathrm{CS}_{2}$.
(b) Calculate the average value of the rate constant.
16.115 Like any catalyst, palladium, platinum, and nickel catalyze both directions of a reaction: addition of hydrogen to (hydrogenation) and its elimination from (dehydrogenation) carbon double bonds.
(a) Which variable determines whether an alkene will be hydrogenated or dehydrogenated?
(b) Which reaction requires a higher temperature?
(c) How can all-trans fats arise during hydrogenation of fats that contain some cis- double bonds?
16.116 In a clock reaction, a dramatic color change occurs at a time determined by concentration and temperature. Consider the iodine clock reaction, whose overall equation is

$$
2 \mathrm{I}^{-}(a q)+\mathrm{S}_{2} \mathrm{O}_{8}{ }^{2-}(a q) \longrightarrow \mathrm{I}_{2}(a q)+2 \mathrm{SO}_{4}{ }^{2-}(a q)
$$

As $\mathrm{I}_{2}$ forms, it is immediately consumed by its reaction with a fixed amount of added $\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}$ :

$$
\mathrm{I}_{2}(a q)+2 \mathrm{~S}_{2} \mathrm{O}_{3}{ }^{2-}(a q) \longrightarrow 2 \mathrm{I}^{-}(a q)+\mathrm{S}_{4} \mathrm{O}_{6}{ }^{2-}(a q)
$$

Once the $\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}$ is consumed, the excess $\mathrm{I}_{2}$ forms a blue-black product with starch present in solution:

$$
\mathrm{I}_{2}+\text { starch } \longrightarrow \text { starch } \cdot \mathrm{I}_{2} \text { (blue-black) }
$$

The rate of the reaction is also influenced by the total concentration of ions, so KCl and $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}$ are added to maintain a constant value. Use the data below, obtained at $23^{\circ} \mathrm{C}$, to determine
(a) The average rate for each trial
(b) The order with respect to each reactant
(c) The rate constant
(d) The rate law for the overall reaction

| Expt 1 | Expt 2 | Expt 3 |
| :---: | ---: | :---: |
| 10.0 | 20.0 | 20.0 |
| 20.0 | 20.0 | 10.0 |
| 10.0 | 10.0 | 10.0 |
| 10.0 | 0.0 | 0.0 |
| 0.0 | 0.0 | 10.0 |
| 29.0 | 14.5 | 14.5 |

16.117 Heat transfer to and from a reaction flask is often a critical factor in controlling reaction rate. The heat transferred $(q)$ depends on a heat transfer coefficient $(h)$ for the flask material, the temperature difference $(\Delta T)$ across the flask wall, and the commonly "wetted" area $(A)$ of the flask and bath, $q=h \cdot A \cdot \Delta T$. When an exothermic reaction is run at a given $T$, there is a bath temperature at which the reaction can no longer be controlled, and the reaction "runs away" suddenly. A similar problem is often seen when a reaction is "scaled up" from, say, a half-filled small flask to a half-filled large flask. Explain these behaviors. 16.118 The molecular scenes below represent the first-order reaction as cyclopropane (red) is converted to propene (green):

Fibleanfeque half-life and (b) the first-order rate constant. 16.119 The growth of Pseudomonas bacteria is modeled as a firstorder process with $k=0.035 \mathrm{~min}^{-1}$ at $37^{\circ} \mathrm{C}$. The initial Pseudomonas population density is $1.0 \times 10^{3}$ cells/L. (a) What is the population density after 2 h ? (b) What is the time required for the population to go from $1.0 \times 10^{3}$ to $2.0 \times 10^{3}$ cells/ L?
16.120 Consider the following organic reaction, in which one halogen replaces another in an alkyl halide:

$$
\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{Br}+\mathrm{KI} \longrightarrow \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{I}+\mathrm{KBr}
$$

In acetone, this particular reaction goes to completion because KI is soluble in acetone but KBr is not. In the mechanism, $\mathrm{I}^{-}$ approaches the carbon opposite to the Br (see Figure 16.19, with $\mathrm{I}^{-}$instead of $\mathrm{OH}^{-}$). After $\mathrm{Br}^{-}$has been replaced by $\mathrm{I}^{-}$ and precipitates as KBr , other $\mathrm{I}^{-}$ions react with the ethyl iodide by the same mechanism.
(a) If we designate the carbon bonded to the halogen as $\mathrm{C}-1$, what is the shape around $\mathrm{C}-1$ and the hybridization of $\mathrm{C}-1$ in ethyl iodide?
(b) In the transition state, one of the two lobes of the unhybridized $2 p$ orbital of $\mathrm{C}-1$ overlaps a $p$ orbital of I , while the other lobe overlaps a $p$ orbital of Br . What is the shape around $\mathrm{C}-1$ and the hybridization of $\mathrm{C}-1$ in the transition state?
(c) The deuterated reactant, $\mathrm{CH}_{3} \mathrm{CHDBr}$ (where D is deuterium, ${ }^{2} \mathrm{H}$ ), has two optical isomers because $\mathrm{C}-1$ is chiral. If the reaction is run with one of the isomers, the ethyl iodide is not optically active. Explain.
16.121 Another radioisotope of iodine, ${ }^{131} \mathrm{I}$, is also used to study thyroid function (see Follow-up Problem 16.7). A patient is given a sample that is $1.7 \times 10^{-4} M^{131} \mathrm{I}$. If the half-life is 8.04 days, what fraction of the radioactivity remains after 30 . days?
16.122 The effect of substrate concentration on the first-order microbial growth rate follows the Monod equation:

$$
\mu=\frac{\mu_{\max } S}{K_{\mathrm{s}}+S}
$$

where $\mu$ is the first-order growth rate $\left(s^{-1}\right), \mu_{\max }$ is the maximum growth rate $\left(\mathrm{s}^{-1}\right), S$ is the substrate concentration $\left(\mathrm{kg} / \mathrm{m}^{3}\right)$, and $K_{\mathrm{s}}$ is the half-saturation coefficient $\left(\mathrm{kg} / \mathrm{m}^{3}\right)$. For $\mu_{\text {max }}=1.5 \times 10^{-4} \mathrm{~s}^{-1}$ and $K_{\mathrm{s}}=0.03 \mathrm{~kg} / \mathrm{m}^{3}$ :
(a) Prepare a plot of $\mu$ vs. $S$ for $S$ between 0.0 and $1.0 \mathrm{~kg} / \mathrm{m}^{3}$.
(b) The initial population density is $5.0 \times 10^{3}$ cells $/ \mathrm{m}^{3}$. What is the density after 1.0 h , if the initial $S$ is $0.30 \mathrm{~kg} / \mathrm{m}^{3}$ ?
(c) What is it if the initial $S$ is $0.70 \mathrm{~kg} / \mathrm{m}^{3}$ ?
16.123 The scenes depict four initial reaction mixtures for the reaction of A (blue) and B (yellow), with and without a solid present (gray cubes). The initial rate, $-\Delta[\mathrm{A}] / \Delta t$ (in mol/L•s), is shown for each sphere representing 0.010 mol and the container volume at 0.50 L .

III $5.6 \times 10^{-4}$

IV $4.9 \times 10^{-4}$
(a) What is the rate law in the absence of a catalyst?
(b) What is the overall reaction order?
(c) Find the rate constant.
(d) Do the gray cubes have a catalytic effect? Explain.
16.124 The mathematics of the first-order rate law can be applied to any situation in which a quantity decreases by a constant fraction per unit of time (or any other variable).
(a) As light moves through a solution, its intensity decreases per unit distance traveled in the solution. Show that $\ln \left(\frac{\text { intensity of light leaving the solution }}{\text { intensity of light entering the solution }}\right)$
$=-$ fraction of light removed per unit of length $\times$ distance traveled in solution
(b) The value of your savings declines under conditions of constant inflation. Show that
$\ln \left(\frac{\text { value remaining }}{\text { initial value }}\right)$
$=-$ fraction lost per unit of time $\times$ savings time interval
16.125 Figure 16.24 (p. 722) shows key steps in the metalcatalyzed (M) hydrogenation of ethylene:

$$
\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})+\mathrm{H}_{2}(\mathrm{~g}) \xrightarrow{\mathrm{M}} \mathrm{C}_{2} \mathrm{H}_{6}(\mathrm{~g})
$$

Use the following symbols to write a mechanism that gives the overall equation:
$\mathrm{H}_{2}$ (ads) adsorbed hydrogen molecules
M-H hydrogen atoms bonded to metal atoms
$\mathrm{C}_{2} \mathrm{H}_{4}$ (ads) adsorbed ethylene molecules
$\mathrm{C}_{2} \mathrm{H}_{5}$ (ads) adsorbed ethyl radicals
16.126 Acetone is one of the most important solvents in organic chemistry, used to dissolve everything from fats and waxes to airplane glue and nail polish. At high temperatures, it decomposes in a first-order process to methane and ketene $\left(\mathrm{CH}_{2}=\mathrm{C}=\mathrm{O}\right)$. At $600^{\circ} \mathrm{C}$, the rate constant is $8.7 \times 10^{-3} \mathrm{~s}^{-1}$.
(a) What is the half-life of the reaction?
(b) How long does it take for $40 . \%$ of a sample of acetone to

PDE decrpposed
(c) How Tong does it take for $90 . \%$ of a sample of acetone to decompose?
16.127 A (green), B (blue), and C (red) are structural isomers. The molecular filmstrip depicts them undergoing a chemical change as time proceeds.

(a) Write a mechanism for the reaction.
(b) What role does C play?

Juggling Equilibrium Like the opposing steps of a reversible reaction, balls passing back and forth between the hands of a juggler move at equal rates in both directions. This chapter-the first of three to examine dynamic equilibrium, which is the universal condition of chemical change-focuses primarily on equilibrium in gaseous systems.

## Equilibrium: The Extent of Chemical Reactions

### 17.1 The Equilibrium State and the Equilibrium Constant

17.2 The Reaction Quotient and the Equilibrium Constant Writing the Reaction Quotient Variations in the Form of $Q$

17.5 How to Solve Equilibrium Problems Using Quantities to Determine K Using $K$ to Determine Quantities Determining Reaction Direction
17.6 Reaction Conditions and the Equilibrium State: Le Châtelier's Principle Change in Concentration Change in Pressure (Volume) Change in Temperature Lack of Effect of a Catalyst

## Concepts \& Skills to Review before you study this chapter

- reversibility of reactions (Section 4.7)
- equilibrium vapor pressure (Section 12.2)
- equilibrium nature of a saturated solution (Section 13.4)
- dependence of rate on concentration (Sections 16.2 and 16.6)
- rate laws for elementary reactions (Section 16.7)
- function of a catalyst (Section 16.8)

0ur study of kinetics in Chapter 16 addressed one of three central questions in reaction chemistry, that of reaction rate, which also concerns mechanism. Now we turn to the second question, which we previewed in Chapter 4: how much product forms under a given set of starting concentrations and conditions? The principles of kinetics and equilibrium apply to different aspects of a reaction:

- Kinetics applies to the speed (or rate) of a reaction, the concentration of reactant that disappears (or of product that appears) per unit time.
- Equilibrium applies to the extent of a reaction, the concentrations of reactant and product present after an unlimited time, or once no further change occurs.

Just as reactions vary greatly in their speed, they also vary in their extent. A fast reaction may go almost completely or barely at all toward products. Consider the dissociation of an acid in water. In 1 M HCl , virtually all the hydrogen chloride molecules are dissociated into ions. In contrast, in $1 M \mathrm{CH}_{3} \mathrm{COOH}$, fewer than $1 \%$ of the acetic acid molecules are dissociated at any given time. Yet both reactions take less than a second to reach completion. Similarly, some slow reactions eventually yield a large amount of product, whereas others yield very little. After a few years at ordinary temperatures, a steel water-storage tank will rust, and it will do so completely given enough time; but no matter how long you wait, the water inside will not decompose to hydrogen and oxygen.

Knowing the extent of a given reaction is crucial. How much productmedicine, polymer, or fuel-can you obtain from a particular reaction mixture? How can you adjust conditions to obtain more? If a reaction is slow but has a good yield, will a catalyst speed it up enough to make it useful?

IN THIS CHAPTER . . . We consider equilibrium principles in systems of gases and pure liquids and solids; we'll discuss various solution equilibria in Chapters 18 and
19. Throughout these chapters, you'll learn how to solve the major kinds of equilibrium problems. We first examine the equilibrium state at the macroscopic and molecular levels. Then we focus on the relation between the reaction quotient, which changes as the reaction proceeds, and the equilibrium constant, which applies to the system at equilibrium. We express the equilibrium condition in terms of concentrations or pressures. Then we see how to determine whether a system is proceeding toward products or reactants as it approaches equilibrium. We examine how reaction conditions affect the equilibrium state and end with applications of equilibrium in metabolism and in industrial production.

### 17.1 THE EQUILIBRIUM STATE AND THE EQUILIBRIUM CONSTANT

Countless experiments with chemical systems have shown that, given sufficient time, the concentrations of reactants and products no longer change. This apparent cessation of chemical activity occurs because all reactions are reversible and reach a state of equilibrium. Let's examine a chemical system at the macroscopic and molecular levels to see how the equilibrium state arises. The system consists of two gases, colorless dinitrogen tetraoxide and brown nitrogen dioxide:

$$
\mathrm{N}_{2} \mathrm{O}_{4}(g ; \text { colorless }) \rightleftharpoons 2 \mathrm{NO}_{2}(g ; \text { brown })
$$

When we introduce some $\mathrm{N}_{2} \mathrm{O}_{4}(l)$ into a sealed flask kept at $200^{\circ} \mathrm{C}$, a change occurs immediately. The liquid vaporizes $\left(\mathrm{bp}=21^{\circ} \mathrm{C}\right)$ and the gas begins to turn pale brown. The color darkens, and after a few moments, the color stops changing, as shown in Figure 17.1.

Figure 17.1 Reaching the equilibrium state for the reaction $\mathrm{N}_{2} \mathrm{O}_{4} \rightleftharpoons 2 \mathrm{NO}_{2}$ on the macroscopic and molecular levels. A, When the experiment begins, the reaction mixture consists mostly of colorless $\mathrm{N}_{2} \mathrm{O}_{4}$. B, As $\mathrm{N}_{2} \mathrm{O}_{4}$ decomposes to reddish brown $\mathrm{NO}_{2}$, the color of the mixture becomes pale brown. $\mathbf{C}$, When equilibrium is

reached, the concentrations of $\mathrm{NO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}_{4}$ are constant, and the color reaches its final intensity. $\mathbf{D}$, Because the reaction continues in the forward and reverse directions at equal rates, the concentrations (and color) remain constant.

On the molecular level, a much more dynamic scene unfolds. The $\mathrm{N}_{2} \mathrm{O}_{4}$ molecules fly wildly throughout the flask, a few splitting into two $\mathrm{NO}_{2}$ molecules. As time passes, more $\mathrm{N}_{2} \mathrm{O}_{4}$ molecules decompose and the concentration of $\mathrm{NO}_{2}$ rises.
 $\mathrm{NO}_{2}$ is reddish brown. As the number of $\mathrm{N}_{2} \mathrm{O}_{4}$ molecules decreases, $\mathrm{N}_{2} \mathrm{O}_{4}$ decomposition slows. At the same time, increasing numbers of $\mathrm{NO}_{2}$ molecules collide and combine, so re-formation of $\mathrm{N}_{2} \mathrm{O}_{4}$ speeds up. Eventually, $\mathrm{N}_{2} \mathrm{O}_{4}$ molecules decompose into $\mathrm{NO}_{2}$ molecules as fast as the $\mathrm{NO}_{2}$ molecules combine into $\mathrm{N}_{2} \mathrm{O}_{4}$. The system has reached equilibrium: reactant and product concentrations stop changing because the forward and reverse rates have become equal:

$$
\begin{equation*}
\text { At equilibrium: } \text { rate }_{\mathrm{fwd}}=\text { rate }_{\mathrm{rev}} \tag{17.1}
\end{equation*}
$$

Thus, a system at equilibrium continues to be dynamic at the molecular level, but we observe no further net change because changes in one direction are balanced by changes in the other.

At a particular temperature, when the system reaches equilibrium, product and reactant concentrations are constant. Therefore, their ratio must be a constant. We'll use the $\mathrm{N}_{2} \mathrm{O}_{4}-\mathrm{NO}_{2}$ system to derive this constant. At equilibrium, we have

$$
\text { rate }_{\text {fwd }}=\text { rate }_{\mathrm{rev}}
$$

In this case, both forward and reverse reactions are elementary steps (Section 16.7), so we can write their rate laws directly from the balanced equation:

$$
k_{\mathrm{fwd}}\left[\mathrm{~N}_{2} \mathrm{O}_{4}\right]_{\mathrm{eq}}=k_{\mathrm{rev}}\left[\mathrm{NO}_{2}\right]_{\mathrm{eq}}^{2}
$$

where $k_{\text {fwd }}$ and $k_{\text {rev }}$ are the forward and reverse rate constants, respectively, and the subscript "eq" refers to concentrations at equilibrium. By rearranging, we set the ratio of the rate constants equal to the ratio of the concentration terms:

$$
\frac{k_{\mathrm{fwd}}}{k_{\mathrm{rev}}}=\frac{\left[\mathrm{NO}_{2}\right]_{\mathrm{eq}}^{2}}{\left[\mathrm{~N}_{2} \mathrm{O}_{4}\right]_{\mathrm{eq}}}
$$

The ratio of constants gives rise to a new overall constant called the equilibrium constant (K):

$$
\begin{equation*}
K=\frac{k_{\mathrm{fwd}}}{k_{\mathrm{rev}}}=\frac{\left[\mathrm{NO}_{2}\right]_{\mathrm{eq}}^{2}}{\left[\mathrm{~N}_{2} \mathrm{O}_{4}\right]_{\mathrm{eq}}} \tag{17.2}
\end{equation*}
$$

The equilibrium constant $K$ is a number equal to a particular ratio of equilibrium concentrations of product and reactant at a particular temperature. We examine this idea closely in the next section and show that it holds as well for overall reactions made up of several elementary steps.

The magnitude of $K$ is an indication of how far a reaction proceeds toward product at a given temperature. Remember, it is the opposing rates that are equal at equilibrium, not necessarily the concentrations. Indeed, different reactions, even at the same temperature, have a wide range of concentrations at equilibriumfrom almost all reactant to almost all product-and, therefore, they have a wide range of equilibrium constants (Figure 17.2). Here are three examples of different magnitudes of $K$ :

1. Small $K$. If a reaction yields very little product before reaching equilibrium, it has a small $K$, and we may even say it looks like there is "no reaction." For example, the oxidation of nitrogen barely proceeds at 1000 K :*

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}(g) \quad K=1 \times 10^{-30}
$$

2. Large $K$. Conversely, if a reaction reaches equilibrium with very little reactant remaining, it has a large $K$, and we say it "goes to completion." The oxidation of carbon monoxide goes to completion at 1000 K :

$$
2 \mathrm{CO}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{CO}_{2}(g) \quad K=2.2 \times 10^{22}
$$

3. Intermediate $K$. When significant amounts of both reactant and product are Apesentyanequibritm, Khabaninternediate value, as when bromine monochloride breaks down to its elements at 1000 K :

$$
2 \mathrm{BrCl}(g) \rightleftharpoons \mathrm{Br}_{2}(g)+\mathrm{Cl}_{2}(g) \quad K=5
$$

*To distinguish the equilibrium constant from the Kelvin temperature unit, the equilibrium constant is written with an uppercase italic $K$, whereas the kelvin is an uppercase roman K. Also, since the kelvin is a unit, it always follows a number.

Figure 17.2 The range of equilibrium constants. A, A system that reaches equilibrium with very little product has a small $K$. For this reaction, $K=1 / 49=0.020$. B, A system that reaches equilibrium with nearly all product has a large $K$. For this reaction, $K=49 / 1=49$.

C, A system that reaches equilibrium with significant concentrations of reactant and product has an intermediate $K$. For this reaction, $K=25 / 25=1.0$.

## Section Summary

Kinetics and equilibrium are distinct aspects of a reaction system, and the rate and extent of a reaction are not necessarily related. - When the forward and reverse reactions occur at the same rate, the system has reached dynamic equilibrium and concentrations no longer change. - The equilibrium constant $(K)$ is a number based on a particular ratio of product and reactant concentrations: $K$ is small for reactions that reach equilibrium with a high concentration of reactant(s) and large for reactions that reach equilibrium with a low concentration of reactant(s).

### 17.2 THE REACTION QUOTIENT AND THE EQUILIBRIUM CONSTANT

Our derivation of the equilibrium constant in Section 17.1 was based on kinetics. But the fundamental observation of equilibrium studies was stated many years before the principles of kinetics were developed. In 1864, two Norwegian chemists, Cato Guldberg and Peter Waage, observed that at a given temperature, a chemical system reaches a state in which a particular ratio of reactant and product concentrations has a constant value. This is one way of stating the law of chemical equilibrium, or the law of mass action. Note that there is no mention of rates.

In their formulating of the law of mass action, Guldberg and Waage found that, for a particular system and temperature, the same equilibrium state is attained regardless of how the reaction is run. For example, in the $\mathrm{N}_{2} \mathrm{O}_{4}-\mathrm{NO}_{2}$ system at $200^{\circ} \mathrm{C}$, we can start with pure reactant $\left(\mathrm{N}_{2} \mathrm{O}_{4}\right)$, pure product $\left(\mathrm{NO}_{2}\right)$, or any mixture of $\mathrm{NO}_{2}$ and $\mathrm{N}_{2} \mathrm{O}_{4}$, and the ratio of concentrations will attain the same equilibrium value (within experimenta euro PDF Fnhanceェ

The particular ratio of concentration terms that we write for a given reaction is called the reaction quotient ( $Q$, also known as the mass-action expression). For the breakdown of $\mathrm{N}_{2} \mathrm{O}_{4}$ to form $\mathrm{NO}_{2}$, the reaction quotient, which is based directly on the balanced equation, is

$$
\begin{gathered}
\mathrm{N}_{2} \mathrm{O}_{4}(g) \longrightarrow 2 \mathrm{NO}_{2}(g) \\
Q=\frac{\left[\mathrm{NO}_{2}\right]^{2}}{\left[\mathrm{~N}_{2} \mathrm{O}_{4}\right]}
\end{gathered}
$$

As the reaction proceeds toward the equilibrium state, there is a continual, smooth change in the concentrations of reactants and products. Thus, the ratio of concentrations also changes: at the beginning of the reaction, the concentrations have initial values, and $Q$ has an initial value; a moment later, after the reaction has proceeded a bit, the concentrations have slightly different values, and so does $Q$; another moment into the reaction, and there is more change in the concentrations and more change in $Q$; and on and on, until the reacting system reaches equilibrium. At that point, at a given temperature, the reactant and product concentrations have reached their equilibrium levels and no longer change. And the value of $Q$ has reached its equilibrium value and no longer changes. It equals $K$ at that temperature:

$$
\begin{equation*}
\text { At equilibrium: } Q=K \tag{17.3}
\end{equation*}
$$

Therefore, monitoring $Q$ tells whether the system has reached equilibrium, how far away it is if it has not, and, as we discuss later, in which direction it is changing to reach equilibrium. The data from four experiments are presented in

| Expt | Initial |  | $\frac{\text { Ratio (Q) }}{\left[\mathrm{NO}_{2}\right]^{2} /\left[\mathrm{N}_{2} \mathrm{O}_{4}\right]}$ | Equilibrium |  | Ratio (K) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | [ $\mathrm{N}_{2} \mathrm{O}_{4}$ ] | [ $\mathrm{NO}_{2}$ ] |  | $\left[\mathrm{N}_{2} \mathrm{O}_{4}\right]_{\mathrm{eq}}$ | $\left[\mathrm{NO}_{2}\right]_{\text {eq }}$ | $\left[\mathrm{NO}_{2}\right]_{\mathrm{eq}}^{2} /\left[\mathrm{N}_{2} \mathrm{O}_{4}\right]_{\text {eq }}$ |
| 1 | 0.1000 | 0.0000 | 0.0000 | 0.00357 | 0.193 | 10.4 |
| 2 | 0.0000 | 0.1000 | $\infty$ | $9.24 \times 10^{-4}$ | $9.82 \times 10^{-2}$ | 10.4 |
| 3 | 0.0500 | 0.0500 | 0.0500 | 0.00204 | 0.146 | 10.4 |
| 4 | 0.0750 | 0.0250 | 0.00833 | 0.00275 | 0.170 | 10.5 |

Figure 17.3 The change in $Q$ during the $\mathrm{N}_{2} \mathrm{O}_{4}-\mathrm{NO}_{2}$ reaction. The curved plots and the darkening brown screen above them show that $\left[\mathrm{N}_{2} \mathrm{O}_{4}\right]$ and $\left[\mathrm{NO}_{2}\right]$, and therefore the value of $Q$, change with time. Before equilibrium is reached, the concentrations are changing continuously, so $Q \neq K$. Once equilibrium is reached (vertical line) and at any time thereafter, $Q=K$.

Table 17.1. Each is a different run of the $\mathrm{N}_{2} \mathrm{O}_{4}-\mathrm{NO}_{2}$ reaction at $200^{\circ} \mathrm{C}$. There are two essential points to note:

- The ratio of initial concentrations varies widely but always gives the same ratio of equilibrium concentrations.
- The individual equilibrium concentrations are different in each case, but the ratio of these equilibrium concentrations is constant.
The curves in Figure 17.3 show experiment 1 in Table 17.1. Note that $\left[\mathrm{N}_{2} \mathrm{O}_{4}\right]$ and $\left[\mathrm{NO}_{2}\right]$ change smoothly during the course of the reaction and, thus, so does the value of $Q$. Once the system reaches equilibrium, as indicated by the constant brown color at the top, the concentrations no longer change and $Q$ equals $K$. In other words, for any given chemical system, $K$ is a special value of $Q$ that occurs when the reactant and product terms have their equilibrium values.

## Writing the Reaction Quotient

In Chapter 16, you saw that the rate law for an overall reaction cannot be written from the balanced equation, but must be determined from rate data. In contrasialieqetion quotent ean beqitten firectly from the balanced equation: $Q$ is a ratio made up of product concentration terms multiplied together and divided by reactant concentration terms multiplied together, with each term raised to the power of its stoichiometric coefficient in the balanced equation.

The most common form of the reaction quotient shows reactant and product terms as molar concentrations, which are designated by square brackets, [ ]. In the cases you've seen so far, $K$ is the equilibrium constant based on concentrations, designated from now on as $K_{\mathrm{c}}$. Similarly, we designate the reaction quotient based on concentrations as $Q_{\mathrm{c}}$. For the general balanced equation

$$
a \mathrm{~A}+b \mathrm{~B} \rightleftharpoons c \mathrm{C}+d \mathrm{D}
$$

where $a, b, c$, and $d$ are the stoichiometric coefficients, the reaction quotient is

$$
\begin{equation*}
Q_{\mathrm{c}}=\frac{[\mathrm{C}]^{c}[\mathrm{D}]^{d}}{[\mathrm{~A}]^{a}[\mathrm{~B}]^{b}} \tag{17.4}
\end{equation*}
$$

(Another form of the reaction quotient that we discuss later shows gaseous reactant and product terms as pressures.)

To construct the reaction quotient for any reaction, write the balanced equation first. For the formation of ammonia from its elements, for example, the balanced equation (with colored coefficients for easy reference) is

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
$$

To construct the reaction quotient, we place the product term in the numerator and the reactant terms in the denominator, multiplied by each other, and raise each term to the power of its balancing coefficient (colored as in the equation above):

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{NH}_{3}\right]^{2}}{\left[\mathrm{~N}_{2}\right]\left[\mathrm{H}_{2}\right]^{3}}
$$

Let's practice this essential skill.

## SAMPLE PROBLEM 17.1 Writing the Reaction Quotient

 from the Balanced EquationPROBLEM Write the reaction quotient, $Q_{\mathrm{c}}$, for each of the following reactions:
$(a)$ The decomposition of dinitrogen pentaoxide, $\mathrm{N}_{2} \mathrm{O}_{5}(g) \rightleftharpoons \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)$
(b) The combustion of propane gas, $\mathrm{C}_{3} \mathrm{H}_{8}(g)+\mathrm{O}_{2}(g) \rightleftharpoons \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)$

PLAN We balance the equations and then construct the reaction quotient (Equation 17.4).
SOLUTION (a) $2 \mathrm{~N}_{2} \mathrm{O}_{5}(g) \rightleftharpoons 4 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)$

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{NO}_{2}\right]^{4}\left[\mathrm{O}_{2}\right]}{\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]^{2}}
$$

(b) $\mathrm{C}_{3} \mathrm{H}_{8}(g)+5 \mathrm{O}_{2}(g) \rightleftharpoons 3 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(g)$

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{CO}_{2}\right]^{3}\left[\mathrm{H}_{2} \mathrm{O}\right]^{4}}{\left[\mathrm{C}_{3} \mathrm{H}_{8}\right]\left[\mathrm{O}_{2}\right]^{5}}
$$

CHECK Always be sure that the exponents in $Q$ are the same as the balancing coefficients. A good check is to reverse the process: turn the numerator into products and the denominator into reactants, and change the exponents to coefficients.
FOLLOW-UP PROBLEM 17.1 Write the reaction quotient, $Q_{\mathrm{c}}$, for each of the following reactions (unbalanced):
(a) The first step in nitric acid production, $\mathrm{NH}_{3}(g)+\mathrm{O}_{2}(g) \rightleftharpoons \mathrm{NO}(g)+\mathrm{H}_{2} \mathrm{O}(g)$
(b) The disproportionation of nitric oxide, $\mathrm{NO}(g) \rightleftharpoons \mathrm{N}_{2} \mathrm{O}(g)+\mathrm{NO}_{2}(g)$

## Variations in the Form of the Reaction Quotient

As you'll see in the upcoming discussion, the reaction quotient $Q$ is a collection
 Therefore, the value of $Q$, which varies during the reaction, and the value of $K$, which is the constant value that $Q$ attains when the system has reached equilibrium, also depend on how the balanced equation is written.
A Word about Units for $\mathbf{Q}$ and $\boldsymbol{K}$ In this text (and most others), the values of $Q$ and $K$ are shown as unitless numbers. This is because each term in the reaction quotient represents the ratio of the measured quantity of the substance (molar concentration or pressure) to the thermodynamic standard-state quantity of the substance. Recall from Section 6.6 that these standard states are $1 M$ for a substance in solution, 1 atm for gases, and the pure substance for a liquid or solid. Thus, a concentration of 1.20 M becomes $\frac{1.20 \mathrm{M}}{1 \mathrm{M}}=1.20$; similarly, a pressure of 0.53 atm becomes $\frac{0.53 \mathrm{~atm}}{1 \mathrm{~atm}}=0.53$. With these quantity terms unitless, the ratio of terms we use to find the value of $Q$ (or $K$ ) is also unitless.
Form of $Q$ for an Overall Reaction Notice that we've been writing reaction quotients without knowing whether an equation represents an individual reaction step or an overall multistep reaction. We can do this because we obtain the same expression for the overall reaction as we do when we combine the expressions for the individual steps. That is, if an overall reaction is the sum of two or more reactions, the overall reaction quotient (or equilibrium constant) is the product of the reaction quotients (or equilibrium constants) for the steps:

$$
Q_{\text {overall }}=Q_{1} \times Q_{2} \times Q_{3} \times \cdots
$$

and

$$
\begin{equation*}
K_{\text {overall }}=K_{1} \times K_{2} \times K_{3} \times \cdots \tag{17.5}
\end{equation*}
$$

Sample Problem 17.2 demonstrates this point.

## SAMPLE PROBLEM 17.2 Writing the Reaction Quotient and Finding $K$ for an Overall Reaction

PROBLEM Understanding reactions involving normal components of air is essential for solving problems dealing with atmospheric pollution. Here is a reaction sequence involving $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$, the most abundant gases in air. Nitrogen dioxide is a toxic pollutant that contributes to photochemical smog.
(1) $\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}(g)$

$$
K_{\mathrm{c} 1}=4.3 \times 10^{-25}
$$

(2) $2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}_{2}(g)$
(a) Show that the overall $Q_{\mathrm{c}}$ for this reaction sequence is the same as the product of the $Q_{\mathrm{c}}$ 's for the individual reactions.
(b) Given that the $K_{\mathrm{c}}$ 's occur at the same temperature, find $K_{\mathrm{c}}$ for the overall reaction.

PLAN (a) We first write the overall reaction by adding the individual reactions and then write the overall $Q_{\mathrm{c}}$. Next, we write the $Q_{\mathrm{c}}$ for each reaction. Because we $a d d$ the individual steps, we multiply their $Q_{\mathrm{c}}$ 's and cancel common terms to obtain the overall $Q_{\mathrm{c}}$.
(b) We are given the individual $K_{\text {c }}$ values $\left(4.3 \times 10^{-25}\right.$ and $\left.6.4 \times 10^{9}\right)$, so we multiply them to find $K_{\text {c(overall) }}$.
SOLUTION (a) Writing the overall reaction and its reaction quotient:

$$
\begin{gather*}
(1)  \tag{1}\\
\begin{array}{c}
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}_{( }(g) \\
\text { (2) } \\
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}_{2}(g) \\
\text { Overall: } \\
\mathrm{N}_{2}(g)+2 \mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}_{2}(g) \\
\\
Q_{\text {c(overall }}=\frac{\left[\mathrm{NO}_{2}\right]^{2}}{\left[\mathrm{~N}_{2}\right]\left[\mathrm{O}_{2}\right]^{2}}
\end{array}
\end{gather*}
$$

Writing the reaction quotients for the individual steps:
For step 1,

$$
Q_{\mathrm{cl}}=\frac{\left[\mathrm{NO}^{2}\right.}{\left[\mathrm{N}_{2}\right]\left[\mathrm{O}_{2}\right]}
$$

For step 2,

$$
Q_{\mathrm{c} 2}=\frac{\left[\mathrm{NO}_{2}\right]^{2}}{\left[\mathrm{NO}^{2}\left[\mathrm{O}_{2}\right]\right.}
$$

Multiplying the individual reaction quotients and canceling:

$$
Q_{\mathrm{c} 1} \times Q_{\mathrm{c} 2}=\frac{[\mathrm{NO}]^{2}}{\left[\mathrm{~N}_{2}\right]\left[\mathrm{O}_{2}\right]} \times \frac{\left[\mathrm{NO}_{2}\right]^{2}}{[\mathrm{NO}]^{2}\left[\mathrm{O}_{2}\right]}=\frac{\left[\mathrm{NO}_{2}\right]^{2}}{\left[\mathrm{~N}_{2}\right]\left[\mathrm{O}_{2}\right]^{2}}=Q_{\mathrm{c}(\text { overall })}
$$

(b) Calculating the overall $K_{\mathrm{c}}$ :

$$
K_{\mathrm{c}(\text { overall })}=K_{\mathrm{c} 1} \times K_{\mathrm{c} 2}=\left(4.3 \times 10^{-25}\right)\left(6.4 \times 10^{9}\right)=2.8 \times 10^{-15}
$$

CHECK Round off and check the calculation in part (b):

$$
K_{\mathrm{c}} \approx\left(4 \times 10^{-25}\right)\left(6 \times 10^{9}\right)=24 \times 10^{-16}=2.4 \times 10^{-15}
$$

FOLLOW-UP PROBLEM 17.2 The following sequence of individual steps has been proposed for the overall reaction between $\mathrm{H}_{2}$ and $\mathrm{Br}_{2}$ to form HBr :
(1) $\mathrm{Br}_{2}(g) \rightleftharpoons 2 \operatorname{Br}(g)$
(2) $\mathrm{Br}(g)+\mathrm{H}_{2}(g) \rightleftharpoons \mathrm{HBr}(g)+\mathrm{H}(g)$
(3) $\mathrm{H}(g)+\mathrm{Br}(g) \rightleftharpoons \mathrm{HBr}(g)$

Write the overall balanced equation and show that the overall $Q_{\mathrm{c}}$ is the product of the $Q_{\mathrm{c}}$ 's for the individual steps.

Form of $Q$ for a Forward and a Reverse Reaction The form of the reaction quotient depends on the direction in which the balanced equation is written. Consider, for example, the oxidation of sulfur dioxide to sulfur trioxide. This reaction is a key step in acid rain formation and sulfuric acid production. The balanced equation is

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{SO}_{3}(g)
$$

The reaction quotient for this equation as written is

$$
Q_{\mathrm{c}(\mathrm{fwd})}=\frac{\left[\mathrm{SO}_{3}\right]^{2}}{\left[\mathrm{SO}_{2}\right]^{2}\left[\mathrm{O}_{2}\right]}
$$

If we had written the reverse reaction, the decomposition of sulfur trioxide,

$$
2 \mathrm{SO}_{3}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{SO}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})
$$

the reaction quotient would be the reciprocal of $Q_{\mathrm{c}(\mathrm{fwd})}$ :

$$
Q_{\mathrm{c}(\mathrm{rev})}=\frac{\left[\mathrm{SO}_{2}\right]^{2}\left[\mathrm{O}_{2}\right]}{\left[\mathrm{SO}_{3}\right]^{2}}=\frac{1}{Q_{\mathrm{c}(\mathrm{fwd})}}
$$

Thus, a reaction quotient (or equilibrium constant) for a forward reaction is the reciprocal of the reaction quotient (or equilibrium constant) for the reverse reaction:

$$
\begin{equation*}
Q_{\mathrm{c}(\mathrm{fwd})}=\frac{1}{Q_{\mathrm{c}(\mathrm{rev})}} \quad \text { and } \quad K_{\mathrm{c}(\mathrm{fwd})}=\frac{1}{K_{\mathrm{c}(\mathrm{rev})}} \tag{17.6}
\end{equation*}
$$

The $K_{\mathrm{c}}$ values for the forward and reverse reactions at 1000 K are

$$
K_{\mathrm{c}(\mathrm{fwd})}=261 \quad \text { and } \quad K_{\mathrm{c}(\mathrm{rev})}=\frac{1}{K_{\mathrm{c}(\mathrm{fwd})}}=\frac{1}{261}=3.83 \times 10^{-3}
$$

These values make sense: if the forward reaction goes far to the right (high $K_{\mathrm{c}}$ ), the reverse reaction does not (low $K_{\mathrm{c}}$ ).
Form of $Q$ for a Reaction with Coefficients Multiplied by a Common Factor
Multiplying all the coefficients of the equation by some factor also changes the form of $Q$. For example, multiplying all the coefficients in the equation for the formation of $\mathrm{SO}_{3}$ (bottom of p. 744) by $\frac{1}{2}$ gives

$$
\begin{aligned}
& \mathrm{SO}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \\
& \text { action quotient is } \\
& \mathrm{SO}_{3}(\mathrm{~g}) \mathrm{F}
\end{aligned}
$$

$$
Q_{\mathrm{c}(\mathrm{fwd})}^{\prime}=\frac{\left[\mathrm{SO}_{3}\right]}{\left[\mathrm{SO}_{2}\right]\left[\mathrm{O}_{2}\right]^{1 / 2}}
$$

Notice that $Q_{\mathrm{c}}$ for the halved equation equals $Q_{\mathrm{c}}$ for the original equation raised to the $\frac{1}{2}$ power:

$$
Q_{\mathrm{c}(\mathrm{fwd})}^{\prime}=Q_{\mathrm{c}(\mathrm{fwd})}^{1 / 2}=\left(\frac{\left[\mathrm{SO}_{3}\right]^{2}}{\left[\mathrm{SO}_{2}\right]^{2}\left[\mathrm{O}_{2}\right]}\right)^{1 / 2}=\frac{\left[\mathrm{SO}_{3}\right]}{\left[\mathrm{SO}_{2}\right]\left[\mathrm{O}_{2}\right]^{1 / 2}}
$$

Once again, the same property holds for the equilibrium constants. Relating the halved reaction to the original, we have

$$
K_{\mathrm{c}(\mathrm{fwd})}^{\prime}=K_{\mathrm{c}(\mathrm{fwd})}^{1 / 2}=(261)^{1 / 2}=16.2
$$

Similarly, if you double coefficients, the reaction quotient is the original expression squared; if you triple coefficients, it is the original expression cubed; and so on. It may seem that we have changed the extent of the reaction, as indicated by a change in $K$, merely by changing the balancing coefficients of the equation, but this clearly cannot be true. A particular $K$ has meaning only in relation to a particular balanced equation. In this case, $K_{\mathrm{c}(\mathrm{fwd})}$ and $K_{\mathrm{c}(\mathrm{fwd})}^{\prime}$ relate to different equations and thus cannot be compared directly.

In general, if all the coefficients of the balanced equation are multiplied by some factor, that factor becomes the exponent for relating the reaction quotients and the equilibrium constants. For a multiplying factor $n$, which we can write as

$$
n(a \mathrm{~A}+b \mathrm{~B} \rightleftharpoons c \mathrm{C}+d \mathrm{D})
$$

the reaction quotient and equilibrium constant are

$$
\begin{equation*}
Q^{\prime}=Q^{n}=\left(\frac{[\mathrm{C}]^{c}[\mathrm{D}]^{d}}{[\mathrm{~A}]^{a}[\mathrm{~B}]^{b}}\right)^{n} \quad \text { and } \quad K^{\prime}=K^{n} \tag{17.7}
\end{equation*}
$$

## SAMPLE PROBLEM 17.3 Finding the Equilibrium Constant for an

 Equation Multiplied by a Common FactorPROBLEM For the ammonia-formation reaction,

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
$$

the equilibrium constant, $K_{\mathrm{c}}$, is $2.4 \times 10^{-3}$ at 1000 K . If we change the coefficients of this equation, which we'll call the reference (ref) equation, what are the values of $K_{\mathrm{c}}$ for the following balanced equations?
(a) $\frac{1}{3} \mathrm{~N}_{2}(g)+\mathrm{H}_{2}(g) \rightleftharpoons \frac{2}{3} \mathrm{NH}_{3}(g)$
(b) $\mathrm{NH}_{3}(g) \rightleftharpoons \frac{1}{2} \mathrm{~N}_{2}(g)+\frac{3}{2} \mathrm{H}_{2}(g)$

PLAN We compare each equation with the reference equation to see how the direction and coefficients have changed. (a) The equation is the reference equation multiplied by $\frac{1}{3}$, so $K_{\mathrm{c}}$ equals $K_{\mathrm{c}(\text { ref })}\left(2.4 \times 10^{-3}\right)$ raised to the $\frac{1}{3}$ power. (b) The equation is one-half the reverse of the reference equation, so $K_{\mathrm{c}}$ is the reciprocal of $K_{\mathrm{c}(\text { ref })}$ raised to the $\frac{1}{2}$ power.
SOLUTION The reaction quotient for the reference equation is $Q_{\mathrm{c}(\text { ref })}=\frac{\left[\mathrm{NH}_{3}\right]^{2}}{\left[\mathrm{~N}_{2}\right]\left[\mathrm{H}_{2}\right]^{3}}$.
(a)

$$
Q_{\mathrm{c}}=Q_{\mathrm{c}(\mathrm{ref})}^{1 / 3}=\left(\frac{\left[\mathrm{NH}_{3}\right]^{2}}{\left[\mathrm{~N}_{2}\right]\left[\mathrm{H}_{2}\right]^{3}}\right)^{1 / 3}=\frac{\left[\mathrm{NH}_{3}\right]^{2 / 3}}{\left[\mathrm{~N}_{2}\right]^{1 / 3}\left[\mathrm{H}_{2}\right]}
$$

Thus,

$$
K_{\mathrm{c}}=K_{\mathrm{c}(\mathrm{ref})}^{1 / 3}=\left(2.4 \times 10^{-3}\right)^{1 / 3}=0.13
$$

(b)

$$
Q_{\mathrm{c}}=\left(\frac{1}{Q_{\mathrm{c}(\mathrm{ref})}}\right)^{1 / 2}=\left(\frac{\frac{1}{\left[\mathrm{NH}_{3}\right]^{2}}}{\left[\mathrm{~N}_{2}\right]\left[\mathrm{H}_{2}\right]^{3}}\right)^{1 / 2}=\frac{\left[\mathrm{N}_{2}\right]^{1 / 2}\left[\mathrm{H}_{2}\right]^{3 / 2}}{\left[\mathrm{NH}_{3}\right]}
$$

Thus,

$$
K_{\mathrm{c}}=\left(\frac{1}{K_{\mathrm{c}(\mathrm{ref})}}\right)^{1 / 2}=\left(\frac{1}{2.4 \times 10^{-3}}\right)^{1 / 2}=20
$$

CHECK A good check is to work the math backward. (a) $(0.13)^{3}=2.2 \times 10^{-3}$, within rounding of $2.4 \times 10^{-3}$. The reaction goes in the same direction, so at equilibrium, there should be mostly reactants, as $K_{\mathrm{c}}<1$ indicates. (b) $1 /(20 .)^{2}=2.5 \times 10^{-3}$, again within rounding. At equilibrium, the reverse reaction should yield mostly products, as $K_{\mathrm{c}}>1$ indicates.
FOLLOW-UP PROBLEM 17.3 At 1200 K , the reaction of hydrogen and chlorine to form hydrogen chloride is

$$
\mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g) \rightleftharpoons 2 \mathrm{HCl}(g) \quad K_{\mathrm{c}}=7.6 \times 10^{8}
$$

Calculate $K_{\text {c }}$ for the following reactions:
(a) $\frac{1}{2} \mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{Cl}_{2}(g) \rightleftharpoons \mathrm{HCl}(g)$
(b) $\frac{4}{3} \mathrm{HCl}(g) \rightleftharpoons \frac{2}{3} \mathrm{H}_{2}(g)+\frac{2}{3} \mathrm{Cl}_{2}(g)$

Form of $Q$ for a Reaction Involving Pure Liquids and Solids Until now, we've looked at homogeneous equilibria, systems in which all the components of the reaction are in the same phase, such as a system of reacting gases. When the components are in different phases, the system reaches heterogeneous equilibrium.

Consider the decomposition of limestone to lime and carbon dioxide, in which a gas and two solids make up the reaction components:

$$
\mathrm{CaCO}_{3}(s) \rightleftharpoons \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

Based on the rules for writing the reaction quotient, we have

$$
Q_{\mathrm{c}}=\frac{[\mathrm{CaO}]\left[\mathrm{CO}_{2}\right]}{\left[\mathrm{CaCO}_{3}\right]}
$$

A pure solid, however, such as $\mathrm{CaCO}_{3}$ or CaO , always has the same "concentration" at a given temperature, that is, the same number of moles per liter of solid, just as it has the same density $\left(\mathrm{g} / \mathrm{cm}^{3}\right)$. Therefore, the concentration of a pure solid is constant, as is the concentration of a pure liquid (but not that of a dissolved solute).

Figure 17.4 The reaction quotient for a heterogeneous system. Even though the two containers have different amounts of the two solids CaO and $\mathrm{CaCO}_{3}$, as long as both solids are present, at a given temperature, the containers have the same $\left[\mathrm{CO}_{2}\right]$ at equilibrium.

Because we are concerned only with concentrations that change as they approach equilibrium, we eliminate the terms for pure liquids and solids from the reaction quotient. We do this by multiplying both sides of the above equation by $\left[\mathrm{CaCO}_{3}\right]$ and dividing both sides by $[\mathrm{CaO}]$ and get a new reaction quotient, $Q_{\mathrm{c}}^{\prime}$. Thus, the only substance whose concentration can change is the gas $\mathrm{CO}_{2}$ :

$$
Q_{\mathrm{c}}^{\prime}=Q_{\mathrm{c}} \frac{A\left[\mathrm{CaOB}_{3}\right]}{[\mathrm{CaO}]}=\left[\mathrm{CO}_{2}\right] \text { Fnhancer }
$$

No matter how much CaO and $\mathrm{CaCO}_{3}$ are in the reaction vessel, as long as some of each is present, the reaction quotient for the reaction equals the $\mathrm{CO}_{2}$ concentration (Figure 17.4).

Table 17.2 summarizes the ways of writing $Q$ and calculating $K$.

## Table 17.2 Ways of Expressing $Q$ and Calculating $K$

| Form of Chemical Equation | Form of $Q$ | Value of $K$ |
| :---: | :---: | :---: |
| Reference reaction: $\mathrm{A} \rightleftharpoons \mathrm{B}$ | $Q_{(\mathrm{ref})}=\frac{[\mathrm{B}]}{[\mathrm{A}]}$ | $K_{(\mathrm{ref})}=\frac{[\mathrm{B}]_{\mathrm{eq}}}{[\mathrm{~A}]_{\mathrm{eq}}}$ |
| Reverse reaction: $\mathrm{B} \rightleftharpoons \mathrm{A}$ | $Q=\frac{1}{Q_{(\mathrm{ref})}}=\frac{[\mathrm{A}]}{[\mathrm{B}]}$ | $K=\frac{1}{K_{\text {(ref) }}}$ |
| Reaction as sum of two steps: <br> (1) $A \rightleftharpoons C$ | $Q_{1}=\frac{[\mathrm{C}]}{[\mathrm{A}]} ; Q_{2}=\frac{[\mathrm{B}]}{[\mathrm{C}]}$ |  |
| $(2) \mathrm{C} \rightleftharpoons \mathrm{B}$ | $\begin{aligned} Q_{\text {overall }} & =Q_{1} \times Q_{2}=Q_{(\mathrm{ref})} \\ & =\frac{[\mathrm{C}]}{[\mathrm{A}]} \times \frac{[\mathrm{B}]}{[\mathrm{C}]}=\frac{[\mathrm{B}]}{[\mathrm{A}]} \end{aligned}$ | $\begin{aligned} K_{\text {overall }} & =K_{1} \times K_{2} \\ & =K_{(\text {ref })} \end{aligned}$ |
| Coefficients multiplied by $n$ | $Q=Q_{\text {(ref) }}^{n}$ | $K=K_{(\text {ref })}^{n}$ |
| Reaction with pure solid or liquid component, such as $\mathrm{A}(s)$ | $Q=Q_{(\text {(ref })}[\mathrm{A}]=[\mathrm{B}]$ | $K=K_{(\text {ref })}[\mathrm{A}]=[\mathrm{B}]$ |

## Section Summary

The reaction quotient, $Q$, is a particular ratio of product to reactant terms. Substituting experimental values into this expression gives the value of $Q$, which changes as the reaction proceeds. When the system reaches equilibrium at a particular temperature, $Q=K$. • If a reaction is the sum of two or more steps, the overall $Q$ (or $K$ ) is the product of the individual Q's (or K's). - The form of Q is based directly on the balanced equation for the reaction exactly as written, so it changes if the equation is reversed or multiplied by some factor, and $K$ changes accordingly. - Pure liquids or solids do not appear in the expression for $Q$ because their concentrations are constant.

### 17.3 EXPRESSING EQUILIBRIA WITH PRESSURE TERMS: RELATION BETWEEN $K_{c}$ and $K_{p}$

It is easier to measure the pressure of a gas than its concentration and, as long as the gas behaves nearly ideally under the conditions of the experiment, the ideal gas law (Section 5.3) allows us to relate these variables to each other:

$$
P V=n R T, \quad \text { so } \quad P=\frac{n}{V} R T \quad \text { or } \quad \frac{P}{R T}=\frac{n}{V}
$$

where $P$ is the pressure of a gas and $n / V$ is its molar concentration $(M)$. Thus, with $R$ a constant and if $T$ is kept constant, pressure is directly proportional to molar concentration. When the substances in the reaction are gases, we can express the reaction quotient and calculate its value in terms of partial pressures instead of concentrations. For example, in the reaction between gaseous NO and $\mathrm{O}_{2}$,

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}_{2}(g)
$$

the reaction quotient based on partial pressures, $Q_{\mathrm{p}}$, is

## 

(In later chapters, you'll see cases where some reaction components are expressed as concentrations and others as partial pressures.) The equilibrium constant obtained when all components are present at their equilibrium partial pressures is designated $K_{\mathrm{p}}$, the equilibrium constant based on pressures. In many cases, $K_{\mathrm{p}}$ has a value different from $K_{\mathrm{c}}$, but if you know one, you can calculate the other by noting the change in amount ( mol ) of gas, $\Delta n_{\text {gas }}$, from the balanced equation. Let's see this relationship by converting the terms in $Q_{\mathrm{c}}$ for the reaction of NO and $\mathrm{O}_{2}$ to those in $Q_{\mathrm{p}}$ :

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}_{2}(g)
$$

As the balanced equation shows,
$3 \mathrm{~mol}(2 \mathrm{~mol}+1 \mathrm{~mol})$ gaseous reactants $\rightleftharpoons 2 \mathrm{~mol}$ gaseous products
With $\Delta$ meaning final minus initial (products minus reactants), we have
$\Delta n_{\text {gas }}=$ moles of gaseous product - moles of gaseous reactant $=2-3=-1$
Keep this value of $\Delta n_{\text {gas }}$ in mind because it appears in the algebraic conversion that follows. The reaction quotient based on concentrations is

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{NO}_{2}\right]^{2}}{[\mathrm{NO}]^{2}\left[\mathrm{O}_{2}\right]}
$$

Rearranging the ideal gas law to $n / V=P / R T$, we express concentrations as $n / V$ and convert them to partial pressures, $P$; then we collect the $R T$ terms and cancel:

$$
Q_{\mathrm{c}}=\frac{\frac{n_{\mathrm{NO}_{2}}^{2}}{V^{2}}}{\frac{n_{\mathrm{NO}}^{2}}{V^{2}} \times \frac{P_{\mathrm{N}_{2}}^{2}}{V}}=\frac{\frac{1}{(R T)^{2}}}{\frac{P_{\mathrm{NO}}^{2}}{(R T)^{2}} \times \frac{P_{\mathrm{O}_{2}}}{R T}}=\frac{P_{\mathrm{NO}_{2}}^{2}}{P_{\mathrm{NO}}^{2} \times P_{\mathrm{O}_{2}}} \times \frac{\frac{1}{(R T)^{2}}}{\frac{1}{(R T)^{2}} \times \frac{1}{R T}}=\frac{P_{\mathrm{NO}_{2}}^{2}}{P_{\mathrm{NO}}^{2} \times P_{\mathrm{O}_{2}}} \times R T
$$

The far right side of the previous expression is $Q_{\mathrm{p}}$ multiplied by $R T$ : $Q_{\mathrm{c}}=Q_{\mathrm{p}}(R T)$. Also, at equilibrium, $K_{\mathrm{c}}=K_{\mathrm{p}}(R T)$; thus, $K_{\mathrm{p}}=\frac{K_{\mathrm{c}}}{R T}$, or $K_{\mathrm{c}}(R T)^{-1}$.

Notice that the exponent of the RT term equals the change in the amount (mol) of gas $\left(\Delta n_{g a s}\right)$ from the balanced equation, -1 . Thus, in general,

$$
\begin{equation*}
K_{\mathrm{p}}=K_{\mathrm{c}}(R T)^{\Delta n_{\mathrm{gas}}} \tag{17.8}
\end{equation*}
$$

The units generally used for the partial pressure terms in $K_{\mathrm{p}}$ are atmospheres, pascals, or torr, raised to some power, and the units of $R$ must be consistent with those units. As Equation 17.8 shows, for those reactions in which the amount (mol) of gas does not change, we have $\Delta n_{\text {gas }}=0$, so the $R T$ term drops out and $K_{\mathrm{p}}=K_{\mathrm{c}}$.

## SAMPLE PROBLEM 17.4 Converting Between $K_{\mathrm{c}}$ and $K_{\mathrm{p}}$

PROBLEM A chemical engineer injects limestone $\left(\mathrm{CaCO}_{3}\right)$ into the hot flue gas of a coalburning power plant to form lime $(\mathrm{CaO})$, which scrubs $\mathrm{SO}_{2}$ from the gas and forms gypsum $\left(\mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}\right)$. Find $K_{\mathrm{c}}$ for the following reaction, if $\mathrm{CO}_{2}$ pressure is in atmospheres:

$$
\mathrm{CaCO}_{3}(s) \rightleftharpoons \mathrm{CaO}(s)+\mathrm{CO}_{2}(g) \quad K_{\mathrm{p}}=2.1 \times 10^{-4}(\text { at } 1000 . \mathrm{K})
$$

PLAN We know $K_{\mathrm{p}}\left(2.1 \times 10^{-4}\right)$, so to convert between $K_{\mathrm{p}}$ and $K_{\mathrm{c}}$, we must first determine $\Delta n_{\text {gas }}$ from the balanced equation. Then we rearrange Equation 17.8. With gas pressure in atmospheres, $R$ is $0.0821 \mathrm{~atm} \cdot \mathrm{~L} / \mathrm{mol} \cdot \mathrm{K}$.
SOLUTION Determining $\Delta n_{\text {gas }}$ : There is 1 mol of gaseous product and no gaseous reactant, so $\Delta n_{\text {gas }}=1-0=1$.
Rearranging Equation 17.8 and calculating $K_{\mathrm{c}}$ :

$$
K_{\mathrm{p}}=K_{\mathrm{c}}(R T)^{1}
$$

so

$$
\begin{aligned}
K_{\mathrm{c}} & =K_{\mathrm{p}}(R T)^{-1} \\
& =\left(2.1 \times 10^{-4}\right)(0.0821 \times 1000 .)^{-1} \\
& =2.6 \times 10^{-6}
\end{aligned}
$$

CHECK Work backward to see whether you obtain the given $K_{\mathrm{p}}$ :

$$
\begin{aligned}
K_{\mathrm{p}} & =\left(2.6 \times 10^{-6}\right)(0.0821 \times 1000 .) \\
& =2.1 \times 10^{-4}
\end{aligned}
$$

FOLLOW-UP PROBLEM 17.4 Calculate $K_{\mathrm{p}}$ for the following reaction:

$$
\mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g) \rightleftharpoons \mathrm{PCl}_{5}(g) \quad K_{\mathrm{c}}=1.67(\text { at } 500 . \mathrm{K})
$$

## Section Summary

The reaction quotient and the equilibrium constant are most often expressed in terms of concentrations ( $Q_{c}$ and $K_{c}$ ). For gases, they can also be expressed in terms of partial pressures $\left(Q_{\mathrm{p}}\right.$ and $\left.K_{\mathrm{p}}\right)$. - The values of $K_{\mathrm{p}}$ and $K_{\mathrm{c}}$ are related by a derivation that relies on the ideal gas law: $K_{\mathrm{p}}=K_{\mathrm{c}}(R T)^{\Delta n_{\text {gas }}}$.

### 17.4 REACTION DIRECTION: COMPARING Q and $K$

Suppose you start a reaction with a mixture of reactants and products and you know the equilibrium constant at the temperature of the reaction. How do you know if the reaction has reached equilibrium? By comparing the value of $Q$ at a particular time with the known $K$, you can tell whether the reaction has attained equilibrium or, if not, in which direction it is progressing. With product terms in the numerator of $Q$ and reactant terms in the denominator, more product makes $Q$ larger, and more reactant makes $Q$ smaller.

Figure 17.5 Reaction direction and the relative sizes of $Q$ and $K$. When $Q_{c}$ is smaller than $K_{c}$, the equilibrium of the reaction system shifts to the right, that is, toward products. When $Q_{c}$ is larger than $K_{\mathrm{c}}$, the equilibrium of the reaction system shifts to the left. Both shifts continue until $Q_{\mathrm{c}}=K_{\mathrm{c}}$. Note that the size of $K_{\mathrm{c}}$ remains the same throughout.

The three possible relative sizes of $Q$ and $K$ are shown in Figure 17.5.

- $Q<K$. If the value of $Q$ is smaller than $K$, the denominator (reactants) is large relative to the numerator (products). For $Q$ to become equal to $K$, the reactants must decrease and the products increase. In other words, the reaction will progress to the right, toward products, until equilibrium is reached:

$$
\text { If } Q<K \text {, reactants } \longrightarrow \text { products }
$$

- Aqpakg $Q$ B Dader thank hemareafor (products) will decrease and the denominator (reactants) increase until equilibrium is reached. Therefore, the reaction will progress to the left, toward reactants:

$$
\text { If } Q>K \text {, reactants } \longleftarrow \text { products }
$$

- $Q=K$. This situation exists only when the reactant and product concentrations (or pressures) have attained their equilibrium values. Thus, despite the processes continuing at the molecular level, no further net change appears:

$$
\text { If } Q=K \text {, reactants } \rightleftharpoons \text { products }
$$

The next two sample problems focus on this idea: the first relies on molecular scenes and the second on concentration data to determine reaction direction.

## SAMPLE PROBLEM 17.5 Using Molecular Scenes to Determine Reaction Direction

PROBLEM During one run of the reaction $\mathrm{A}(g) \rightleftharpoons \mathrm{B}(g)$, the equilibrium mixture at $175^{\circ} \mathrm{C}$ had the following composition: $[\mathrm{A}]=2.8 \times 10^{-4} \mathrm{M}$ and $[\mathrm{B}]=1.2 \times 10^{-4} \mathrm{M}$. The molecular scenes below represent mixtures at various times during runs $1-4$ of the reaction at $175^{\circ} \mathrm{C}$ (A is red; B is blue). In which direction does the reaction shift for each mixture to reach equilibrium?

PLAN We must compare $Q_{\mathrm{c}}$ with $K_{\mathrm{c}}$ to determine the reaction direction, so we first use the given equilibrium concentrations to find $K_{\mathrm{c}}$. Then we count spheres and calculate $Q_{\mathrm{c}}$ for each mixture. If $Q_{\mathrm{c}}<K_{\mathrm{c}}$, the reaction shifts to the right (reactants to products); if $Q_{\mathrm{c}}>$ $K_{\mathrm{c}}$, the reaction shifts to the left (products to reactants); and if $Q_{\mathrm{c}}=K_{\mathrm{c}}$, there is no change. SOLUTION Writing the reaction quotient and using the data to find $K_{\mathrm{c}}$ :

$$
Q_{\mathrm{c}}=\frac{[\mathrm{B}]}{[\mathrm{A}]}=\frac{1.2 \times 10^{-4}}{2.8 \times 10^{-4}}=0.43=K_{\mathrm{c}}
$$

Counting red (A) and blue (B) spheres to calculate $Q_{\mathrm{c}}$ for each mixture:

1. $Q_{\mathrm{c}}=8 / 2=4.0$
2. $Q_{\mathrm{c}}=3 / 7=0.43$
3. $Q_{\mathrm{c}}=4 / 6=0.67$
4. $Q_{\mathrm{c}}=2 / 8=0.25$

Comparing $Q_{\mathrm{c}}$ with $K_{\mathrm{c}}$ to determine reaction direction:

1. $Q_{\mathrm{c}}>K_{\mathrm{c}}$ : left
2. $Q_{\mathrm{c}}=K_{\mathrm{c}}$ : no change
3. $Q_{\mathrm{c}}>K_{\mathrm{c}}:$ left
4. $Q_{\mathrm{c}}<K_{\mathrm{c}}$ : right

CHECK Making an error in the calculation for $K_{\mathrm{c}}$ would lead to incorrect conclusions throughout, so check that step: the exponents are the same, and $1.2 / 2.8$ is a bit less than 0.5 , as is the calculated $K_{\mathrm{c}}$. You can check the final answers by inspection; for example, for the number of $B$ (8) in mixture 1 to equal the number at equilibrium (3), more B must change to A , so the reaction must shift to the left.
FOLLOW-UP PROBLEM 17.5 At 338 K , the reaction $\mathrm{X}(\mathrm{g}) \rightleftharpoons \mathrm{Y}(\mathrm{g})$ has a $K_{\mathrm{c}}$ of 1.4. The scenes below represent different mixtures at 338 K , with X orange and Y green. In which direction does the reaction shift (if at all) for each mixture to reach equilibrium?

## Apago PDF Enhancer

## SAMPLE PROBLEM 17.6 Comparing $Q$ and $K$ to Determine

 Reaction DirectionPROBLEM For the reaction $\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftharpoons 2 \mathrm{NO}_{2}(g), K_{\mathrm{c}}=0.21$ at $100^{\circ} \mathrm{C}$. At a point during the reaction, $\left[\mathrm{N}_{2} \mathrm{O}_{4}\right]=0.12 \mathrm{M}$ and $\left[\mathrm{NO}_{2}\right]=0.55 \mathrm{M}$. Is the reaction at equilibrium? If not, in which direction is it progressing?
PLAN We write the expression for $Q_{\mathrm{c}}$, find its value by substituting the given concentrations, and then compare its value with the given $K_{\mathrm{c}}$.
SOLUTION Writing the reaction quotient and solving for $Q_{\mathrm{c}}$ :

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{NO}_{2}\right]^{2}}{\left[\mathrm{~N}_{2} \mathrm{O}_{4}\right]}=\frac{0.55^{2}}{0.12}=2.5
$$

With $Q_{\mathrm{c}}>K_{\mathrm{c}}$, the reaction is not at equilibrium and will proceed to the left until $Q_{\mathrm{c}}=K_{\mathrm{c}}$. CHECK With $\left[\mathrm{NO}_{2}\right]>\left[\mathrm{N}_{2} \mathrm{O}_{4}\right]$, we expect to obtain a value for $Q_{\mathrm{c}}$ that is greater than 0.21 . If $Q_{\mathrm{c}}>K_{\mathrm{c}}$, the numerator will decrease and the denominator will increase until $Q_{\mathrm{c}}=K_{\mathrm{c}}$; that is, this reaction will proceed toward reactants.
FOLLOW-UP PROBLEM 17.6 Chloromethane forms by the reaction

$$
\mathrm{CH}_{4}(g)+\mathrm{Cl}_{2}(g) \rightleftharpoons \mathrm{CH}_{3} \mathrm{Cl}(g)+\mathrm{HCl}(g)
$$

At $1500 \mathrm{~K}, K_{\mathrm{p}}=1.6 \times 10^{4}$. In the reaction mixture, $P_{\mathrm{CH}_{4}}=0.13 \mathrm{~atm}, P_{\mathrm{Cl}_{2}}=0.035 \mathrm{~atm}$, $P_{\mathrm{CH}_{3} \mathrm{Cl}}=0.24 \mathrm{~atm}$, and $P_{\mathrm{HCl}}=0.47 \mathrm{~atm}$. Is $\mathrm{CH}_{3} \mathrm{Cl}$ or $\mathrm{CH}_{4}$ forming?

## Section Summary

We compare the values of $Q$ and $K$ to determine the direction in which a reaction will proceed toward equilibrium.

- If $Q_{\mathrm{c}}<K_{\mathrm{c}}$, more product forms.
- If $Q_{\mathrm{c}}>K_{\mathrm{c}}$, more reactant forms.
- If $Q_{c}=K_{c}$, there is no net change.

### 17.5 HOW TO SOLVE EQUILIBRIUM PROBLEMS

As you've seen in previous sections, three criteria define a system at equilibrium:

- Reactant and product concentrations are constant over time.
- The forward reaction rate equals the reverse reaction rate.
- The reaction quotient equals the equilibrium constant: $Q=K$.

Now, let's apply equilibrium principles quantitatively. Many kinds of equilibrium problems arise in the real world-as well as on chemistry exams-but we can group most of them into two types:

1. We are given equilibrium quantities (concentrations or partial pressures) and solve for $K$.
2. We are given $K$ and initial quantities and solve for the equilibrium quantities.

## Using Quantities to Determine the Equilibrium Constant

There are two common variations on the type of equilibrium problem in which we solve for $K$ : one involves a straightforward substitution of quantities, and the other requires first finding some of the quantities.
Substituting Given Equilibrium Quantities into $Q$ to Find $K$ In the straightforward case, we are given the equilibrium quantities and we must calculate $K$.

Suppose, for example, that equal amounts of gaseous hydrogen and iodine are injected into a $1.50-\mathrm{L}$ reaction flask at a fixed temperature. In time, the following equilibrium is attained:

$$
\mathrm{H}_{2}(\mathrm{~g})+\mathrm{I}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{HI}(\mathrm{~g})
$$

At equilibrium, analysis shows that the flask contains 1.80 mol of $\mathrm{H}_{2}, 1.80 \mathrm{~mol}$ of $\mathrm{I}_{2}$, and 0.520 mol of $\mathrm{HL}_{\text {, }} \mathrm{We}$ calculate $K_{c}$ by finding the concentrations and stositurig thenfint the reation quoten? Given the balanced equation, we then write the reaction quotient:

$$
Q_{\mathrm{c}}=\frac{[\mathrm{HI}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{I}_{2}\right]}
$$

We first have to convert the amounts (mol) to concentrations (mol/L), using the flask volume of 1.50 L :

$$
\left[\mathrm{H}_{2}\right]=\frac{1.80 \mathrm{~mol}}{1.50 \mathrm{~L}}=1.20 \mathrm{M}
$$

Similarly, $\left[\mathrm{I}_{2}\right]=1.20 \mathrm{M}$, and $[\mathrm{HI}]=0.347 \mathrm{M}$. Substituting these values into the expression for $Q_{\mathrm{c}}$ gives $K_{\mathrm{c}}$ :

$$
K_{\mathrm{c}}=\frac{(0.347)^{2}}{(1.20)(1.20)}=8.36 \times 10^{-2}
$$

Using a Reaction Table to Determine Equilibrium Quantities and Find $K$ When some quantities are not given, we determine them first from the reaction stoichiometry and then find $K$. In the following example, pay close attention to a valuable tool being applied: the reaction table.

In a study of carbon oxidation, an evacuated vessel containing a small amount of powdered graphite is heated to 1080 K , and then $\mathrm{CO}_{2}$ is added to a pressure of 0.458 atm . Once the $\mathrm{CO}_{2}$ is added, the system starts to produce CO. After equilibrium has been reached, the total pressure inside the vessel is 0.757 atm . Calculate $K_{\mathrm{p}}$.

As always, we start to solve the problem by writing the balanced equation and the reaction quotient:

$$
\mathrm{CO}_{2}(\mathrm{~g})+\mathrm{C}(\text { graphite }) \rightleftharpoons 2 \mathrm{CO}(\mathrm{~g})
$$

The data are given in atmospheres and we must find $K_{\mathrm{p}}$, so we write $Q$ in terms of partial pressures (note the absence of a term for the solid, C):

$$
Q_{\mathrm{p}}=\frac{P_{\mathrm{CO}}^{2}}{P_{\mathrm{CO}_{2}}}
$$

We are given the initial $P_{\mathrm{CO}_{2}}$ and $P_{\text {total }}$ at equilibrium. To find $K_{\mathrm{p}}$, we must find the equilibrium pressures of $\mathrm{CO}_{2}$ and CO , which requires solving a stoichiometry problem, and then substitute them into the expression for $Q_{\mathrm{p}}$.

Let's think through what happened in the vessel. An unknown portion of the $\mathrm{CO}_{2}$ reacted with graphite to form an unknown amount of CO. We already know the relative amounts of $\mathrm{CO}_{2}$ and CO from the balanced equation: for each mole of $\mathrm{CO}_{2}$ that reacts, 2 mol of CO forms, which means that when $x \mathrm{~atm}$ of $\mathrm{CO}_{2}$ reacts, $2 x \mathrm{~atm}$ of CO forms:

$$
x \operatorname{atm~} \mathrm{CO}_{2} \longrightarrow 2 x \mathrm{~atm} \mathrm{CO}
$$

From the data given, we can predict something about the size of $K_{\mathrm{p}}$. If it were very large, almost all the $\mathrm{CO}_{2}$ would be converted to CO , so the final (total) pressure would be twice the initial pressure [ $2(0.458 \mathrm{~atm}) \approx 0.9 \mathrm{~atm}]$. On the other hand, if $K_{\mathrm{p}}$ were very small, almost no CO would form, so the final pressure would be close to the initial pressure, 0.458 atm . However, the final pressure $(0.757 \mathrm{~atm})$ is between these extremes, so $K_{\mathrm{p}}$ must have an intermediate value. The pressure of $\mathrm{CO}_{2}$ at equilibrium, $P_{\mathrm{CO}_{2}(\text { eq })}$, is the initial pressure, $P_{\mathrm{CO}_{2} \text { (init) }}$, minus the change in $\mathrm{CO}_{2}$ pressure, $x$, that is, the $\mathrm{CO}_{2}$ that reacts:

$$
P_{\mathrm{CO}_{2} \text { (init) }}-x=P_{\mathrm{CO}_{2}(\mathrm{eq})}
$$

Similarly, the pressure of CO at equilibrium, $P_{\mathrm{CO}(\mathrm{eq})}$, is the initial pressure, $P_{\mathrm{CO} \text { (init) }}$, plus the change in CO pressure, which is the CO that forms, $2 x$. Because $P_{\mathrm{CO} \text { (init) }}$ is zero at the beginning of the reaction, we have

$$
P_{\mathrm{CO}(\text { init })}+2 x=0+2 x=2 x=P_{\mathrm{CO}(\mathrm{eq})}
$$

To summarize this information, we'll use a reaction table similar to those in Chapter 3. It shows the balanced equation and what we know about

- the initial quantities (concentrations or pressures) of reactants and products
- the changes in these quantities durigethecracipr Enhancer
- the equilibrium quantities

| Pressure (atm) | $\mathbf{C O}_{\mathbf{2}}(\mathbf{g})$ | + | $\mathbf{C}($ graphite $)$ | $\rightleftharpoons$ |
| :--- | :---: | :---: | :---: | :---: |
| Initial | 0.458 | - |  | $\mathbf{2 C O}(\boldsymbol{g})$ |
| Change | $-x$ | - | 0 |  |
| Equilibrium | $0.458-x$ | - |  | $+2 x$ |

As in an arithmetic calculation, in each column, we add the initial value to the change to obtain the "sum," the equilibrium value. Note that we include data only for those substances whose concentrations change; thus, in this case, the column for C (graphite) is blank. Reaction tables appear in many of the equilibrium problems in this and later chapters.

To solve for $K_{\mathrm{p}}$, we must substitute equilibrium values into the reaction quotient, so we first have to find $x$. To do this, we use the other piece of data given, $P_{\text {total }}$. According to Dalton's law of partial pressures and using the quantities from the bottom (equilibrium) row of the reaction table,

$$
P_{\text {total }}=0.757 \mathrm{~atm}=P_{\mathrm{CO}_{2}(\mathrm{eq})}+P_{\mathrm{CO}}=(0.458 \mathrm{~atm}-x)+2 x
$$

Thus, $\quad 0.757 \mathrm{~atm}=0.458 \mathrm{~atm}+x \quad$ and $\quad x=0.299 \mathrm{~atm}$
With $x$ known, we determine the equilibrium partial pressures:

$$
\begin{aligned}
P_{\mathrm{CO}_{2}(\mathrm{eq)}} & =0.458 \mathrm{~atm}-x=0.458 \mathrm{~atm}-0.299 \mathrm{~atm}=0.159 \mathrm{~atm} \\
P_{\mathrm{CO}(\mathrm{eq})} & =2 x=2(0.299 \mathrm{~atm})=0.598 \mathrm{~atm}
\end{aligned}
$$

Now, we substitute these values into the expression for $Q_{\mathrm{p}}$ to find $K_{\mathrm{p}}$ :

$$
Q_{\mathrm{p}}=\frac{P_{\mathrm{CO}(\mathrm{eq})}^{2}}{P_{\mathrm{CO}_{2}(\mathrm{eq})}^{2}}=\frac{0.598^{2}}{0.159}=2.25=K_{\mathrm{p}}
$$

As we predicted, $K_{\mathrm{p}}$ is neither very large nor very small.
(From now on, the subscripts "init" and "eq" appear only when it is not clear whether a concentration or pressure is an initial or equilibrium value.)

## SAMPLE PROBLEM 17.7 Calculating $K_{\mathrm{c}}$ from Concentration Data

PROBLEM In order to study hydrogen halide decomposition, a researcher fills an evacuated 2.00-L flask with 0.200 mol of HI gas and allows the reaction to proceed at $453^{\circ} \mathrm{C}$ :

$$
2 \mathrm{HI}(g) \rightleftharpoons \mathrm{H}_{2}(g)+\mathrm{I}_{2}(g)
$$

At equilibrium, $[\mathrm{HI}]=0.078 \mathrm{M}$. Calculate $K_{\mathrm{c}}$.
PLAN To calculate $K_{\mathrm{c}}$, we need the equilibrium concentrations. We can find the initial [HI] from the amount $(0.200 \mathrm{~mol})$ and the flask volume $(2.00 \mathrm{~L})$, and we are given $[\mathrm{HI}]$ at equilibrium $(0.078 \mathrm{M})$. From the balanced equation, when $2 x \mathrm{~mol}$ of HI reacts, $x \mathrm{~mol}$ of $\mathrm{H}_{2}$ and $x \mathrm{~mol}$ of $\mathrm{I}_{2}$ form. We set up a reaction table, use the known [HI] at equilibrium to solve for $x$ (the change in $\left[\mathrm{H}_{2}\right]$ or $\left[\mathrm{I}_{2}\right]$ ), and substitute the concentrations into $Q_{\mathrm{c}}$.
SOLUTION Calculating initial $[\mathrm{HI}]$ :

$$
[\mathrm{HI}]=\frac{0.200 \mathrm{~mol}}{2.00 \mathrm{~L}}=0.100 \mathrm{M}
$$

Setting up the reaction table, with $x=\left[\mathrm{H}_{2}\right]$ or $\left[\mathrm{I}_{2}\right]$ that forms and $2 x=[\mathrm{HI}]$ that reacts:

| Concentration $(\mathbf{M})$ | $\mathbf{2 H I}(\boldsymbol{g})$ | $\rightleftharpoons$ | $\mathbf{H}_{\mathbf{2}}(\boldsymbol{g})$ | $\mathbf{+}$ |
| :--- | :---: | :---: | :---: | :---: |
| Initial | 0.100 |  | 0 |  |
| Change | $-2 x$ |  | $+x$ | 0 |
| Equilibrium | $0.100-2 x$ |  | $x$ | $+x$ |

Solving for $x$, using the known [HI] at equilibrium:

$$
\begin{aligned}
{[\mathrm{HI}] } & =0.100 M-2 x=0.078 M \\
x & =0.011 M
\end{aligned}
$$

Therefore, the equilibrium concentrations are

$$
\left[\mathrm{H}_{2}\right]=\left[\mathrm{I}_{2}\right]=0.011 \mathrm{M} \quad \text { and } \quad[\mathrm{HI}]=0.078 \mathrm{M}
$$

Substituting into the reaction quotient:

Thus,

$$
\begin{gathered}
Q_{\mathrm{c}}=\frac{\left[\mathrm{H}_{2}\right]\left[\mathrm{I}_{2}\right]}{[\mathrm{HI}]^{2}} \\
K_{\mathrm{c}}=\frac{(0.011)(0.011)}{0.078^{2}}=0.020
\end{gathered}
$$

CHECK Rounding gives $\sim 0.01^{2} / 0.08^{2}=0.02$. Because the initial [HI] of 0.100 M fell slightly at equilibrium to 0.078 M , relatively little product formed; so we expect $K_{\mathrm{c}}<1$.
FOLLOW-UP PROBLEM 17.7 The atmospheric oxidation of nitrogen monoxide, $2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}_{2}(g)$, was studied at $184^{\circ} \mathrm{C}$ with initial pressures of 1.000 atm of NO and 1.000 atm of $\mathrm{O}_{2}$. At equilibrium, $P_{\mathrm{O}_{2}}=0.506 \mathrm{~atm}$. Calculate $K_{\mathrm{p}}$.

## Using the Equilibrium Constant to Determine Quantities

Like the type of problem that involves finding $K$, the type that involves finding equilibrium concentrations (or pressures) has several variations. Sample Problem 17.8 is one variation, in which we know $K$ and some of the equilibrium concentrations and must find another equilibrium concentration.

## SAMPLE PROBLEM 17.8 Determining Equilibrium Concentrations from $K_{\mathrm{c}}$

PROBLEM In a study of the conversion of methane to other fuels, a chemical engineer mixes gaseous $\mathrm{CH}_{4}$ and $\mathrm{H}_{2} \mathrm{O}$ in a 0.32 -L flask at 1200 K . At equilibrium, the flask contains 0.26 mol of $\mathrm{CO}, 0.091 \mathrm{~mol}$ of $\mathrm{H}_{2}$, and 0.041 mol of $\mathrm{CH}_{4}$. What is $\left[\mathrm{H}_{2} \mathrm{O}\right]$ at equilibrium? $K_{\mathrm{c}}=0.26$ for the equation

$$
\mathrm{CH}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons \mathrm{CO}(g)+3 \mathrm{H}_{2}(g)
$$

PLAN First, we use the balanced equation to write the reaction quotient. We can calculate the equilibrium concentrations from the given numbers of moles and the flask volume $(0.32 \mathrm{~L})$. Substituting these into $Q_{\mathrm{c}}$ and setting it equal to the given $K_{\mathrm{c}}(0.26)$, we solve for the unknown equilibrium concentration, $\left[\mathrm{H}_{2} \mathrm{O}\right]$.

SOLUTION Writing the reaction quotient:

$$
\mathrm{CH}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons \mathrm{CO}(g)+3 \mathrm{H}_{2}(g) \quad Q_{\mathrm{c}}=\frac{[\mathrm{CO}]\left[\mathrm{H}_{2}\right]^{3}}{\left[\mathrm{CH}_{4}\right]\left[\mathrm{H}_{2} \mathrm{O}\right]}
$$

Determining the equilibrium concentrations:

$$
\left[\mathrm{CH}_{4}\right]=\frac{0.041 \mathrm{~mol}}{0.32 \mathrm{~L}}=0.13 \mathrm{M}
$$

Similarly, $[\mathrm{CO}]=0.81 \mathrm{M}$ and $\left[\mathrm{H}_{2}\right]=0.28 \mathrm{M}$.
Calculating $\left[\mathrm{H}_{2} \mathrm{O}\right]$ at equilibrium: Since $Q_{\mathrm{c}}=K_{\mathrm{c}}$, rearranging gives

$$
\left[\mathrm{H}_{2} \mathrm{O}\right]=\frac{[\mathrm{CO}]\left[\mathrm{H}_{2}\right]^{3}}{\left[\mathrm{CH}_{4}\right] K_{\mathrm{c}}}=\frac{(0.81)(0.28)^{3}}{(0.13)(0.26)}=0.53 \mathrm{M}
$$

CHECK Always check by substituting the concentrations into $Q_{\mathrm{c}}$ to confirm $K_{\mathrm{c}}$ :

$$
Q_{\mathrm{c}}=\frac{[\mathrm{CO}]\left[\mathrm{H}_{2}\right]^{3}}{\left[\mathrm{CH}_{4}\right]\left[\mathrm{H}_{2} \mathrm{O}\right]}=\frac{(0.81)(0.28)^{3}}{(0.13)(0.53)}=0.26=K_{\mathrm{c}}
$$

FOLLOW-UP PROBLEM 17.8 Nitrogen monoxide decomposes by the following equation: $2 \mathrm{NO}(g) \rightleftharpoons \mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) ; K_{\mathrm{c}}=2.3 \times 10^{30}$ at 298 K . In the atmosphere, $P_{\mathrm{O}_{2}}=0.209 \mathrm{~atm}$ and $P_{\mathrm{N}_{2}}=0.781 \mathrm{~atm}$. What is the equilibrium partial pressure of NO in the air we breathe? [Hint: You need $K_{\mathrm{p}}$ to find the partial pressure.]

In a somewhat more involved variation, we know $K$ and initial quantities and must find equilibrium quantities, for which we use a reaction table. In Sample Problem 17.9, the amounts were chosen to simplify the math, allowing us to focus more easily on the overall approach.

## SAMPLE PROBLEM 17.9 Determining Equilibrium Concentrations from Initial Concentrations and $K_{c}$

PROBLEM Fuel engineers use the extent of the change from CO and $\mathrm{H}_{2} \mathrm{O}$ to $\mathrm{CO}_{2}$ and $\mathrm{H}_{2}$ to regulate the proportions of synthetic fuel mixtures. If 0.250 mol of CO and 0.250 mol of $\mathrm{H}_{2} \mathrm{O}$ are placed in a $125-\mathrm{mL}$ flask at 900 K , what is the composition of the equilibrium mixture? At this temperature, $K_{\mathrm{c}}$ is 1.56 for the equation

$$
\mathrm{CO}(g)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons \mathrm{CO}_{2}(g)+\mathrm{H}_{2}(g)
$$

PLAN We have to find the "composition" of the equilibrium mixture, in other words, the equilibrium concentrations. As always, we use the balanced equation to write the reaction quotient. We find the initial $[\mathrm{CO}]$ and $\left[\mathrm{H}_{2} \mathrm{O}\right]$ from the given amounts $(0.250 \mathrm{~mol}$ of each $)$ and volume $(0.125 \mathrm{~L})$, use the balanced equation to define $x$ and set up a reaction table, substitute into $Q_{\mathrm{c}}$, and solve for $x$, from which we calculate the concentrations.
SOLUTION Writing the reaction quotient:

$$
\mathrm{CO}(g)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons \mathrm{CO}_{2}(g)+\mathrm{H}_{2}(g) \quad Q_{\mathrm{c}}=\frac{\left[\mathrm{CO}_{2}\right]\left[\mathrm{H}_{2}\right]}{[\mathrm{CO}]\left[\mathrm{H}_{2} \mathrm{O}\right]}
$$

Calculating initial reactant concentrations:

$$
[\mathrm{CO}]=\left[\mathrm{H}_{2} \mathrm{O}\right]=\frac{0.250 \mathrm{~mol}}{0.125 \mathrm{~L}}=2.00 \mathrm{M}
$$

Setting up the reaction table, with $x=[\mathrm{CO}]$ and $\left[\mathrm{H}_{2} \mathrm{O}\right]$ that react:

| Concentration $(\mathbf{M})$ | $\mathbf{C O}(g)$ | + | $\mathbf{H}_{\mathbf{2}} \mathbf{O}(g)$ | $\rightleftharpoons$ | $\mathbf{C O}_{\mathbf{2}}(g)$ | + |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{H}_{\mathbf{2}}(g)$ |  |  |  |  |  |  |
| Initial | 2.00 | 2.00 |  | 0 | 0 |  |
| Change | $-x$ | $-x$ |  | $+x$ | $+x$ |  |
| Equilibrium | $2.00-x$ | $2.00-x$ |  | $x$ | $x$ |  |

Substituting into the reaction quotient and solving for $x$ :

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{CO}_{2}\right]\left[\mathrm{H}_{2}\right]}{[\mathrm{CO}]\left[\mathrm{H}_{2} \mathrm{O}\right]}=\frac{(x)(x)}{(2.00-x)(2.00-x)}=\frac{x^{2}}{(2.00-x)^{2}}
$$

At equilibrium, we have

$$
Q_{\mathrm{c}}=K_{\mathrm{c}}=1.56=\frac{x^{2}}{(2.00-x)^{2}}
$$

We can apply the following math shortcut in this case but not in general: Because the right side of the equation is a perfect square, we take the square root of both sides:

$$
\sqrt{1.56}=\frac{x}{2.00-x}= \pm 1.25
$$

A positive number (1.56) has a positive and a negative square root, but only the positive root has any chemical meaning, so we ignore the negative root:*

$$
1.25=\frac{x}{2.00-x} \quad \text { or } \quad 2.50-1.25 x=x
$$

So $\quad 2.50=2.25 x ; \quad$ therefore,$\quad x=1.11 M$
Calculating equilibrium concentrations:

$$
\begin{aligned}
{[\mathrm{CO}] } & =\left[\mathrm{H}_{2} \mathrm{O}\right]=2.00 \mathrm{M}-x=2.00 \mathrm{M}-1.11 \mathrm{M}=0.89 \mathrm{M} \\
{\left[\mathrm{CO}_{2}\right] } & =\left[\mathrm{H}_{2}\right]=x=1.11 \mathrm{M}
\end{aligned}
$$

CHECK From the intermediate size of $K_{\mathrm{c}}$, it makes sense that the changes in concentration are moderate. It's a good idea to check that the sign of $x$ in the reaction table makes sense-only reactants were initially present, so the change had to proceed to the right: $x$ is the change in concentration, so it has a negative sign for reactants and a positive sign for products. Also check that the equilibrium concentrations give the known $K_{\mathrm{c}}$ : $\frac{(1.11)(1.11)}{(0.89)(0.89)}=1.56$.

FOLLOW-UP PROBLEM 17.9 The decomposition of HI at low temperature was studied by injecting 2.50 mol of HI into a $10.32-\mathrm{L}$ vessel at $25^{\circ} \mathrm{C}$. What is $\left[\mathrm{H}_{2}\right]$ at equilibrium for the reaction $2 \mathrm{HI}(g) \rightleftharpoons \mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) ; K_{\mathrm{c}}=1.26 \times 10^{-3}$ ?

Using the Quadratic Formula to Solve for the Unknown The shortcut that we used to simplify the math in Sample Problem 17.9 is a special case that occurs when both numerator and denominator of the reaction quotient are perfect squares. It worked out that way because we started with equal concentrations of the two reactants, but that is not ordinarily the case.

Suppose, for example, we instead start the reaction in the sample problem with 2.00 MCO and $1.00 \mathrm{M}_{2} \mathrm{O}$. Now, the reaction table becomes

| Concentration $(\mathbf{M})$ | $\mathbf{C O}(\mathbf{g})$ | $\mathbf{+}$ | $\mathbf{H}_{\mathbf{2}} \mathbf{O}(\mathbf{g})$ | $\rightleftharpoons$ | $\mathbf{C O}_{\mathbf{2}}(\boldsymbol{g})$ | $\mathbf{+}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| H2 $\mathbf{( g )}$ |  |  |  |  |  |  |
| Initial | 2.00 |  | 1.00 |  | 0 | 0 |
| Change | $-x$ | $-x$ | $1.00-x$ |  | $x$ | $+x$ |
| Equilibrium | $2.00-x$ |  |  | $x$ | $x$ |  |

Substituting these values into $Q_{\mathrm{c}}$, we obtain

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{CO}_{2}\right]\left[\mathrm{H}_{2}\right]}{[\mathrm{CO}]\left[\mathrm{H}_{2} \mathrm{O}\right]}=\frac{(x)(x)}{(2.00-x)(1.00-x)}=\frac{x^{2}}{x^{2}-3.00 x+2.00}
$$

At equilibrium, we have

$$
1.56=\frac{x^{2}}{x^{2}-3.00 x+2.00}
$$

*The negative root gives $-1.25=\frac{x}{2.00-x}$, or $-2.50+1.25 x=x$.
So $\quad-2.50=-0.25 x$, and $x=10 . M$
This value has no chemical meaning because we started with 2.00 M of each reactant, so it is impossible for 10. $M$ to react. Moreover, the square root of an equilibrium constant is another equilibrium constant, which cannot have a negative value.

To solve for $x$ in this case, we rearrange the previous expression into the form of a quadratic equation:

$$
\begin{array}{r}
a x^{2}+b x+c=0 \\
0.56 x^{2}-4.68 x+3.12=0
\end{array}
$$

where $a=0.56, b=-4.68$, and $c=3.12$. Then we find $x$ with the quadratic formula (Appendix A):

$$
x=\frac{-b \pm \sqrt{b^{2}-4 a c}}{2 a}
$$

The $\pm$ sign means that we obtain two possible values for $x$ :

$$
\begin{aligned}
& x=\frac{4.68 \pm \sqrt{(-4.68)^{2}-4(0.56)(3.12)}}{2(0.56)} \\
& x=7.6 M \quad \text { and } \quad x=0.73 M
\end{aligned}
$$

Note that only one of the values for $x$ makes sense chemically. The larger value gives negative concentrations at equilibrium (for example, $2.00 M-7.6 M=$ $-5.6 M$ ), which have no meaning. Therefore, $x=0.73 M$, and we have

$$
\begin{aligned}
{[\mathrm{CO}] } & =2.00 \mathrm{M}-x=2.00 \mathrm{M}-0.73 \mathrm{M}=1.27 \mathrm{M} \\
{\left[\mathrm{H}_{2} \mathrm{O}\right] } & =1.00 \mathrm{M}-x=0.27 \mathrm{M} \\
{\left[\mathrm{CO}_{2}\right] } & =\left[\mathrm{H}_{2}\right]=x=0.73 \mathrm{M}
\end{aligned}
$$

Checking to see if these values give the known $K_{\mathrm{c}}$, we have

$$
K_{\mathrm{c}}=\frac{(0.73)(0.73)}{(1.27)(0.27)}=1.6(\text { within rounding of } 1.56)
$$

Simplifying Assumption for Finding an Unknown Quantity In many cases, we can use chemical "common sense" to make an assumption that avoids the use of
 and a relatively large initial reactant concentration, the concentration change ( $x$ ) can often be neglected without introducing significant error. This assumption does not mean that $x=0$, because then there would be no reaction at all. It means that if a reaction proceeds very little (small $K$ ) and and starts out with a high initial reactant concentration, only a very small proportion will be used up; therefore, at equilibrium, the reactant concentration will have hardly changed:

$$
[\text { reactant }]_{\text {init }}-x=[\text { reactant }]_{\mathrm{eq}} \approx[\text { reactant }]_{\mathrm{init}}
$$

Here's a similar situation from everyday life. On a bathroom scale, you weigh 158 lb . Take off your wristwatch, and you still weigh 158 lb . Within the precision of the measurement, the weight of the wristwatch is so small compared with your body weight that it can be neglected:

Initial body weight - weight of watch $=$ final body weight $\approx$ initial body weight
Similarly, if the initial concentration of A is, for example, 0.500 M and, because of a small $K_{\mathrm{c}}$, the concentration of A that reacts is 0.002 M , we can assume that

$$
0.500 M-0.002 M=0.498 M \approx 0.500 M
$$

that is,

$$
\begin{equation*}
[\mathrm{A}]_{\text {init }}-[\mathrm{A}]_{\text {reacting }}=[\mathrm{A}]_{\text {eq }} \approx[\mathrm{A}]_{\text {init }} \tag{17.9}
\end{equation*}
$$

To justify the assumption that $x$, the concentration reacting, is negligible, you must check that the error introduced is not significant. One common criterion for "significant" is the $5 \%$ rule: if the assumption results in a change that is less than $5 \%$ of the initial concentration, the error is not significant, and the assumption is justified. Let's make this assumption in a sample problem to see how it simplifies the math and if it is justified in the cases of two different initial concentrations. (We make this assumption often in Chapters 18 and 19.)

## SAMPLE PROBLEM 17.10 Calculating Equilibrium Concentrations with a Simplifying Assumption

PROBLEM Phosgene is a potent chemical warfare agent that is now outlawed by international agreement. It decomposes by the reaction

$$
\mathrm{COCl}_{2}(g) \rightleftharpoons \mathrm{CO}(g)+\mathrm{Cl}_{2}(g) \quad K_{\mathrm{c}}=8.3 \times 10^{-4}\left(\text { at } 360^{\circ} \mathrm{C}\right)
$$

Calculate $[\mathrm{CO}],\left[\mathrm{Cl}_{2}\right]$, and $\left[\mathrm{COCl}_{2}\right]$ when each of the following amounts of phosgene decomposes and reaches equilibrium in a 10.0-L flask:
(a) 5.00 mol of $\mathrm{COCl}_{2}$
(b) 0.100 mol of $\mathrm{COCl}_{2}$

PLAN We know from the balanced equation that when $x \mathrm{~mol}$ of $\mathrm{COCl}_{2}$ decomposes, $x \mathrm{~mol}$ of CO and $x \mathrm{~mol}$ of $\mathrm{Cl}_{2}$ form. We use the volume $(10.0 \mathrm{~L})$ to convert amount $(5.00 \mathrm{~mol}$ or 0.100 mol ) to concentration, define $x$ and set up the reaction table, and substitute the values into $Q_{\mathrm{c}}$. Before using the quadratic formula, we assume that $x$ is negligibly small. After solving for $x$, we check the assumption and find the concentrations. If the assumption is not justified, we must use the quadratic formula to find $x$.
SOLUTION (a) For 5.00 mol of $\mathrm{COCl}_{2}$. Writing the reaction quotient:

$$
Q_{\mathrm{c}}=\frac{[\mathrm{CO}]\left[\mathrm{Cl}_{2}\right]}{\left[\mathrm{COCl}_{2}\right]}
$$

Calculating initial $\left[\mathrm{COCl}_{2}\right]$ :

$$
\left[\mathrm{COCl}_{2}\right]_{\text {init }}=\frac{5.00 \mathrm{~mol}}{10.0 \mathrm{~L}}=0.500 \mathrm{M}
$$

Setting up the reaction table, with $x$ in the "Change" row equal to $\left[\mathrm{COCl}_{2}\right]_{\text {reacting }}$ :

| Concentration $(\mathbf{M})$ | $\mathbf{C O C l}_{\mathbf{2}}(\boldsymbol{g})$ | $\rightleftharpoons$ | $\mathbf{C O}(\boldsymbol{g})$ | + |
| :--- | :---: | :---: | :---: | :---: |
| $\mathrm{Cl}_{\mathbf{2}}(\boldsymbol{g})$ |  |  |  |  |
| Initial | 0.500 |  | 0 | 0 |
| Change | $-x$ |  | $+x$ | $+x$ |
| Equilibrium | $0.500-x$ |  | $x$ | $x$ |

If we use the equilibrium values in $Q_{\mathrm{c}}$, we obtain

$$
Q_{\mathrm{c}}=\frac{[\mathrm{CO}]\left[\mathrm{Cl}_{2}\right]}{\left[\mathrm{COCl}_{2}\right]}=\frac{x^{2}}{0.500-x}=K_{\mathrm{c}}=8.3 \times 10^{-4}
$$

Because $K_{\mathrm{c}}$ is small, the reaction does not proceed very far to the right, so let's simplify the math by assuming that $x\left(\left[\mathrm{COCl}_{2}\right]_{\text {reacting }}\right)$ is so small that the equilibrium concentration is nearly the same as the initial concentration, 0.500 M . Therefore,

$$
0.500 M-x \approx 0.500 M
$$

Using this assumption, we substitute and solve for $x$ :

$$
\begin{gathered}
K_{\mathrm{c}}=8.3 \times 10^{-4} \approx \frac{x^{2}}{0.500} \\
x^{2} \approx\left(8.3 \times 10^{-4}\right)(0.500) \quad \text { so } \quad x \approx 2.0 \times 10^{-2}
\end{gathered}
$$

Checking the assumption by finding the percent error:

$$
\frac{[\text { Change }]}{[\text { Initial }]}=\frac{2.0 \times 10^{-2}}{0.500} \times 100=4 \%(\text { less than } 5 \%, \text { so the assumption is justified })
$$

Solving for the equilibrium concentrations:

$$
\begin{aligned}
{[\mathrm{CO}] } & =\left[\mathrm{Cl}_{2}\right]=x=2.0 \times 10^{-2} \mathrm{M} \\
{\left[\mathrm{COCl}_{2}\right] } & =0.500 \mathrm{M}-x=0.480 \mathrm{M}
\end{aligned}
$$

(b) For 0.100 mol of $\mathrm{COCl}_{2}$. The calculation in this case is the same as the calculation in part (a), except that $\left[\mathrm{COCl}_{2}\right]_{\text {init }}=0.100 \mathrm{~mol} / 10.0 \mathrm{~L}=0.0100 \mathrm{M}$. Thus, at equilibrium,

$$
\begin{aligned}
Q_{\mathrm{c}} & =\frac{[\mathrm{CO}]\left[\mathrm{Cl}_{2}\right]}{\left[\mathrm{COCl}_{2}\right]}=\frac{x^{2}}{0.0100-x} \\
& =K_{\mathrm{c}}=8.3 \times 10^{-4}
\end{aligned}
$$

Making the assumption that $0.0100 M-x \approx 0.0100 M$ and solving for $x$ :

$$
K_{\mathrm{c}}=8.3 \times 10^{-4} \approx \frac{x^{2}}{0.0100} \quad x \approx 2.9 \times 10^{-3}
$$

Checking the assumption:

$$
\frac{2.9 \times 10^{-3}}{0.0100} \times 100=29 \% \quad(\text { more than } 5 \%, \text { so the assumption is not justified })
$$

We must solve the quadratic equation, $x^{2}+\left(8.3 \times 10^{-4}\right) x-\left(8.3 \times 10^{-6}\right)=0$, for which the only meaningful value of $x$ is $2.5 \times 10^{-3}$ (see Appendix A).
Solving for the equilibrium concentrations:

$$
\begin{aligned}
{[\mathrm{CO}] } & =\left[\mathrm{Cl}_{2}\right]=2.5 \times 10^{-3} M \\
{\left[\mathrm{COCl}_{2}\right] } & =1.00 \times 10^{-2} M-x=7.5 \times 10^{-3} M
\end{aligned}
$$

CHECK Once again, the best check is to use the calculated values to be sure you obtain the given $K_{\text {c }}$.
COMMENT Note that the simplifying assumption was justified at the high $\left[\mathrm{COCl}_{2}\right]_{\text {init }}$ but not at the low $\left[\mathrm{COCl}_{2}\right]_{\text {init. }}$. To summarize, we assume that $x\left([\mathrm{~A}]_{\text {reacting }}\right)$ can be neglected if $K_{\mathrm{c}}$ is small relative to $[\mathrm{A}]_{\text {init }}$. The same holds for $K_{\mathrm{p}}$ and $P_{\mathrm{A} \text { (init) }}$. Here's a benchmark for determining when the assumption is justified:

- If $\frac{[\mathrm{A}]_{\text {init }}}{K_{\mathrm{c}}}>400$, the assumption is justified: neglecting $x$ introduces an error $<5 \%$.
- If $\frac{[\mathrm{A}]_{\text {init }}}{K_{\mathrm{c}}}<400$, the assumption is not justified; neglecting $x$ introduces an error $>5 \%$, so we solve a quadratic equation to find $x$.
FOLLOW-UP PROBLEM 17.10 In a study of the effect of temperature on halogen decomposition, 0.50 mol of $\mathrm{I}_{2}$ was heated in a $2.5-\mathrm{L}$ vessel, and the following reaction occurred: $\mathrm{I}_{2}(g) \rightleftharpoons 2 \mathrm{I}(\mathrm{g})$.
(a) Calculate $\left[\mathrm{I}_{2}\right]$ and $[\mathrm{I}]$ at equilibrium at $600 \mathrm{~K} ; K_{\mathrm{c}}=2.94 \times 10^{-10}$.
(b) Calculate $\left[\mathrm{I}_{2}\right]$ and $[\mathrm{I}]$ at equilibrium at $2000 \mathrm{~K} ; K_{\mathrm{c}}=0.209$.

## Mixtures of Reactants and Productso PDF Enhancer Determining Reaction Direction

In the problems we've worked so far, the direction of the reaction was obvious: with only reactants present at the start, the reaction had to go toward products. Thus, in the reaction tables, we knew that the unknown change in reactant concentration had a negative sign $(-x)$ and the change in product concentration had a positive sign $(+x)$. Suppose, however, we start with a mixture of reactants and products. Whenever the reaction direction is not obvious, we first compare the value of $Q$ with $K$ to find the direction in which the reaction proceeds to reach equilibrium. This tells us the sign of $x$, the unknown change in concentration. (In order to focus on this idea, the next sample problem eliminates the need for the quadratic formula.)

## SAMPLE PROBLEM 17.11 Predicting Reaction Direction and

 Calculating Equilibrium ConcentrationsPROBLEM The research and development unit of a chemical company is studying the reaction of $\mathrm{CH}_{4}$ and $\mathrm{H}_{2} \mathrm{~S}$, two components of natural gas:

$$
\mathrm{CH}_{4}(g)+2 \mathrm{H}_{2} \mathrm{~S}(g) \rightleftharpoons \mathrm{CS}_{2}(g)+4 \mathrm{H}_{2}(g)
$$

In one experiment, 1.00 mol of $\mathrm{CH}_{4}, 1.00 \mathrm{~mol}$ of $\mathrm{CS}_{2}, 2.00 \mathrm{~mol}$ of $\mathrm{H}_{2} \mathrm{~S}$, and 2.00 mol of $\mathrm{H}_{2}$ are mixed in a $250-\mathrm{mL}$ vessel at $960^{\circ} \mathrm{C}$. At this temperature, $K_{\mathrm{c}}=0.036$.
(a) In which direction will the reaction proceed to reach equilibrium?
(b) If $\left[\mathrm{CH}_{4}\right]=5.56 \mathrm{M}$ at equilibrium, what are the equilibrium concentrations of the other substances?
PLAN (a) To find the direction, we convert the given initial amounts and volume ( 0.250 L ) to concentrations, calculate $Q_{\mathrm{c}}$, and compare it with $K_{\mathrm{c}}$. (b) Based on the results from (a), we determine the sign of each concentration change for the reaction table and then use the known $\left[\mathrm{CH}_{4}\right]$ at equilibrium $(5.56 M)$ to determine $x$ and the other equilibrium concentrations.

## SOLVING EQUILIBRIUM PROBLEMS

PRELIMINARY SETTING UP

1. Write the balanced equation
2. Write the reaction quotient, $Q$
3. Convert all amounts into the correct units ( $M$ or atm)

## WORKING ON THE REACTION TABLE

4. When reaction direction is not known, compare $Q$ with $K$
5. Construct a reaction table
$\checkmark$ Check the sign of $x$, the change in the concentration (or pressure)

## SOLVING FOR x AND EQUILIBRIUM QUANTITIES

6. Substitute the quantities into $Q$
7. To simplify the math, assume that $x$ is negligible
$\left([\mathrm{A}]_{\text {init }}-x=[\mathrm{A}]_{\text {eq }} \approx[\mathrm{A}]_{\text {init }}\right)$
8. Solve for $x$
$\sqrt{ }$ Check that assumption is justified (<5\% error). If not, solve quadratic equation for $x$.
9. Find the equilibrium quantities

Check to see that calculated values give the known $K$

Figure 17.6 Steps in solving equilibrium problems. These nine steps, grouped into three tasks, provide a useful approach to calculating equilibrium quantities, given initial quantities and $K$.

SOLUTION (a) Calculating the initial concentrations:

$$
\left[\mathrm{CH}_{4}\right]=\frac{1.00 \mathrm{~mol}}{0.250 \mathrm{~L}}=4.00 \mathrm{M}
$$

Similarly, $\left[\mathrm{H}_{2} \mathrm{~S}\right]=8.00 \mathrm{M},\left[\mathrm{CS}_{2}\right]=4.00 \mathrm{M}$, and $\left[\mathrm{H}_{2}\right]=8.00 \mathrm{M}$.
Calculating the value of $Q_{\mathrm{c}}$ :

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{CS}_{2}\right]\left[\mathrm{H}_{2}\right]^{4}}{\left[\mathrm{CH}_{4}\right]\left[\mathrm{H}_{2} \mathrm{~S}\right]^{2}}=\frac{(4.00)(8.00)^{4}}{(4.00)(8.00)^{2}}=64.0
$$

Comparing $Q_{\mathrm{c}}$ and $K_{\mathrm{c}}: Q_{\mathrm{c}}>K_{\mathrm{c}}(64.0>0.036)$, so the reaction goes to the left. Therefore, concentrations of reactants increase and those of products decrease.
(b) Setting up a reaction table, with $x=\left[\mathrm{CS}_{2}\right]$ that reacts, which equals $\left[\mathrm{CH}_{4}\right]$ that forms:

| Concentration $(\mathbf{M})$ | $\mathbf{C H}_{\mathbf{4}}(\mathbf{g})$ | $\mathbf{+}$ | $\mathbf{2 H}_{\mathbf{2}} \mathbf{S}(\mathbf{g})$ | $\rightleftharpoons$ | $\mathbf{C S}_{\mathbf{2}}(\boldsymbol{g})$ | $\mathbf{+}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Initial | 4.00 | 8.00 |  | 4.00 | 8.00 |  |
| Change | $+x$ | $+2 x$ |  | $-x$ | $-4 x$ |  |
| Equilibrium | $4.00+x$ | $8.00+2 x$ |  | $4.00-x$ | $8.00-4 x$ |  |

Solving for $x$ : At equilibrium,

$$
\begin{gathered}
{\left[\mathrm{CH}_{4}\right]=5.56 M=4.00 M+x} \\
x=1.56 \mathrm{M}
\end{gathered}
$$

So,
Thus,

$$
\begin{aligned}
{\left[\mathrm{H}_{2} \mathrm{~S}\right] } & =8.00 M+2 x=8.00 M+2(1.56 M)=11.12 M \\
{\left[\mathrm{CS}_{2}\right] } & =4.00 M-x=2.44 M \\
{\left[\mathrm{H}_{2}\right] } & =8.00 M-4 x=1.76 \mathrm{M}
\end{aligned}
$$

CHECK The comparison of $Q_{\mathrm{c}}$ and $K_{\mathrm{c}}$ showed the reaction proceeding to the left. The given data from part (b) confirm this because $\left[\mathrm{CH}_{4}\right]$ increases from 4.00 M to 5.56 M during the reaction. Check that the concentrations give the known $K_{\mathrm{c}}$ :

$$
\frac{(2.44)(1.76)^{4}}{(5.56)(11.12)^{2}}=0.0341, \text { which is close to } 0.036
$$

FOLLOW-UP PROBLEM 17.11 An inorganic chemist studying the reactions of phosphorus halides mixes 0.1050 mol of $\mathrm{PCl}_{5}$ with 0.0450 mol of $\mathrm{Cl}_{2}$ and 0.0450 mol of $\mathrm{PCl}_{3}$ in a 0.5000 -L flask at $250^{\circ} \mathrm{C}: \mathrm{PCl}_{5}(\mathrm{~g}) \rightleftharpoons \mathrm{PCl}_{3}(\mathrm{~g})+\mathrm{Cl}_{2}(\mathrm{~g}) ; K_{\mathrm{c}}=4.2 \times 10^{-2}$.
(a) In which direction will the reaction proceed?
(b) If $\left[\mathrm{PCl}_{5}\right]=0.2065 M$ at equilibrium, what are the equilibrium concentrations of the other components?

By this time, you've seen quite a few variations on the type of equilibrium problem in which you know $K$ and some initial quantities and must find the equilibrium quantities. Figure 17.6 presents a useful summary of the steps involved in solving these types of equilibrium problems. A good way to organize the steps is to group them into three overall parts, as the figure shows.

## Section Summary

In equilibrium problems, we typically use quantities (concentrations or pressures) of reactants and products to find $K$, or we use $K$ to find quantities. - Reaction tables summarize the initial quantities, how they change, and the equilibrium quantities. To simplify calculations, we assume that if $K$ is small and the initial quantity of reactant is large, the unknown change in reactant $(x)$ can be neglected. If this assumption is not justified (that is, if the error is greater than 5\%), we use the quadratic formula to find $x$. - To determine reaction direction, we compare the values of $Q$ and $K$.

### 17.6 REACTION CONDITIONS AND THE EQUILIBRIUM STATE: LE CHÂTELIER'S PRINCIPLE

The most remarkable feature of a system at equilibrium is its ability to return to equilibrium after a change in conditions moves it away from that state. This drive to reattain equilibrium is stated in Le Châtelier's principle: when a chemical system at equilibrium is disturbed, it reattains equilibrium by undergoing a net reaction that reduces the effect of the disturbance.

Two phrases in this statement need further explanation. First, what does it mean to "disturb" a system? At equilibrium, $Q$ equals $K$. When a change in conditions forces the system temporarily out of equilibrium $(Q \neq K)$, we say that the system has been stressed, or disturbed. Three common disturbances are a change in concentration of a component (that appears in $Q$ ), a change in pressure (caused by a change in volume), or a change in temperature. We'll discuss each of these changes below.

The other phrase, "net reaction," is often referred to as a shift in the equilibrium position of the system to the right or left. The equilibrium position is just the specific equilibrium concentrations (or pressures). A shift in the equilibrium position to the right means that there is a net reaction to the right (reactant to product) until equilibrium is reattained; a shift to the left means that there is a net reaction to the left (product to reactant). Thus, when a disturbance occurs, we say that the equilibrium position shifts, which means that concentrations (or pressures) change in a way that reduces the disturbance, and the system attains a new equilibrium position ( $Q=K$ again).

Le Châtelier's principle allows us to predict the direction of the shift in equilibrium position. Most importantly, it helps research and industrial chemists create conditions that maximize yields. Fir thefenaindenofthissectionawe examine each of the three kinds of disturbances-concentration, pressure (volume), and temperature-to see how a system at equilibrium responds; then, we'll note whether a catalyst has any effect.

In the following discussions, we focus on the reversible gaseous reaction between phosphorus trichloride and chlorine to produce phosphorus pentachloride:

$$
\mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g) \rightleftharpoons \mathrm{PCl}_{5}(g)
$$

However, the basis of Le Châtelier's principle holds for any system at equilibrium, whether in the natural or social sciences.

## The Effect of a Change in Concentration

When a system at equilibrium is disturbed by a change in concentration of one of the components, the system reacts in the direction that reduces the change:

- If the concentration increases, the system reacts to consume some of it.
- If the concentration decreases, the system reacts to produce some of it.

Of course, the component must be one that appears in $Q$; thus, pure liquids and solids, which do not appear in $Q$ because their concentrations are constant, are not involved.

At 523 K , the $\mathrm{PCl}_{3}-\mathrm{Cl}_{2}-\mathrm{PCl}_{5}$ system reaches equilibrium when

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{PCl}_{5}\right]}{\left[\mathrm{PCl}_{3}\right]\left[\mathrm{Cl}_{2}\right]}=24.0=K_{\mathrm{c}}
$$

What happens if we now inject some $\mathrm{Cl}_{2}$ gas, one of the reactants? The system will always act to reduce the disturbance, so it will reduce the increase in reactant

The Universality of Le Châtelier's Principle Although Le Châtelier limited the scope of his principle to physical and chemical systems, its application is much wider. Ecologists and economists, for example, often see it at work. On the African savannah, the numbers of herbivores (antelope, wildebeest, zebra) and carnivores (lion, cheetah) are in delicate balance. Any disturbance (drought, disease) causes shifts in the relative numbers until they attain a new balance. The economic principle of supply-and-demand is another example of this equilibrium principle. A given demand-supply balance for a product establishes a given price. If either demand or supply is disturbed, the disturbance causes a shift in the other and, therefore, in the prevailing price until a new balance is attained.

ANY OF THESE CHANGES CAUSES A SHIFT TO THE RIGHT

ANY OF THESE CHANGES CAUSES A SHIFT TO THE LEFT
Figure 17.7 The effect of a change in concentration.
by proceeding toward the product side, thereby consuming some of the additional $\mathrm{Cl}_{2}$. In terms of the reaction quotient, when we add $\mathrm{Cl}_{2}$, the $\left[\mathrm{Cl}_{2}\right]$ term increases, so the value of $Q_{\mathrm{c}}$ immediately falls as the denominator becomes larger; thus, the system is no longer at equilibrium. As some of the added $\mathrm{Cl}_{2}$ reacts with some of the $\mathrm{PCl}_{3}$ present and produces more $\mathrm{PCl}_{5}$, the denominator becomes smaller once again and the numerator larger, until eventually $Q_{\mathrm{c}}$ again equals $K_{\mathrm{c}}$. The concentrations of the components have changed, however: the concentrations of $\mathrm{Cl}_{2}$ and $\mathrm{PCl}_{5}$ are higher than in the original equilibrium position, and the concentration of $\mathrm{PCl}_{3}$ is lower. Nevertheless, the ratio of values gives the same $K_{\mathrm{c}}$. We describe this change by saying that the equilibrium position shifts to the right when a component on the left is added:

$$
\mathrm{PCl}_{3}+\mathrm{Cl}_{2}(\text { added }) \longrightarrow \mathrm{PCl}_{5}
$$

What happens if, instead of adding $\mathrm{Cl}_{2}$, we remove some $\mathrm{PCl}_{3}$, the other reactant? In this case, the system reduces the disturbance (the decrease in reactant), by proceeding toward the reactant side, thereby consuming some $\mathrm{PCl}_{5}$. Once again, thinking in terms of $Q_{\mathrm{c}}$, when we remove $\mathrm{PCl}_{3}$, the $\left[\mathrm{PCl}_{3}\right]$ term decreases, the denominator becomes smaller, and the value of $Q_{\mathrm{c}}$ rises above $K_{\mathrm{c}}$. As some of the $\mathrm{PCl}_{5}$ decomposes to $\mathrm{PCl}_{3}$ and $\mathrm{Cl}_{2}$, the numerator decreases and the denominator increases until $Q_{\mathrm{c}}$ equals $K_{\mathrm{c}}$ once again. Here, too, the concentrations are different from those of the original equilibrium position, but the value of $K_{\mathrm{c}}$ is not. We say that the equilibrium position shifts to the left when a component on the left is removed:

$$
\mathrm{PCl}_{3}(\text { removed })+\mathrm{Cl}_{2} \longleftarrow \mathrm{PCl}_{5}
$$

The same points we just made for adding or removing a reactant also hold for adding or removing a product. If we add $\mathrm{PCl}_{5}$, its concentration rises and the equilibrium position shifts to the left, just as it did when we removed some $\mathrm{PCl}_{3}$; ifwPrene some $\mathrm{PCl}_{5}$, the dqumbitar Position shifts to the right, just as it did when we added some $\mathrm{Cl}_{2}$. In other words, no matter how the disturbance in concentration comes about, the system responds to make $Q_{\mathrm{c}}$ and $K_{\mathrm{c}}$ equal again. To summarize the effects of concentration changes (Figure 17.7),

- The equilibrium position shifts to the right if a reactant is added or a product is removed: [reactant] increases or [product] decreases.
- The equilibrium position shifts to the left if a reactant is removed or a product is added: [reactant] decreases or [product] increases.

In general, whenever the concentration of a component changes, the equilibrium system reacts to consume some of the added substance or produce some of the removed substance. In this way, the system "reduces the effect of the disturbance." The effect is not completely eliminated, however, as you'll see next from a quantitative comparison of original and new equilibrium positions.

Consider the case in which we added $\mathrm{Cl}_{2}$ to the system at equilibrium. Suppose the original equilibrium position was established with the following concentrations: $\left[\mathrm{PCl}_{3}\right]=0.200 \mathrm{M},\left[\mathrm{Cl}_{2}\right]=0.125 \mathrm{M}$, and $\left[\mathrm{PCl}_{5}\right]=0.600 \mathrm{M}$. Thus,

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{PCl}_{5}\right]}{\left[\mathrm{PCl}_{3}\right]\left[\mathrm{Cl}_{2}\right]}=\frac{0.600}{(0.200)(0.125)}=24.0=K_{\mathrm{c}}
$$

Now we add enough $\mathrm{Cl}_{2}$ to increase its concentration by 0.075 M . Before any reaction occurs, this addition creates a new set of initial concentrations. Then the system reacts and comes to a new equilibrium position. From Le Châtelier's principle, we predict that adding more reactant will produce more product, that is, shift the equilibrium position to the right. Experiment shows that the new $\left[\mathrm{PCl}_{5}\right]$ at equilibrium is 0.637 M .

| Concentration (M) | $\mathrm{PCl}_{3}(\mathrm{~g})$ | + | $\mathrm{Cl}_{2}(\mathrm{~g})$ | $\rightleftharpoons$ | $\mathrm{PCl}_{5}(\mathrm{~g})$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Original equilibrium | 0.200 |  | 0.125 |  | 0.600 |
| Disturbance |  |  | +0.075 |  |  |
| New initial | 0.200 |  | 0.200 |  | 0.600 |
| Change | $x$ |  | -x |  | + $x$ |
| New equilibrium | $0.200-x$ |  | $0.200-x$ |  | $\begin{aligned} & 0.600+x \\ & (0.637)^{*} \end{aligned}$ |

[^26]Table 17.3 shows a reaction table of the entire process: the original equilibrium position, the disturbance, the (new) initial concentrations, the size and direction of the change needed to reattain equilibrium, and the new equilibrium position. Figure 17.8 depicts the process.

From Table 17.3,

Also,

$$
\left[\mathrm{PCl}_{5}\right]=0.600 M+x=0.637 M, \quad \text { so } \quad x=0.037 M
$$

Therefore, at equilibrium,

$$
\begin{aligned}
K_{\mathrm{c}(\text { original) }} & =\frac{0.600}{(0.200)(0.125)}=24.0 \\
K_{\mathrm{c}(\text { new })} & =\frac{0.637}{(0.163)(0.163)}=24.0
\end{aligned}
$$

There are several key points to notice about the new equilibrium concentrations that exist after $\mathrm{Cl}_{2}$ is added:

- As we predicted, $\left[\mathrm{PCl}_{5}\right]\left(0.637 \frac{N}{N}\right)$ is figher than its original concentration (0.600 M).
- $\left[\mathrm{Cl}_{2}\right](0.163 M)$ is higher than its original equilibrium concentration $(0.125 \mathrm{M})$, but lower than its initial concentration just after the addition $(0.200 \mathrm{M})$; thus, the disturbance (addition of $\mathrm{Cl}_{2}$ ) is reduced but not eliminated.
- $\left[\mathrm{PCl}_{3}\right](0.163 \mathrm{M})$, the other left-side component, is lower than its original concentration $(0.200 M)$ because some reacted with the added $\mathrm{Cl}_{2}$.
- Most importantly, although the position of equilibrium shifted to the right, $K_{c}$ remains the same.

Be sure to note that the system adjusts by changing concentrations, but the value of $K_{c}$ at a given temperature does not change with a change in concentration.

## SAMPLE PROBLEM 17.12 Predicting the Effect of a Change in

 Concentration on the Equilibrium PositionPROBLEM To improve air quality and obtain a useful product, chemists often remove sulfur from coal and natural gas by treating the fuel contaminant hydrogen sulfide with $\mathrm{O}_{2}$ :

$$
2 \mathrm{H}_{2} \mathrm{~S}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{~S}(s)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

What happens to
(a) $\left[\mathrm{H}_{2} \mathrm{O}\right]$ if $\mathrm{O}_{2}$ is added?
(b) $\left[\mathrm{H}_{2} \mathrm{~S}\right]$ if $\mathrm{O}_{2}$ is added?
(c) $\left[\mathrm{O}_{2}\right]$ if $\mathrm{H}_{2} \mathrm{~S}$ is removed?
(d) $\left[\mathrm{H}_{2} \mathrm{~S}\right]$ if sulfur is added?

PLAN We write the reaction quotient to see how $Q_{\mathrm{c}}$ is affected by each disturbance, relative to $K_{\mathrm{c}}$. This effect tells us the direction in which the reaction proceeds for the system to reattain equilibrium and how each concentration changes.

Figure 17.8 The effect of added $\mathrm{Cl}_{2}$ on the $\mathrm{PCl}_{3}-\mathrm{Cl}_{2}-\mathrm{PCl}_{5}$ system. In the original equilibrium (gray region), all concentrations are constant. When $\mathrm{Cl}_{2}$ (yellow curve) is added, its concentration jumps and then starts to fall as $\mathrm{Cl}_{2}$ reacts with some $\mathrm{PCl}_{3}$ to form more $\mathrm{PCl}_{5}$. After a period of time, equilibrium is re-established at new concentrations (blue region) but with the same $K$.

SOLUTION Writing the reaction quotient: $Q_{\mathrm{c}}=\frac{\left[\mathrm{H}_{2} \mathrm{O}\right]^{2}}{\left[\mathrm{H}_{2} \mathrm{~S}\right]^{2}\left[\mathrm{O}_{2}\right]}$
(a) When $\mathrm{O}_{2}$ is added, the denominator of $Q_{\mathrm{c}}$ increases, so $Q_{\mathrm{c}}<K_{\mathrm{c}}$. The reaction proceeds to the right until $Q_{\mathrm{c}}=K_{\mathrm{c}}$ again, so $\left[\mathrm{H}_{2} \mathrm{O}\right]$ increases.
(b) As in part (a), when $\mathrm{O}_{2}$ is added, $Q_{\mathrm{c}}<K_{\mathrm{c}}$. Some $\mathrm{H}_{2} \mathrm{~S}$ reacts with the added $\mathrm{O}_{2}$ as the reaction proceeds to the right, so $\left[\mathrm{H}_{2} \mathrm{~S}\right]$ decreases.
(c) When $\mathrm{H}_{2} \mathrm{~S}$ is removed, the denominator of $Q_{\mathrm{c}}$ decreases, so $Q_{\mathrm{c}}>K_{\mathrm{c}}$. As the reaction proceeds to the left to re-form $\mathrm{H}_{2} \mathrm{~S}$, more $\mathrm{O}_{2}$ is produced as well, so $\left[\mathrm{O}_{2}\right]$ increases.
(d) The concentration of solid S is unchanged as long as some is present, so it does not appear in the reaction quotient. Adding more S has no effect, so $\left[\mathrm{H}_{2} \mathrm{~S}\right]$ is unchanged (but see Comment 2 below).
CHECK Apply Le Châtelier's principle to see that the reaction proceeds in the direction that lowers the increased concentration or raises the decreased concentration.
COMMENT 1. As you know, sulfur exists most commonly as $S_{8}$. How would this change in formula affect the answers? The balanced equation and $Q_{\mathrm{c}}$ would be

$$
8 \mathrm{H}_{2} \mathrm{~S}(g)+4 \mathrm{O}_{2}(g) \rightleftharpoons \mathrm{S}_{8}(s)+8 \mathrm{H}_{2} \mathrm{O}(g) \quad Q_{\mathrm{c}}=\frac{\left[\mathrm{H}_{2} \mathrm{O}\right]^{8}}{\left[\mathrm{H}_{2} \mathrm{~S}\right]^{8}\left[\mathrm{O}_{2}\right]^{4}}
$$

The value of $K_{\mathrm{c}}$ is different for this equation, but the changes described in the problem have the same effects. For example, in (a), if $\mathrm{O}_{2}$ were added, the denominator of $Q_{\mathrm{c}}$ would increase, so $Q_{\mathrm{c}}<K_{\mathrm{c}}$. As above, the reaction would proceed to the right until $Q_{\mathrm{c}}=K_{\mathrm{c}}$ again. In other words, changes predicted by Le Châtelier's principle for a given reaction are not affected by a change in the balancing coefficients.
2. In (d), you saw that adding a solid has no effect on the concentrations of other components: because the concentration of the solid cannot change, it does not appear in $Q$. But the amount of solid can change. Adding $\mathrm{H}_{2} \mathrm{~S}$ shifts the reaction to the right, and more S forms.
FOLLOW-UP PROBLEM 17.12 In a study of the chemistry of glass etching, an inorganic chemist examines the reaction between sand $\left(\mathrm{SiO}_{2}\right)$ and hydrogen fluoride at a temperature above the boiling point of water:

$$
\mathrm{SiO}_{2}(s)+4 \mathrm{HF}(g) \rightleftharpoons \mathrm{SiF}_{4}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

Predict the effect on $\left[\mathrm{SiF}_{4}\right]$ when (a) $\mathrm{H}_{2} \mathrm{O}(g)$ is removed; (b) some liquid water is added; (c) HF is removed; (d) some sand is removed.

## The Effect of a Change in Pressure (Volume)

Changes in pressure have significant effects only on equilibrium systems with gaseous components. Aside from phase changes, a change in pressure has a negligible effect on liquids and solids because they are nearly incompressible. Pressure changes can occur in three ways:

- Changing the concentration of a gaseous component
- Adding an inert gas (one that does not take part in the reaction)
- Changing the volume of the reaction vessel

We just considered the effect of changing the concentration of a component, and that reasoning holds here. Next, let's see why adding an inert gas has no effect on the equilibrium position. Adding an inert gas does not change the volume, so all reactant and product concentrations remain the same. In other words, the volume and the number of moles of the reactant and product gases do not change, so their partial pressures do not change. Because we use these (unchanged) partial pressures in the reaction quotient, the equilibrium position cannot change. Moreover, the inert gas does not appear in $Q$, so it cannot have an effect.

On the other hand, changing the pressure by changing the volume often causes a large shift in the equilibrium position. Suppose we let the $\mathrm{PCl}_{3}-\mathrm{Cl}_{2}-\mathrm{PCl}_{5}$ system come to equilibrium in a cylinder-piston assembly. Then, we press down on the piston to halve the volume: the gas pressure immediately doubles. To reduce this increase in gas pressure, the system responds by reducing the number of gas molecules. And it does so in the only possible way-by shifting the reaction toward the side with fewer moles of gas, in this case, toward the product side:

$$
\begin{aligned}
\mathrm{PCl}_{3}(\mathrm{~g})+\mathrm{Cl}_{2}(\mathrm{~g}) & \longrightarrow \mathrm{PCl}_{5}(\mathrm{~g}) \\
2 \mathrm{~mol} \text { gas } & \longrightarrow 1 \mathrm{~mol} \text { gas }
\end{aligned}
$$

Notice that a change in volume results in a change in concentration: a decrease in container volume raises the concentration, and an increase in volume lowers the concentration. Recall that $Q_{\mathrm{c}}=\frac{\left[\mathrm{PCl}_{5}\right]}{\left[\mathrm{PCl}_{3}\right]\left[\mathrm{Cl}_{2}\right]}$. When the volume is halved, the concentrations double, but the denominator of $Q_{\mathrm{c}}$ is the product of two concentrations, so it quadruples while the numerator only doubles. Thus, $Q_{\mathrm{c}}$ becomes less than $K_{\mathrm{c}}$. As a result, the system forms more $\mathrm{PCl}_{5}$ and a new equilibrium position is reached. Because it is just another way to change the concentration, $a$ change in pressure due to a change in volume does not alter $K_{\mathrm{c}}$.

Thus, for a system that contains gases at equilibrium, in which the amount (mol) of gas, $n_{\text {gas }}$, changes during the reaction (Figure 17.9):

- If the volume becomes smaller (pressure is higher), the reaction shifts so that the total number of gas molecules decreases.
- If the volume becomes larger (pressure is lower), the reaction shifts so that the total number of gas molecules increases.

In many cases, however, $n_{\text {gas }}$ does not change $\left(\Delta n_{\text {gas }}=0\right)$. For example,

$$
\underset{2 \text { mol gas }}{\left.\mathrm{H}_{2}(\mathrm{~g})+\underset{2}{\boldsymbol{\lambda}(\mathrm{f}} \mathrm{f}\right) \underset{2 \mathrm{~mol} \text { gas }}{2 H(2)}}
$$

$Q_{\mathrm{c}}$ has the same number of terms in the numerator and denominator:

$$
Q_{\mathrm{c}}=\frac{[\mathrm{HI}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{I}_{2}\right]}=\frac{[\mathrm{HI}][\mathrm{HI}]}{\left[\mathrm{H}_{2}\right]\left[\mathrm{I}_{2}\right]}
$$

Therefore, a change in volume has the same effect on the numerator and denominator. Thus, if $\Delta n_{\text {gas }}=0$, there is no effect on the equilibrium position.

Figure 17.9 The effect of pressure (volume) on a system at equilibrium. The system of gases
(center) is at equilibrium. For the reaction
an increase in pressure (right) decreases the volume, so the reaction shifts to the right to make fewer molecules. A decrease in pressure (left) increases the volume, so the reaction shifts to the left to make more molecules.

## SAMPLE PROBLEM 17.13 Predicting the Effect of a Change in Volume (Pressure) on the Equilibrium Position

PROBLEM How would you change the volume of each of the following reactions to increase the yield of the products?
(a) $\mathrm{CaCO}_{3}(s) \rightleftharpoons \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)$
(b) $\mathrm{S}(s)+3 \mathrm{~F}_{2}(g) \rightleftharpoons \mathrm{SF}_{6}(g)$
(c) $\mathrm{Cl}_{2}(g)+\mathrm{I}_{2}(g) \rightleftharpoons 2 \mathrm{ICl}(g)$

PLAN Whenever gases are present, a change in volume causes a change in concentration. For reactions in which the number of moles of gas changes, if the volume decreases (pressure increases), the equilibrium position shifts to relieve the pressure by reducing the number of moles of gas. A volume increase (pressure decrease) has the opposite effect.
SOLUTION (a) The only gas is the product $\mathrm{CO}_{2}$. To make the system produce more $\mathrm{CO}_{2}$, we increase the volume (decrease the pressure).
(b) With 3 mol of gas on the left and only 1 mol on the right, we decrease the volume (increase the pressure) to form more $\mathrm{SF}_{6}$.
(c) The number of moles of gas is the same on both sides of the equation, so a change in volume (pressure) will have no effect on the yield of ICl.
CHECK Let's predict the relative values of $Q_{\mathrm{c}}$ and $K_{\mathrm{c}}$. In (a), $Q_{\mathrm{c}}=\left[\mathrm{CO}_{2}\right]$, so increasing the volume will make $Q_{\mathrm{c}}<K_{\mathrm{c}}$, and the system will make more $\mathrm{CO}_{2}$. In (b), $Q_{\mathrm{c}}=$ $\left[\mathrm{SF}_{6}\right] /\left[\mathrm{F}_{2}\right]^{3}$. Lowering the volume increases $\left[\mathrm{F}_{2}\right]$ and $\left[\mathrm{SF}_{6}\right]$ proportionately, but $Q_{\mathrm{c}}$ decreases because of the exponent 3 in the denominator. To make $Q_{\mathrm{c}}=K_{\mathrm{c}}$ again, $\left[\mathrm{SF}_{6}\right]$ must increase. In (c), $Q_{\mathrm{c}}=[\mathrm{ICl}]^{2} /\left[\mathrm{Cl}_{2}\right]\left[\mathrm{I}_{2}\right]$. A change in volume (pressure) affects the numerator ( 2 mol ) and denominator ( 2 mol ) equally, so it will have no effect.
FOLLOW-UP PROBLEM 17.13 Would you increase or decrease the pressure (via a volume change) of each of the following reaction mixtures to decrease the yield of products?
(a) $2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{SO}_{3}(g)$
(b) $4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) \rightleftharpoons 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)$
(c) $\mathrm{CaC}_{2} \mathrm{O}_{4}(s) \rightleftharpoons \mathrm{CaCO}_{3}(s)+\mathrm{CO}(g)$

## 

Of the three types of disturbances-a change in concentration, in pressure, or in temperature-only temperature changes alter $K$. To see why, we must take the heat of reaction into account:

$$
\mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g) \rightleftharpoons \mathrm{PCl}_{5}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-111 \mathrm{~kJ}
$$

The forward reaction is exothermic (releases heat; $\Delta H^{\circ}<0$ ), so the reverse reaction is endothermic (absorbs heat; $\Delta H^{\circ}>0$ ):

$$
\begin{aligned}
& \mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g) \longleftrightarrow \mathrm{PCl}_{5}(g)+\text { heat } \text { (exothermic) } \\
& \mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g) \longleftrightarrow \mathrm{PCl}_{5}(g)+\text { heat } \text { (endothermic) }
\end{aligned}
$$

If we consider heat as a component of the equilibrium system, a rise in temperature occurs when heat is "added" to the system and a drop in temperature occurs when heat is "removed" from the system. As with a change in any other component, the system shifts to reduce the effect of the change. Therefore, a temperature increase (adding heat) favors the endothermic (heat-absorbing) direction, and a temperature decrease (removing heat) favors the exothermic (heat-releasing) direction.

If we start with the system at equilibrium, $Q$ equals $K$. Increase the temperature, and the system responds by decomposing some $\mathrm{PCl}_{5}$ to $\mathrm{PCl}_{3}$ and $\mathrm{Cl}_{2}$, which absorbs the added heat. The denominator of $Q$ becomes larger and the numerator smaller, so the system reaches a new equilibrium position at a smaller ratio of concentration terms, that is, a lower $K$. Similarly, the system responds to a drop in temperature by forming more $\mathrm{PCl}_{5}$ from some $\mathrm{PCl}_{3}$ and $\mathrm{Cl}_{2}$, which releases more heat. The numerator of $Q$ becomes larger, the denominator smaller, and the new equilibrium position has a higher $K$. Thus,

- A temperature rise will increase $K$ for a system with a positive $\Delta H_{\mathrm{rxn}}^{\circ}$.
- A temperature rise will decrease $K$ for a system with a negative $\Delta H_{\mathrm{rxn}}^{\circ}$.

Let's review these ideas with a sample problem.

## SAMPLE PROBLEM 17.14 Predicting the Effect of a Change in Temperature on the Equilibrium Position

PROBLEM How does an increase in temperature affect the equilibrium concentration of the underlined substance and $K$ for each of the following reactions?
(a) $\mathrm{CaO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \underline{\mathrm{Ca}(\mathrm{OH})_{2}(a q) \quad \Delta H^{\circ}=-82 \mathrm{~kJ}, ~}$
(b) $\mathrm{CaCO}_{3}(s) \rightleftharpoons \mathrm{CaO}(s)+\mathrm{CO}_{2}(g) \quad \Delta H^{\circ}=178 \mathrm{~kJ}$
(c) $\underline{\mathrm{SO}_{2}}(g) \rightleftharpoons \mathrm{S}(s)+\mathrm{O}_{2}(g) \quad \Delta H^{\circ}=297 \mathrm{~kJ}$

PLAN We write each equation to show heat as a reactant or product. The temperature increases when we add heat, so the system shifts to absorb the heat; that is, the endothermic reaction occurs. Thus, $K$ will increase if the forward reaction is endothermic and decrease if it is exothermic.
SOLUTION (a) $\mathrm{CaO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{Ca}(\mathrm{OH})_{2}(a q)+$ heat
Adding heat shifts the system to the left: $\left[\mathrm{Ca}(\mathrm{OH})_{2}\right]$ and $K$ will decrease.
(b) $\mathrm{CaCO}_{3}(s)+$ heat $\rightleftharpoons \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)$

Adding heat shifts the system to the right: $\left[\mathrm{CO}_{2}\right]$ and $K$ will increase.
(c) $\mathrm{SO}_{2}(g)+$ heat $\rightleftharpoons \mathrm{S}(s)+\mathrm{O}_{2}(g)$

Adding heat shifts the system to the right: $\left[\mathrm{SO}_{2}\right]$ will decrease and $K$ will increase.
CHECK You can check your answers by going through the reasoning for a decrease in temperature: heat is removed and the exothermic direction is favored. All the answers should be opposite.
FOLLOW-UP PROBLEM 17.14 How does a decrease in temperature affect the partial pressure of the underlined substance and the value of $K$ for each of the following reactions?
(a) C (graphite) $+2 \underline{\mathrm{H}_{2}}(g) \rightleftharpoons \mathrm{CH}_{4}(g) \quad \Delta H^{\circ}=-75 \mathrm{~kJ}$
(b) $\underline{\mathrm{N}_{2}}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}(g) \quad \Delta H^{\circ}=181 \mathrm{~kJ}$
(c) $\mathrm{P}_{4}(s)+10 \mathrm{Cl}_{2}(g) \rightleftharpoons 4 \mathrm{PCl}_{5}(g) \quad \Delta H^{\circ}=-1528 \mathrm{~kJ}$

The van't Hoff Equation: The Effect of $\boldsymbol{T}$ on $\boldsymbol{K}$ The van't Hoff equation shows how the equilibrium constant is affected by changes in temperature:

$$
\begin{equation*}
\ln \frac{K_{2}}{K_{1}}=-\frac{\Delta H_{\mathrm{rxn}}^{\circ}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right) \tag{17.10}
\end{equation*}
$$

where $K_{1}$ is the equilibrium constant at $T_{1}, K_{2}$ is the equilibrium constant at $T_{2}$, and $R$ is the universal gas constant $(8.314 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{K})$. If we know $\Delta H_{\mathrm{rxn}}^{\circ}$ and $K$ at one temperature, the van't Hoff equation allows us to find $K$ at any other temperature (or to find $\Delta H_{\mathrm{rxn}}^{\circ}$, given the two $K$ 's at two $T$ 's).

Here's a typical problem that requires the van't Hoff equation. Coal gasification processes usually begin with the formation of syngas from carbon and steam:

$$
\mathrm{C}(s)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons \mathrm{CO}(g)+\mathrm{H}_{2}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=131 \mathrm{~kJ} / \mathrm{mol}
$$

An engineer knows that $K_{\mathrm{p}}$ is only $9.36 \times 10^{-17}$ at $25^{\circ} \mathrm{C}$ and therefore wants to find a temperature that allows a much higher yield. Calculate $K_{\mathrm{p}}$ at $700^{\circ} \mathrm{C}$.

$$
\ln \frac{K_{2}}{K_{1}}=-\frac{\Delta H_{\mathrm{rxn}}^{\circ}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right)
$$

The temperatures must be converted, and we make the units of $\Delta H^{\circ}$ and $R$ consistent:

$$
\begin{aligned}
\ln \left(\frac{K_{\mathrm{p} 2}}{9.36 \times 10^{-17}}\right) & =-\frac{131 \times 10^{3} \mathrm{~J} / \mathrm{mol}}{8.314 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K}}\left(\frac{1}{973 \mathrm{~K}}-\frac{1}{298 \mathrm{~K}}\right) \\
\frac{K_{\mathrm{p} 2}}{9.36 \times 10^{-17}} & =8.51 \times 10^{15} \\
K_{\mathrm{p} 2} & =0.797
\end{aligned}
$$

## Temperature-DependentSystem There

 is a striking similarity among expressions for the temperature dependence of $K, k$ (rate constant), and $P$ (equilibrium vapor pressure):$$
\begin{aligned}
& \ln \frac{K_{2}}{K_{1}}=-\frac{\Delta H_{\mathrm{rxn}}^{\circ}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right) \\
& \ln \frac{k_{2}}{k_{1}}=-\frac{E_{\mathrm{a}}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right) \\
& \ln \frac{P_{2}}{P_{1}}=-\frac{\Delta H_{\text {vap }}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right)
\end{aligned}
$$

Each concentration-related term ( $K, k$, or $P$ ) is dependent on $T$ through an energy term $\left(\Delta H_{\mathrm{rxn}}^{\circ}, E_{\mathrm{a}}\right.$, or $\Delta H_{\text {vap }}$, respectively) divided by $R$. The similarity arises because the equations express the same relationship. $K$ equals a ratio of rate constants, and $E_{\mathrm{a}(\mathrm{fwd})}-E_{\mathrm{a}(\mathrm{rev})}=\Delta H_{\mathrm{rxn}}^{\circ}$. In the vapor pressure case, for the phase change $\mathrm{A}(l) \rightleftharpoons \mathrm{A}(g)$, the heat of reaction is equal to the heat of vaporization: $\Delta H_{\text {vap }}=\Delta H_{\mathrm{rxn}}^{\circ}$. Also, the equilibrium constant equals the equilibrium vapor pressure: $K_{\mathrm{p}}=P_{\mathrm{A}}$.

Catalyzed Perpetual Motion? This engine consists of a piston attached to a flywheel, whose rocker arm holds a catalyst and moves in and out of the reaction in the cylinder. What if the catalyst could increase the rate of $\mathrm{PCl}_{5}$ breakdown but not of its formation? In the cylinder, the catalyst would speed up the breakdown of $\mathrm{PCl}_{5}$ to $\mathrm{PCl}_{3}$ and $\mathrm{Cl}_{2}-1 \mathrm{~mol}$ of gas to 2 mol-increasing gas pressure and pushing the piston out. With the catalyst out of the cylinder, $\mathrm{PCl}_{3}$ and $\mathrm{Cl}_{2}$ would re-form $\mathrm{PCl}_{5}$, lowering gas pressure and moving the piston in. The process would supply power with no input of external energy. If a catalyst could change the rate in only one direction, it would change $K$, and we could design some amazing machines!

Equation 17.10 confirms the qualitative prediction from Le Châtelier's principle: for a temperature rise, we have

$$
T_{2}>T_{1} \quad \text { and } \quad 1 / T_{2}<1 / T_{1}, \quad \text { so } 1 / T_{2}-1 / T_{1}<0
$$

Therefore,

- For an endothermic reaction $\left(\Delta H_{\mathrm{rxn}}^{\circ}>0\right)$, the $-\left(\Delta H_{\mathrm{rxn}}^{\circ} / R\right)$ term is $<0$. With $1 / T_{2}-1 / T_{1}<0$, the right side of the equation is $>0$. Thus, $\ln \left(K_{2} / K_{1}\right)>0$, so $K_{2}>K_{1}$.
- For an exothermic reaction $\left(\Delta H_{\mathrm{rxn}}^{\circ}<0\right)$, the $-\left(\Delta H_{\mathrm{rxn}}^{\circ} / R\right)$ term is $>0$. With $1 / T_{2}-1 / T_{1}<0$, the right side of the equation is $<0$. Thus, $\ln \left(K_{2} / K_{1}\right)<0$, so $K_{2}<K_{1}$.
(For further practice with the van't Hoff equation, see Problems 17.73 and 17.74.)

## The Lack of Effect of a Catalyst

Let's briefly consider a final external change to the reacting system: adding a catalyst. Recall from Chapter 16 that a catalyst speeds up a reaction by providing an alternative mechanism with a lower activation energy, thereby increasing the forward and reverse rates to the same extent. In other words, it shortens the time needed to attain the final concentrations. Thus, a catalyst shortens the time it takes to reach equilibrium but has no effect on the equilibrium position.

If, for instance, we add a catalyst to a mixture of $\mathrm{PCl}_{3}$ and $\mathrm{Cl}_{2}$ at 523 K , the system will attain the same equilibrium concentrations of $\mathrm{PCl}_{3}, \mathrm{Cl}_{2}$, and $\mathrm{PCl}_{5}$ more quickly than it did without the catalyst. As you'll see in a moment, however, catalysts often play key roles in optimizing reaction systems.

Table 17.4 summarizes the effects of changing conditions on the position of equilibrium. Note that many changes alter the equilibrium position, but only temperame. ¢hanges ater the vatuerne equibrium constant. Sample Problem 17.15 shows how to visualize equilibrium at the molecular level. Then, two Chemical Connections essays apply equilibrium principles: the first examines metabolic processes in organisms, and the second describes a major industrial process.

## SAMPLE PROBLEM 17.15 Determining Equilibrium Parameters from Molecular Scenes

PROBLEM For the reaction,

$$
\mathrm{X}(g)+\mathrm{Y}_{2}(g) \rightleftharpoons \mathrm{XY}(g)+\mathrm{Y}(g) \quad \Delta H>0
$$

the following molecular scenes depict different reaction mixtures ( X is green, Y is purple):

(a) If $K=2$ at the temperature of the reaction, which scene represents the mixture at equilibrium? (b) Will the reaction mixtures in the other two scenes proceed toward reactants or toward products to reach equilibrium? (c) For the mixture at equilibrium, how will a rise in temperature affect $\left[\mathrm{Y}_{2}\right]$ ?
PLAN (a) We are given the balanced equation and the value of $K$ and must choose the scene representing the mixture at equilibrium. We write the expression for $Q$, and for each scene, count particles and plug in the numbers to solve for the value of $Q$. Whichever scene gives a $Q$ equal to $K$ represents the mixture at equilibrium. (b) To determine the direction each reaction proceeds in the other two scenes, we compare the value of $Q$ with the given $K$. If $Q>K$, the numerator (product side) is too high, so the reaction proceeds toward reactants; if $Q<K$, the reaction proceeds toward products. (c) We are given the sign of $\Delta H$ and must see whether a rise in $T$ (corresponding to supplying heat) will increase or decrease the amount of the reactant $\mathrm{Y}_{2}$. We treat heat as a reactant or product and see whether adding heat shifts the reaction right or left.
SOLUTION (a) For the reaction, we have $Q=\frac{[\mathrm{XY}][\mathrm{Y}]}{[\mathrm{X}]\left[\mathrm{Y}_{2}\right]}$. Thus,
scene 1: $Q=\frac{5 \times 3}{1 \times 1}=15 \quad$ scene 2: $Q=\frac{4 \times 2}{2 \times 2}=2 \quad$ scene 3: $Q=\frac{3 \times 1}{3 \times 3}=\frac{1}{3}$
For scene $2, Q=K$, so scene 2 represents the mixture at equilibrium.
(b) For scene $1, Q(15)>K$ (2), so the reaction proceeds toward reactants.

For scene $3, Q\left(\frac{1}{3}\right)<K(2)$, so the reaction proceeds toward products.
(c) The reaction is endothermic, so heat acts as a reactant:

$$
\mathrm{X}(g)+\mathrm{Y}_{2}(g)+\text { heat } \rightleftharpoons \mathrm{XY}(g)+\mathrm{Y}(g)
$$

Therefore, adding heat to the left shifts the reaction to the right, so $\left[\mathrm{Y}_{2}\right]$ decreases.
CHECK (a) Remember that quantities in the numerator (or denominator) of $Q$ are multiplied, not added. For example, the denominator for scene 1 is $1 \times 1=1$, not $1+1=2$.
(c) A good check is to imagine that $\Delta H<0$ and see if you get the opposite result:

$$
\mathrm{X}(g)+\mathrm{Y}_{2}(g) \rightleftharpoons \mathrm{XY}(g)+\mathrm{Y}(g)+\text { heat }
$$

If $\Delta H<0$, adding heat would shift the reaction to the left and increase [ $\mathrm{Y}_{2}$ ].
FOLLOW-UP PROBLEM 17.15 For the reaction

$$
\mathrm{C}_{2}(g)+\mathrm{D}_{2}(g) \rightleftharpoons 2 \mathrm{CD}(g) \quad \Delta H<0
$$

these molecular scenes depict different reaction mixtures ( C is red, D is blue):

(a) Calculate the value of $K_{\mathrm{p}}$. (b) In which direction will the reaction proceed for the mixtures not at equilibrium? (c) For the mixture at equilibrium, what effect will a rise in $T$ have on the total moles of gas (increase, decrease, no effect)? Explain.

# Design and Control of a Metabolic Pathway 

Biological cells are microscopic wizards of chemical change. From the simplest bacterium to the most specialized neuron, every cell performs thousands of individual reactions that allow it to grow and reproduce, feed and excrete, move and communicate. Taken together, these chemical reactions constitute the cell's metabolism. These myriad feats of biochemical breakdown, synthesis, and energy flow are organized into reaction sequences called metabolic pathways. Some pathways disassemble the biopolymers in food into monomer building blocks: sugars, amino acids, and nucleotides. Others extract energy from these small molecules and then use much of the energy to assemble molecules with other functions, such as hormones, neurotransmitters, defensive toxins, and the cell's own biopolymers.

In principle, each step in a metabolic pathway is a reversible reaction catalyzed by a specific enzyme (Section 16.8). However, equilibrium is never reached in a pathway. As in other reaction sequences, the product of the first reaction becomes the reactant of the second, the product of the second becomes the reactant of the third, and so on. Consider the five-step pathway shown in Figure B17.1, in which one amino acid, threonine, is converted into another, isoleucine, in the cells of a bread mold. Threonine, supplied from a different region of the cell, forms ketobutyrate through the catalytic action of the first enzyme (reaction 1). The equilibrium position of reaction 1 continuously shifts to the right because the ketobutyrate is continuously removed as the reactant in reaction 2 . Similarly, reaction 2 shifts to the right as its product is used in reaction 3. Each subsequent reaction shifts the equilibrium position of the previous reaction in the direction of producDmegin product, isoleucine, is typically removed to make proteins elsewhere in the cell. Thus, the entire pathway operates in one direction.

This continuous shift in equilibrium position results in two major features of metabolic pathways. First, each step proceeds with nearly $100 \%$ yield: Virtually every molecule of threonine that enters this region of the cell eventually changes to ketobutyrate, every molecule of ketobutyrate to the next product, and so on.

Second, reactant and product concentrations remain constant or vary within extremely narrow limits, even though the system never attains equilibrium. This situation, called a steady state, is different in a basic way from those we have studied so far. In equilibrium systems, equal reaction rates in opposing directions give rise to constant concentrations of reactants and products. In steady-state systems, on the other hand, the rates of reactions in one direction-into, through, and out of the system-give rise to nearly constant concentrations of intermediates. Ketobutyrate, for example, is formed via reaction 1 just as fast as it is used via reaction 2, so its concentration is kept constant. (You can establish a
steady-state amount of water by filling a sink and then adjusting the faucet and drain so that water enters just as fast as it leaves.)

It is critical that a cell regulate the concentration of the final product of a pathway. Recall from Chapter 16 that an enzyme catalyzes a reaction when the substrate (reactant) occupies the active site. However, substrate concentrations are so much higher than enzyme concentrations that, if no other factors were involved, the active sites on all the enzyme molecules would always be occupied and all cellular reactions would occur at their maximum rates. This might be ideal for an industrial process, but it could be catastrophic for an organism. To regulate overall product formation, the rates of certain key steps are controlled by regulatory enzymes, which contain an inhibitor site on their surface in addition to an active site. The enzyme's three-dimensional structure is such that when the inhibitor site is occupied, the shape of the active site is deformed and the reaction cannot be catalyzed (Figure B17.2).

In the simplest case of metabolic control (Figure B17.1), the final product of the pathway is also the inhibitor molecule, and the regulatory enzyme catalyzes the first step. Suppose, for instance, that a bread mold cell is temporarily making less protein, so the isoleucine synthesized by the pathway in Figure B17.1 is not being removed as quickly. As the concentration of isoleucine rises, the chance increases that an isoleucine molecule will land on the inhibitor site of the first enzyme in the pathway, thereby inhibiting its own production. This process is called end-product feedback inhibition. More complex pathways have more elaborate regulatory schemes, but many operate through similar types of inPhibitor hfeaback (seepeoblem 17.113). The exquisitely detailed regulation of a cell's numerous metabolic pathways arises directly from the principles of chemical kinetics and equilibrium.

Figure B17.2 Effect of inhibitor binding on shape of active site. A, If inhibitor site is not occupied, the enzyme catalyzes the reaction. B, If inhibitor site is occupied, the enzyme molecule does not function.

Figure B17.1 The biosynthesis of isoleucine from threonine. Isoleucine is synthesized from threonine in a sequence of five enzymecatalyzed reactions. The unequal equilibrium arrows show that each step is reversible but is shifted toward product as each product be-
comes the reactant of the subsequent step. When the cell's need for isoleucine is temporarily satisfied, the concentration of isoleucine, the end product, builds up and inhibits the catalytic activity of threonine dehydratase, the first enzyme in the pathway.

## Chemical Connections to Industrial Production The Haber Process for the Synthesis of Ammonia

Nitrogen occurs in many essential natural and synthetic compounds. By far the richest source of nitrogen is the atmosphere, where four of every five molecules are $\mathrm{N}_{2}$. Despite this abundance, the supply of usable nitrogen for biological and manufacturing processes is limited because of the low chemical reactivity of $\mathrm{N}_{2}$. Because of the strong triple bond holding the two N atoms together, the nitrogen atom is very difficult to "fix," that is, to combine with other atoms.

Natural nitrogen fixation occurs either through the elegant specificity of enzymes found in bacteria that live on plant roots or through the brute force of lightning. Nearly $13 \%$ of nitrogen fixation on Earth is accomplished industrially through the Haber process for the formation of ammonia from its elements:

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-91.8 \mathrm{~kJ}
$$

The process was developed by the German chemist Fritz Haber and first used in 1913. From its humble beginnings in a plant with a capacity of 12,000 tons a year, world production of ammonia has exploded to a current level of more than 110 million tons a year. On a mole basis, more ammonia is produced industrially than any other compound. Over $80 \%$ of this ammonia is used in fertilizer applications. In fact, the most common form of fertilizer is compressed anhydrous, liquid $\mathrm{NH}_{3}$ injected directly into the soil (Figure B17.3). Other uses of $\mathrm{NH}_{3}$ include the production of explosives, via the formation of $\mathrm{HNO}_{3}$, and the making of nylons and other polymers. Smaller amounts are used as refrigerants, rubber stabilizers, and household cleaners and in the synthesis of pharmaceuticals and other organic chemicals.

The Haber process provides an excelent èportinity Poaply equilibrium principles and see the compromises needed to make an industrial process economically worthwhile. From inspection of the balanced equation, we can see three ways to maximize the yield of ammonia:

1. Decrease $\left[\mathrm{NH}_{3}\right]$. Ammonia is the product, so removing it as it forms will make the system produce more in a continual drive to reattain equilibrium.

Figure B17.3 Liquid ammonia used as fertilizer.

| Table B17.1 <br> Effect of Temperature on <br> for Ammonia Synthesis <br> $\boldsymbol{T}(\boldsymbol{K})$ | $\boldsymbol{K}_{\boldsymbol{c}}$ |
| :---: | :---: |
| 200. | $7.17 \times 10^{15}$ |
| 300. | $2.69 \times 10^{8}$ |
| 400. | $3.94 \times 10^{4}$ |
| 500. | $1.72 \times 10^{2}$ |
| 600. | $4.53 \times 10^{0}$ |
| 700. | $2.96 \times 10^{-1}$ |
| 800. | $3.96 \times 10^{-2}$ |

2. Decrease volume (increase pressure). Because 4 mol of gas reacts to form 2 mol of gas, decreasing the volume will shift the equilibrium position toward fewer moles of gas, that is, toward ammonia formation.
3. Decrease temperature. Because the formation of ammonia is exothermic, decreasing the temperature (removing heat) will shift the equilibrium position toward the product, thereby increasing $K_{\mathrm{c}}$ (Table B17.1).
Therefore, the ideal conditions for maximizing the yield of ammonia are continual removal of $\mathrm{NH}_{3}$ as it forms, high pressure, and low temperature. Figure B17.4 shows the percent yield of ammonia at various conditions of pressure and temperature. Note the Fatmosteqmetetecenversion (98.3\%) to ammonia at 1000 atm and the relatively low temperature of $473 \mathrm{~K}\left(200 .{ }^{\circ} \mathrm{C}\right)$.

Unfortunately, a problem arises that highlights the distinction between the principles of equilibrium and kinetics. Although the yield is favored by low temperature, the rate of formation is not. In fact, ammonia forms so slowly at low temperatures that the process becomes uneconomical. In practice, a compromise is achieved that optimizes yield and rate. High pressure and continuous removal are used to increase yield, but the temperature is
(continued)

Figure B17.4 Percent yield of ammonia vs. temperature $\left({ }^{\circ} \mathrm{C}\right)$ at five different operating pressures. At very high pressure and low temperature (top left), the yield is high, but the rate of formation is low. Industrial conditions (circle) are between 200 and 300 atm at about $400^{\circ} \mathrm{C}$.
raised to a moderate level and a catalyst is used to increase the rate. Achieving the same rate without employing a catalyst would require much higher temperatures and would result in a much lower yield.

The stages in the industrial production of ammonia are shown schematically in Figure B17.5. To extend equipment life and minimize cost, modern ammonia plants operate at pressures of about 200 to 300 atm and temperatures of around $673 \mathrm{~K}\left(400 .{ }^{\circ} \mathrm{C}\right)$. The catalyst consists of $5-\mathrm{mm}$ to $10-\mathrm{mm}$ chunks of iron crystals embedded in a fused mixture of $\mathrm{MgO}, \mathrm{Al}_{2} \mathrm{O}_{3}$, and $\mathrm{SiO}_{2}$. The stoi-
chiometric ratio of compressed reactant gases $\left(\mathrm{N}_{2} / \mathrm{H}_{2}=1 / 3\right.$ by volume) is injected into the heated, pressurized reaction chamber, where it flows over the catalyst beds. Some of the heat needed is supplied by the enthalpy change of the reaction. The emerging equilibrium mixture, which contains about $35 \% \mathrm{NH}_{3}$ by volume, is cooled by refrigeration coils until the $\mathrm{NH}_{3}$ (boiling point, $-33.4^{\circ} \mathrm{C}$ ) condenses and is removed. Because $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ have much lower boiling points than $\mathrm{NH}_{3}$, they remain gaseous and are recycled by pumps back into the reaction chamber to continue the process.

Figure B17.5 Key stages in the Haber process for synthesizing ammonia.

## Apago PDF Enhancer

## Section Summary

Le Châtelier's principle states that if a system at equilibrium is disturbed, the system undergoes a net reaction that reduces the disturbance and allows equilibrium to be reattained. - Changes in concentration cause a net reaction away from the added component or toward the removed component. For a reaction that involves a change in number of moles of gas, an increase in pressure (decrease in volume) causes a net reaction toward fewer moles of gas, and a decrease in pressure causes the opposite change. Although the equilibrium concentrations of components change as a result of concentration and volume changes, $K$ does not change. - A temperature change does change $K$ : higher $T$ increases $K$ for an endothermic reaction (positive $\Delta H_{r \times n}^{\circ}$ ) and decreases $K$ for an exothermic reaction (negative $\Delta H_{r x n}^{\circ}$ ). • A catalyst causes the system to reach equilibrium more quickly by speeding forward and reverse reactions equally, but it does not affect the equilibrium position. - A metabolic pathway is a cellular reaction sequence in which each step is shifted completely toward product. Its overall yield is controlled by feedback inhibition of certain key enzymes. - Ammonia is produced in a process favored by high pressure, low temperature, and continual removal of product. To make the process economical, an intermediate temperature and a catalyst are used.

## Chapter Perspective

The equilibrium phenomenon is central to all natural systems. In this introduction, which focused primarily on gaseous systems, we discussed the nature of equilibrium on the observable and molecular levels, ways to solve relevant problems, and how conditions affect systems at equilibrium. In Chapters 18 and 19, we apply these ideas to acids and bases and to other aqueous ionic systems. Then we examine the fundamental relationship between the equilibrium constant and the energy change that accompanies a reaction to understand why chemical reactions occur.

## CHAPTER REVIEW GUIDE

 The following sections provide many aids to help you study this chapter. (Numbers in parentheses refer to pages, unless noted otherwise.)
## Learning Objectives These are concepts and skills you should know after studying this chapter.

Relevant section and/or sample problem (SP) numbers appear in parentheses.

## Understand These Concepts

1. The distinction between the speed (rate) and the extent of a reaction (Introduction)
2. Why a system attains dynamic equilibrium when forward and reverse reaction rates are equal (Section 17.1)
3. The equilibrium constant as a number that is equal to a particular ratio of rate constants and of concentration terms (Section 17.1) 4. How the magnitude of $K$ is related to the extent of the reaction (Section 17.1)
4. Why the same equilibrium state is reached no matter what the starting concentrations of the reacting system (Section 17.2)
5. How the reaction quotient $(Q)$ changes continuously until the system reaches equilibrium, at which point $Q=K$ (Section 17.2) 7. Why the form of $Q$ is based exactly on the balanced equation as written (Section 17.2)
6. How the sum of reaction steps gives the overall reaction, and the product of $Q$ 's (or $K$ 's) gives the overall $Q$ (or $K$ ) (Section 17.2)
7. Why pure solids and liquids do not appear in $Q$ (Section 17.2)
8. How the interconversion of $K_{\mathrm{c}}$ and $K_{\mathrm{p}}$ is based on the ideal gas law and $\Delta n_{\text {gas }}$ (Section 17.3)
9. How the reaction direction depends on the relative values of $Q$ and $K$ (Section 17.4)
10. How a reaction table is used to findoan ukfown Pquafty (concentration or pressure) (Section 17.5)
11. How assuming that the change in [reactant] is relatively small simplifies finding equilibrium quantities (Section 17.5)
12. How Le Châtelier's principle explains the effects of a change in concentration, pressure (volume), or temperature on a system at equilibrium and on $K$ (Section 17.6)
13. Why a change in temperature does affect $K$ (Section 17.6)
14. Why the addition of a catalyst does not affect $K$ (Section 17.6)

## Master These Skills

1. Writing the reaction quotient $(Q)$ from a balanced equation (SP 17.1)
2. Writing $Q$ and calculating $K$ for a reaction consisting of more than one step (SP 17.2)
3. Writing $Q$ and finding $K$ for a reaction multiplied by a common factor (SP 17.3)
4. Writing $Q$ for heterogeneous equilibria (Section 17.2)
5. Converting between $K_{\mathrm{c}}$ and $K_{\mathrm{p}}$ (SP 17.4)
6. Comparing $Q$ and $K$ to determine reaction direction (SPs 17.5, 17.6)
7. Substituting quantities (concentrations or pressures) into $Q$ to find $K$ (Section 17.5)
8. Using a reaction table to determine quantities and find $K$ (SP 17.7)
9. Finding one equilibrium quantity from other equilibrium quantities and $K$ (SP 17.8)
10. Finding an equilibrium quantity from initial quantities and $K$ (SP 17.9)
11. Solving a quadratic equation for an unknown equilibrium quantity (Section 17.5)
12. Assuming that the change in [reactant] is relatively small to find equilibrium quantities and checking the assumption (SP 17.10)
13. Comparing the values of $Q$ and $K$ to find reaction direction and $x$, the unknown change in a quantity (SP 17.11)
14. Using the relative values of $Q$ and $K$ to predict the effect of Fachange in concentration on the equilibrium position and on $K$
15. Using Le Châtelier's principle and $\Delta n_{\text {gas }}$ to predict the effect of a change in pressure (volume) on the equilibrium position (SP 17.13)
16. Using Le Châtelier's principle and $\Delta H^{\circ}$ to predict the effect of a change in temperature on the equilibrium position and on $K$ (SP 17.14)
17. Using the van't Hoff equation to calculate $K$ at one temperature given $K$ at another temperature (Section 17.6)
18. Using molecular scenes to find equilibrium parameters (SP 17.15)

Key Terms These important terms appear in boldface in the chapter and are defined again in the Glossary.

Section 17.1
equilibrium constant $(K)(740)$

## Section 17.2

law of chemical equilibrium (law of mass action) (741) reaction quotient $(Q)(741)$

## Section 17.6

Le Châtelier's principle (761)
metabolic pathway (770)
Haber process (771)

## Key Equations and Relationships Numbered and screened concepts are listed for you to refer to or memorize.

17.1 Defining equilibrium in terms of reaction rates (739): At equilibrium: rate $_{\mathrm{fwd}}=$ rate $_{\mathrm{rev}}$
17.2 Defining the equilibrium constant for the reaction
$\mathrm{A} \rightleftharpoons 2 \mathrm{~B}$ (740):

$$
K=\frac{k_{\mathrm{fwd}}}{k_{\mathrm{rev}}}=\frac{[\mathrm{B}]_{\mathrm{eq}}^{2}}{[\mathrm{~A}]_{\mathrm{eq}}}
$$

17.3 Defining the equilibrium constant in terms of the reaction quotient (741):

At equilibrium: $Q=K$
17.4 Expressing $Q_{\mathrm{c}}$ for the reaction $a \mathrm{~A}+b \mathrm{~B} \rightleftharpoons c \mathrm{C}+d \mathrm{D}(742)$ :

$$
Q_{\mathrm{c}}=\frac{[\mathrm{C}]^{c}[\mathrm{D}]^{d}}{[\mathrm{~A}]^{a}[\mathrm{~B}]^{b}}
$$

## Key Equations and Relationships (continued)

17.5 Finding the overall $K$ for a reaction sequence (743):

$$
K_{\text {overall }}=K_{1} \times K_{2} \times K_{3} \times \cdots
$$

17.6 Finding $K$ of a reaction from $K$ of the reverse reaction (745):

$$
K_{\mathrm{fwd}}=\frac{1}{K_{\mathrm{rev}}}
$$

17.7 Finding $K$ of a reaction multiplied by a factor $n$ (745):

$$
K^{\prime}=K^{n}
$$

17.8 Relating $K$ based on pressures to $K$ based on concentrations (749):

$$
K_{\mathrm{p}}=K_{\mathrm{c}}(R T)^{\Delta n_{\mathrm{gas}}}
$$

17.9 Assuming that ignoring the concentration that reacts introduces no significant error (757):

$$
[\mathrm{A}]_{\text {init }}-[\mathrm{A}]_{\text {reacting }}=[\mathrm{A}]_{\mathrm{eq}} \approx[\mathrm{~A}]_{\text {init }}
$$

17.10 Finding $K$ at one temperature given $K$ at another (van't Hoff equation) (767):

$$
\ln \frac{K_{2}}{K_{1}}=-\frac{\Delta H_{\mathrm{rxn}}^{\circ}}{R}\left(\frac{1}{T_{2}}-\frac{1}{T_{1}}\right)
$$

Highlighted Figures and Tables These figures (F) and tables ( $T$ ) provide a visual review of key ideas.

F17.2 The range of equilibrium constants (740)
F17.3 The change in $Q$ during a reaction (742)
T17.2 Ways of expressing $Q$ and calculating $K$ (747)
F17.5 Reaction direction and the relative sizes of $Q$ and $K$ (750)
F17.6 Steps in solving equilibrium problems (760)

F17.7 Effect of a change in concentration (762)
T17.3 Effect of added $\mathrm{Cl}_{2}$ on the $\mathrm{PCl}_{3}-\mathrm{Cl}_{2}-\mathrm{PCl}_{5}$ system (763)
F17.9 Effect of pressure (volume) on equilibrium (765)
T17.4 Effects of disturbances on equilibrium (768)

Brief Solutions to FOLLOW-UP PROBLEMS Compare your solutions to these calculation steps and answers.
17.1 (a) $Q_{\mathrm{c}}=\frac{[\mathrm{NO}]^{4}\left[\mathrm{H}_{2} \mathrm{O}\right]^{6}}{\left[\mathrm{NH}_{3}\right]^{4}\left[\mathrm{O}_{2}\right]^{5}} \quad$ (b) $Q_{\mathrm{c}}=\frac{\left[\mathrm{N}_{2} \mathrm{O}\right]\left[\mathrm{NO}_{2}\right]}{[\mathrm{NO}]^{3}}$
$17.2 \mathrm{H}_{2}(g)+\mathrm{Br}_{2}(g) \rightleftharpoons 2 \mathrm{HBr}(g)$;
$Q_{c(\text { overall })}=\frac{[\mathrm{HBr}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{Br}_{2}\right]}$
$Q_{\mathrm{c}(\text { overall })}=Q_{\mathrm{c} 1} \times Q_{\mathrm{c} 2} \times Q_{\mathrm{c} 3}$

$$
=\frac{[\mathrm{Br}]^{2}}{\left[\mathrm{Br}_{2}\right]} \times \frac{[\mathrm{HBr}][\mathrm{H}]}{[\mathrm{Br}]\left[\mathrm{H}_{2}\right]} \times \frac{[\mathrm{HBr}]}{[\mathrm{H}][\mathrm{Br}]}=\frac{[\mathrm{HBr}]^{2}}{\left[\mathrm{H}_{2}\right]\left[\mathrm{Br}_{2}\right]}
$$

17.3 (a) $K_{\mathrm{c}}=K_{\mathrm{c}(\text { ref) }}^{1 / 2}=2.8 \times 10^{4}$
(b) $K_{\mathrm{c}}=\left(\frac{1}{K_{\mathrm{c}(\mathrm{ref})}}\right)^{2 / 3}=1.2 \times 10^{-6}$
$17.4 K_{\mathrm{p}}=K_{\mathrm{c}}(R T)^{-1}=1.67\left(0.0821 \frac{\mathrm{~atm} \cdot \mathrm{~L}}{\mathrm{~mol} \cdot \mathrm{~K}} \times 500 . \mathrm{K}\right)^{-1}$

$$
=4.07 \times 10^{-2}
$$

$17.5 K_{\mathrm{c}}=\frac{[\mathrm{Y}]}{[\mathrm{X}]}=1.4$

1. $Q=0.33$, right
2. $Q=1.4$, no change
3. $Q=2.0$, left
$17.6 Q_{\mathrm{p}}=\frac{\left(P_{\mathrm{CH}_{3} \mathrm{Cl}}\right)\left(P_{\mathrm{HCl}}\right)}{\left(P_{\mathrm{CH}_{4}}\right)\left(P_{\mathrm{Cl}_{2}}\right)}=\frac{(0.24)(0.47)}{(0.13)(0.035)}=25$;
$Q_{\mathrm{p}}<K_{\mathrm{p}}$, so $\mathrm{CH}_{3} \mathrm{Cl}$ is forming.
17.7 From the reaction table for $2 \mathrm{NO}+\mathrm{O}_{2} \rightleftharpoons 2 \mathrm{NO}_{2}$,
$P_{\mathrm{O}_{2}}=1.000 \mathrm{~atm}-x=0.506 \mathrm{~atm} \quad x=0.494 \mathrm{~atm}$
Also, $P_{\mathrm{NO}}=0.012 \mathrm{~atm}$ and $P_{\mathrm{NO}_{2}}=0.988 \mathrm{~atm}$, so

$$
K_{\mathrm{p}}=\frac{0.988^{2}}{0.012^{2}(0.506)}=1.3 \times 10^{4}
$$

17.8 Since $\Delta n_{\text {gas }}=0, K_{\mathrm{p}}=K_{\mathrm{c}}=2.3 \times 10^{30}=\frac{(0.781)(0.209)}{P_{\mathrm{NO}}^{2}}$

Thus,

$$
P_{\mathrm{NO}}=2.7 \times 10^{-16} \mathrm{~atm}
$$

17.9 From the reaction table, $\left[\mathrm{H}_{2}\right]=\left[\mathrm{I}_{2}\right]=x ;[\mathrm{HI}]=0.242-2 x$.

Thus,

$$
K_{\mathrm{c}}=1.26 \times 10^{-3}=\frac{x^{2}}{(0.242-2 x)^{2}}
$$

Taking the square root of both sides, ignoring the negative root, and solving gives $x=\left[\mathrm{H}_{2}\right]=8.02 \times 10^{-3} \mathrm{M}$.
17.10 (a) Based on the reaction table, and assuming that $0.20 M-x \approx 0.20 M$,

$$
K_{\mathrm{c}}=2.94 \times 10^{-10} \approx \frac{4 x^{2}}{0.20} \quad x \approx 3.8 \times 10^{-6}
$$

Error $=1.9 \times 10^{-3} \%$, so assumption is justified; therefore, at equilibrium, $\left[\mathrm{I}_{2}\right]=0.20 \mathrm{M}$ and $[\mathrm{I}]=7.6 \times 10^{-6} \mathrm{M}$.
(b) Based on the same reaction table and assumption, $x \approx 0.10$; error is $50 \%$, so assumption is not justified. Solve equation:

$$
4 x^{2}+0.209 x-0.042=0 \quad x=0.080 M
$$

Therefore, at equilibrium, $\left[I_{2}\right]=0.12 M$ and $[I]=0.16 M$.
17.11 (a) $Q_{\mathrm{c}}=\frac{(0.0900)(0.0900)}{0.2100}=3.86 \times 10^{-2}$
$Q_{\mathrm{c}}<K_{\mathrm{c}}$, so reaction proceeds to the right.
(b) From the reaction table,

$$
\left[\mathrm{PCl}_{5}\right]=0.2100 M-x=0.2065 M \quad \text { so } \quad x=0.0035 M
$$

So, $\left[\mathrm{Cl}_{2}\right]=\left[\mathrm{PCl}_{3}\right]=0.0900 M+x=0.0935 \mathrm{M}$.
17.12 (a) $\left[\mathrm{SiF}_{4}\right]$ increases; (b) decreases; (c) decreases; (d) no effect.
17.13 (a) Decrease $P$; (b) increase $P$; (c) increase $P$.
17.14 (a) $P_{\mathrm{H}_{2}}$ will decrease; $K$ will increase; (b) $P_{\mathrm{N}_{2}}$ will increase; $K$ will decrease; (c) $P_{\mathrm{PCl}_{5}}$ will increase; $K$ will increase.
17.15 (a) Since $P=\frac{n}{V} R T$ and, in this case, $V, R$, and $T$ cancel,

$$
K_{\mathrm{p}}=\frac{n_{\mathrm{CD}}^{2}}{n_{\mathrm{C}_{2}} \times n_{\mathrm{D}_{2}}}=\frac{16}{(2)(2)}=4
$$

(b) Scene 2, to the left; scene 3, to the right. (c) There are 2 mol of gas on each side of the balanced equation, so there is no effect on total moles of gas.

## PROBLEMS

Problems with colored numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and provide the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

## The Equilibrium State and the Equilibrium Constant

## - Concept Review Questions

17.1 A change in reaction conditions increases the rate of a certain forward reaction more than that of the reverse reaction. What is the effect on the equilibrium constant and the concentrations of reactants and products at equilibrium?
17.2 When a chemical company employs a new reaction to manufacture a product, the chemists consider its rate (kinetics) and yield (equilibrium). How do each of these affect the usefulness of a manufacturing process?
17.3 If there is no change in concentrations, why is the equilibrium state considered dynamic?
17.4 Is $K$ very large or very small for a reaction that goes essentially to completion? Explain.
17.5 White phosphorus, $\mathrm{P}_{4}$, is produced by the reduction of phosphate rock, $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$. If exposed to oxygen, the waxy, white solid smokes, bursts into flames, and releases a large quantity of heat. Does the reaction

$$
\mathrm{P}_{4}(g)+5 \mathrm{O}_{2}(g) \rightleftharpoons \mathrm{P}_{4} \mathrm{O}_{10}(s)
$$

have a large or small equilibrium constant? Explain.

## The Reaction Quotient and the Equilibrium Constant

 (Sample Problems 17.1 to 17.3).
## - Concept Review Questions

17.6 For a given reaction at a given temperature, the value of $K$ is constant. Is the value of $Q$ also constant? Explain.
17.7 In a study of the thermal decomposition of lithium peroxide,

$$
2 \mathrm{Li}_{2} \mathrm{O}_{2}(s) \rightleftharpoons 2 \mathrm{Li}_{2} \mathrm{O}(s)+\mathrm{O}_{2}(g)
$$

a chemist finds that, as long as some $\mathrm{Li}_{2} \mathrm{O}_{2}$ is present at the end of the experiment, the amount of $\mathrm{O}_{2}$ obtained in a given container at a given $T$ is the same. Explain.
17.8 In a study of the formation of HI from its elements,

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \rightleftharpoons 2 \mathrm{HI}(g)
$$

equal amounts of $\mathrm{H}_{2}$ and $\mathrm{I}_{2}$ were placed in a container, which was then sealed and heated.
(a) On one set of axes, sketch concentration vs. time curves for $\mathrm{H}_{2}$ and HI , and explain how $Q$ changes as a function of time.
(b) Is the value of $Q$ different if $\left[\mathrm{I}_{2}\right]$ is plotted instead of $\left[\mathrm{H}_{2}\right]$ ?
17.9 Explain the difference between a heterogeneous and a homogeneous equilibrium. Give an example of each.
17.10 Does $Q$ for the formation of 1 mol of NO from its elements differ from $Q$ for the decomposition of 1 mol of NO to its elements? Explain and give the relationship between the two $Q$ 's.
17.11 Does $Q$ for the formation of 1 mol of $\mathrm{NH}_{3}$ from $\mathrm{H}_{2}$ and $\mathrm{N}_{2}$ differ from $Q$ for the formation of $\mathrm{NH}_{3}$ from $\mathrm{H}_{2}$ and 1 mol of $\mathrm{N}_{2}$ ? Explain and give the relationship between the two $Q$ 's.

## Skill-Building Exercises (grouped in similar pairs)

17.12 Balance each reaction and write its reaction quotient, $Q_{\mathrm{c}}$ :
(a) $\mathrm{NO}(g)+\mathrm{O}_{2}(g) \rightleftharpoons \mathrm{N}_{2} \mathrm{O}_{3}(g)$
(b) $\mathrm{SF}_{6}(g)+\mathrm{SO}_{3}(g) \rightleftharpoons \mathrm{SO}_{2} \mathrm{~F}_{2}(g)$
(c) $\mathrm{SClF}_{5}(g)+\mathrm{H}_{2}(g) \rightleftharpoons \mathrm{S}_{2} \mathrm{~F}_{10}(g)+\mathrm{HCl}(g)$
17.13 Balance each reaction and write its reaction quotient, $Q_{\mathrm{c}}$ :
(a) $\mathrm{C}_{2} \mathrm{H}_{6}(g)+\mathrm{O}_{2}(g) \rightleftharpoons \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)$
(b) $\mathrm{CH}_{4}(g)+\mathrm{F}_{2}(g) \rightleftharpoons \mathrm{CF}_{4}(g)+\mathrm{HF}(g)$
(c) $\mathrm{SO}_{3}(g) \rightleftharpoons \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g)$
17.14 Balance each reaction and write its reaction quotient, $Q_{\mathrm{c}}$ :
(a) $\mathrm{NO}_{2} \mathrm{Cl}(g) \rightleftharpoons \mathrm{NO}_{2}(g)+\mathrm{Cl}_{2}(g)$
(b) $\mathrm{POCl}_{3}(g) \rightleftharpoons \mathrm{PCl}_{3}(g)+\mathrm{O}_{2}(g)$
(c) $\mathrm{NH}_{3}(g)+\mathrm{O}_{2}(g) \rightleftharpoons \mathrm{N}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)$
17.15 Balance each reaction and write its reaction quotient, $Q_{\mathrm{c}}$ :
(a) $\mathrm{O}_{2}(g) \rightleftharpoons \mathrm{O}_{3}(g)$
(b) $\mathrm{NO}(g)+\mathrm{O}_{3}(g) \rightleftharpoons \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)$
(c) $\mathrm{N}_{2} \mathrm{O}(g)+\mathrm{H}_{2}(g) \rightleftharpoons \mathrm{NH}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(g)$
17.16 At a particular temperature, $K_{\mathrm{c}}=1.6 \times 10^{-2}$ for

$$
2 \mathrm{H}_{2} \mathrm{~S}(g) \rightleftharpoons 2 \mathrm{H}_{2}(g)+\mathrm{S}_{2}(g)
$$

Calculate $K_{\mathrm{c}}$ for each of the following reactions:
(a) $\frac{1}{2} \mathrm{~S}_{2}(g)+\mathrm{H}_{2}(g) \rightleftharpoons \mathrm{H}_{2} \mathrm{~S}(g)$
(b) $5 \mathrm{H}_{2} \mathrm{~S}(g) \rightleftharpoons 5 \mathrm{H}_{2}(g)+\frac{5}{2} \mathrm{~S}_{2}(g)$
17.17 At a particular temperature, $K_{\text {c }}=6.5 \times 10^{2}$ for

$$
2 \mathrm{NO}(g)+2 \mathrm{H}_{2}(g) \rightleftharpoons \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

Calculate $K_{4}$ for each of the following reactions:
คaトツ(g) $+\mathrm{T}_{2}(g) \rightleftharpoons \frac{1}{2} \mathrm{~N}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)$
(b) $2 \mathrm{~N}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons 4 \mathrm{NO}(g)+4 \mathrm{H}_{2}(g)$
17.18 Balance each of the following examples of heterogeneous equilibria and write its reaction quotient, $Q_{\mathrm{c}}$ :
(a) $\mathrm{Na}_{2} \mathrm{O}_{2}(s)+\mathrm{CO}_{2}(g) \rightleftharpoons \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{O}_{2}(g)$
(b) $\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{2} \mathrm{O}(g)$
(c) $\mathrm{NH}_{4} \mathrm{Cl}(s) \rightleftharpoons \mathrm{NH}_{3}(g)+\mathrm{HCl}(g)$
17.19 Balance each of the following examples of heterogeneous equilibria and write its reaction quotient, $Q_{\mathrm{c}}$ :
(a) $\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{SO}_{3}(g) \rightleftharpoons \mathrm{H}_{2} \mathrm{SO}_{4}(a q)$
(b) $\mathrm{KNO}_{3}(s) \rightleftharpoons \mathrm{KNO}_{2}(s)+\mathrm{O}_{2}(g)$
(c) $\mathrm{S}_{8}(s)+\mathrm{F}_{2}(g) \rightleftharpoons \mathrm{SF}_{6}(g)$
17.20 Balance each of the following examples of heterogeneous equilibria and write its reaction quotient, $Q_{\mathrm{c}}$ :
(a) $\mathrm{NaHCO}_{3}(s) \rightleftharpoons \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)$
(b) $\mathrm{SnO}_{2}(s)+\mathrm{H}_{2}(g) \rightleftharpoons \mathrm{Sn}(s)+\mathrm{H}_{2} \mathrm{O}(g)$
(c) $\mathrm{H}_{2} \mathrm{SO} 4(l)+\mathrm{SO}_{3}(g) \rightleftharpoons \mathrm{H}_{2} \mathrm{~S}_{2} \mathrm{O}_{7}(l)$
17.21 Balance each of the following examples of heterogeneous equilibria and write its reaction quotient, $Q_{\mathrm{c}}$ :
(a) $\mathrm{Al}(s)+\mathrm{NaOH}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons$

$$
\mathrm{Na}\left[\mathrm{Al}(\mathrm{OH})_{4}\right](a q)+\mathrm{H}_{2}(\mathrm{~g})
$$

(b) $\mathrm{CO}_{2}(s) \rightleftharpoons \mathrm{CO}_{2}(g)$
(c) $\mathrm{N}_{2} \mathrm{O}_{5}(s) \rightleftharpoons \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)$

## - Problems in Context

17.22 Write $Q_{\mathrm{c}}$ for each of the following:
(a) Hydrogen chloride gas reacts with oxygen gas to produce chlorine gas and water vapor.
(b) Solid diarsenic trioxide reacts with fluorine gas to produce liquid arsenic pentafluoride and oxygen gas.
(c) Gaseous sulfur tetrafluoride reacts with liquid water to produce gaseous sulfur dioxide and hydrogen fluoride gas.
(d) Solid molybdenum(VI) oxide reacts with gaseous xenon difluoride to form liquid molybdenum(VI) fluoride, xenon gas, and oxygen gas.
17.23 The interhalogen $\mathrm{ClF}_{3}$ is prepared in a two-step fluorination of chlorine gas:

$$
\begin{aligned}
\mathrm{Cl}_{2}(g)+\mathrm{F}_{2}(g) & \rightleftharpoons \mathrm{ClF}(g) \\
\mathrm{ClF}(g)+\mathrm{F}_{2}(g) & \rightleftharpoons \mathrm{ClF}_{3}(g)
\end{aligned}
$$

(a) Balance each step and write the overall equation.
(b) Show that the overall $Q_{\mathrm{c}}$ equals the product of the $Q_{\mathrm{c}}$ 's for the individual steps.

## Expressing Equilibria with Pressure Terms: Relation Between $K_{c}$ and $K_{p}$ <br> (Sample Problem 17.4)

## - Concept Review Questions

17.24 Guldberg and Waage proposed the definition of the equilibrium constant as a certain ratio of concentrations. What relationship allows us to use a particular ratio of partial pressures (for a gaseous reaction) to express an equilibrium constant? Explain.
17.25 When are $K_{\mathrm{c}}$ and $K_{\mathrm{p}}$ equal, and when are they not?
17.26 A certain reaction at equilibrium has more moles of gaseous products than of gaseous reactants.
(a) Is $K_{\mathrm{c}}$ larger or smaller than $K_{\mathrm{p}}$ ?
(b) Write a statement about the relative sizes of $K_{\mathrm{c}}$ and $K_{\mathrm{p}}$ for any gaseous equilibrium.

- Skill-Building Exercises (grouped in similar pairs)
17.27 Determine $\Delta n_{\text {gas }}$ for each of the following ractions.
(a) $2 \mathrm{KClO}_{3}(s) \rightleftharpoons 2 \mathrm{KCl}(s)+3 \mathrm{O}_{2}(g)$
(b) $2 \mathrm{PbO}(s)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{PbO}_{2}(s)$
(c) $\mathrm{I}_{2}(s)+3 \mathrm{XeF}_{2}(s) \rightleftharpoons 2 \mathrm{IF}_{3}(s)+3 \mathrm{Xe}(g)$
17.28 Determine $\Delta n_{\text {gas }}$ for each of the following reactions:
(a) $\mathrm{MgCO}_{3}(s) \rightleftharpoons \mathrm{MgO}(s)+\mathrm{CO}_{2}(g)$
(b) $2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{H}_{2} \mathrm{O}(l)$
(c) $\mathrm{HNO}_{3}(l)+\mathrm{ClF}(g) \rightleftharpoons \mathrm{ClONO}_{2}(g)+\mathrm{HF}(g)$
17.29 Calculate $K_{\mathrm{c}}$ for each of the following equilibria:
$(\mathrm{a}) \mathrm{CO}(g)+\mathrm{Cl}_{2}(g) \rightleftharpoons \mathrm{COCl}_{2}(g) ; K_{\mathrm{p}}=3.9 \times 10^{-2}$ at $1000 . \mathrm{K}$
(b) $\mathrm{S}_{2}(g)+\mathrm{C}(s) \rightleftharpoons \mathrm{CS}_{2}(g) ; K_{\mathrm{p}}=28.5$ at $500 . \mathrm{K}$
17.30 Calculate $K_{\mathrm{c}}$ for each of the following equilibria:
(a) $\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \rightleftharpoons 2 \mathrm{HI}(g) ; K_{\mathrm{p}}=49$ at 730 . K
(b) $2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{SO}_{3}(g) ; K_{\mathrm{p}}=2.5 \times 10^{10}$ at 500 . K
17.31 Calculate $K_{\mathrm{p}}$ for each of the following equilibria:
(a) $\mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftharpoons 2 \mathrm{NO}_{2}(g) ; K_{\mathrm{c}}=6.1 \times 10^{-3}$ at 298 K
(b) $\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g) ; K_{\mathrm{c}}=2.4 \times 10^{-3}$ at 1000 . K
17.32 Calculate $K_{\mathrm{p}}$ for each of the following equilibria:
(a) $\mathrm{H}_{2}(g)+\mathrm{CO}_{2}(g) \rightleftharpoons \mathrm{H}_{2} \mathrm{O}(g)+\mathrm{CO}(g) ; K_{\mathrm{c}}=0.77$ at $1020 . \mathrm{K}$
(b) $3 \mathrm{O}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{O}_{3}(\mathrm{~g}) ; K_{\mathrm{c}}=1.8 \times 10^{-56}$ at $570 . \mathrm{K}$

## Reaction Direction: Comparing $Q$ and $K$ <br> (Sample Problems 17.5 and 17.6)

## - Concept Review Questions

17.33 When the numerical value of $Q$ is less than $K$, in which direction does the reaction proceed to reach equilibrium? Explain.
17.34 The following molecular scenes depict the aqueous reaction $2 \mathrm{D} \rightleftharpoons \mathrm{E}$, with D red and E blue. Each sphere represents 0.0100 mol , but the volume in scene A is 1.00 L , whereas in scenes B and C, it is 0.500 L .

(a) If the reaction in scene A is at equilibrium, calculate $K_{\mathrm{c}}$.
(b) Are the reactions in scenes B and C at equilibrium? Which, if either, is not, and in which direction will it proceed?

## - Skill-Building Exercises (grouped in similar pairs)

17.35 At $425^{\circ} \mathrm{C}, K_{\mathrm{p}}=4.18 \times 10^{-9}$ for the reaction

$$
2 \mathrm{HBr}(g) \rightleftharpoons \mathrm{H}_{2}(g)+\mathrm{Br}_{2}(g)
$$

In one experiment, 0.20 atm of $\operatorname{HBr}(g), 0.010 \mathrm{~atm}$ of $\mathrm{H}_{2}(g)$, and 0.010 atm of $\mathrm{Br}_{2}(\mathrm{~g})$ are introduced into a container. Is the reaction at equilibrium? If not, in which direction will it proceed?
17.36 At $100^{\circ} \mathrm{C}, K_{\mathrm{p}}=60.6$ for the reaction

$$
2 \mathrm{NOBr}(g) \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{Br}_{2}(g)
$$

In a given experiment, 0.10 atm of each component is placed in a container. Is the system at equilibrium? If not, in which direction will the reaction proceed?

## - Problems in Context

17.37 The water-gas shift reaction plays a central role in the chemical methods for obtaining cleaner fuels from coal:

$$
\mathrm{CO}(g)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons \mathrm{CO}_{2}(g)+\mathrm{H}_{2}(g)
$$

At a given temperature, $K_{\mathrm{p}}=2.7$. If 0.13 mol of $\mathrm{CO}, 0.56 \mathrm{~mol}$ of $\mathrm{H}_{2}-1,9.62 \mathrm{~m}-\mathrm{Af} \mathrm{CO}_{2}$, and 0.43 mol of $\mathrm{H}_{2}$ are put in a $2.0-\mathrm{L}$ flask, in which direction does the reaction proceed?

## How to Solve Equilibrium Problems

(Sample Problems 17.7 to 17.11)

## - Concept Review Questions

17.38 In the 1980s, CFC-11 was one of the most heavily produced chlorofluorocarbons. The last step in its formation is

$$
\mathrm{CCl}_{4}(g)+\mathrm{HF}(g) \rightleftharpoons \mathrm{CFCl}_{3}(g)+\mathrm{HCl}(g)
$$

If you start the reaction with equal concentrations of $\mathrm{CCl}_{4}$ and HF , you obtain equal concentrations of $\mathrm{CFCl}_{3}$ and HCl at equilibrium. Are the final concentrations of $\mathrm{CFCl}_{3}$ and HCl equal if you start with unequal concentrations of $\mathrm{CCl}_{4}$ and HF? Explain. 17.39 For a problem involving the catalyzed reaction of methane and steam, the following reaction table was prepared:

| Pressure <br> (atm) | $\mathbf{C H}_{\mathbf{4}}(\boldsymbol{g})+$ | $\mathbf{2} \mathbf{H}_{\mathbf{2}} \mathbf{O}(\boldsymbol{g}) \rightleftharpoons$ | $\mathbf{C O}_{\mathbf{2}}(\boldsymbol{g})+\mathbf{4 \mathbf { H } _ { \mathbf { 2 } }} \mathbf{( g )}$ |  |
| :--- | :---: | :---: | :---: | :---: |
| Initial | 0.30 | 0.40 | 0 | 0 |
| Change | $-x$ | $-2 x$ | $+x$ | $+4 x$ |
| Equilibrium | $0.30-x$ | $0.40-2 x$ | $x$ | $4 x$ |

Explain the entries in the "Change" and "Equilibrium" rows. 17.40 (a) What is the basis of the approximation that avoids using the quadratic formula to find an equilibrium concentration?
(b) When should this approximation not be made?

Skill-Building Exercises (grouped in similar pairs) 17.41 In an experiment to study the formation of $\mathrm{HI}(g)$,

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(g) \rightleftharpoons 2 \mathrm{HI}(g)
$$

$\mathrm{H}_{2}(g)$ and $\mathrm{I}_{2}(g)$ were placed in a sealed container at a certain temperature. At equilibrium, $\left[\mathrm{H}_{2}\right]=6.50 \times 10^{-5} \mathrm{M},\left[\mathrm{I}_{2}\right]=$ $1.06 \times 10^{-3} M$, and $[\mathrm{HI}]=1.87 \times 10^{-3} M$. Calculate $K_{\mathrm{c}}$ for the reaction at this temperature.
17.42 Gaseous ammonia was introduced into a sealed container and heated to a certain temperature:

$$
2 \mathrm{NH}_{3}(g) \rightleftharpoons \mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g)
$$

At equilibrium, $\left[\mathrm{NH}_{3}\right]=0.0225 \mathrm{M},\left[\mathrm{N}_{2}\right]=0.114 \mathrm{M}$, and $\left[\mathrm{H}_{2}\right]=$ 0.342 M . Calculate $K_{\mathrm{c}}$ for the reaction at this temperature.
17.43 Gaseous $\mathrm{PCl}_{5}$ decomposes according to the reaction

$$
\mathrm{PCl}_{5}(g) \rightleftharpoons \mathrm{PCl}_{3}(g)+\mathrm{Cl}_{2}(g)
$$

In one experiment, 0.15 mol of $\mathrm{PCl}_{5}(\mathrm{~g})$ was introduced into a $2.0-\mathrm{L}$ container. Construct the reaction table for this process.
17.44 Hydrogen fluoride, HF , can be made from the reaction

$$
\mathrm{H}_{2}(g)+\mathrm{F}_{2}(g) \rightleftharpoons 2 \mathrm{HF}(g)
$$

In one experiment, 0.10 mol of $\mathrm{H}_{2}(g)$ and 0.050 mol of $\mathrm{F}_{2}(g)$ are added to a 0.50 -L flask. Write a reaction table for this process.
17.45 For the following reaction, $K_{\mathrm{p}}=6.5 \times 10^{4}$ at 308 K :

$$
2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g) \rightleftharpoons 2 \mathrm{NOCl}(g)
$$

At equilibrium, $P_{\mathrm{NO}}=0.35 \mathrm{~atm}$ and $P_{\mathrm{Cl}_{2}}=0.10 \mathrm{~atm}$. What is the equilibrium partial pressure of $\mathrm{NOCl}(\mathrm{g})$ ?
17.46 For the following reaction, $K_{\mathrm{p}}=0.262$ at $1000^{\circ} \mathrm{C}$ :

$$
\mathrm{C}(s)+2 \mathrm{H}_{2}(g) \rightleftharpoons \mathrm{CH}_{4}(g)
$$

At equilibrium, $P_{\mathrm{H}_{2}}$ is 1.22 atm . What is the equilibrium partial pressure of $\mathrm{CH}_{4}(\mathrm{~g})$ ?
17.47 Ammonium hydrogen sulfide decomposes according to the following reaction, for which $K_{\mathrm{p}}=0.11$ at $250^{\circ} \mathrm{C}$; PDE

$$
\left.\mathrm{NH}_{4} \mathrm{HS}(s) \rightleftharpoons \mathrm{H}_{2} \mathrm{~S}(g)-2 \mathrm{NH}_{3}{ }^{( }\right)
$$

If 55.0 g of $\mathrm{NH}_{4} \mathrm{HS}(s)$ is placed in a sealed 5.0-L container, what is the partial pressure of $\mathrm{NH}_{3}(g)$ at equilibrium?
17.48 Hydrogen sulfide decomposes according to the following reaction, for which $K_{\mathrm{c}}=9.30 \times 10^{-8}$ at $700^{\circ} \mathrm{C}$ :

$$
2 \mathrm{H}_{2} \mathrm{~S}(g) \rightleftharpoons 2 \mathrm{H}_{2}(g)+\mathrm{S}_{2}(g)
$$

If 0.45 mol of $\mathrm{H}_{2} \mathrm{~S}$ is placed in a 3.0-L container, what is the equilibrium concentration of $\mathrm{H}_{2}(\mathrm{~g})$ at $700^{\circ} \mathrm{C}$ ?
17.49 Even at high $T$, the formation of NO is not favored:
$\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}(g) \quad K_{\mathrm{c}}=4.10 \times 10^{-4}$ at $2000^{\circ} \mathrm{C}$
What is [NO] when a mixture of 0.20 mol of $\mathrm{N}_{2}(\mathrm{~g})$ and 0.15 mol of $\mathrm{O}_{2}(\mathrm{~g})$ reach equilibrium in a $1.0-\mathrm{L}$ container at $2000^{\circ} \mathrm{C}$ ?
17.50 Nitrogen dioxide decomposes according to the reaction

$$
2 \mathrm{NO}_{2}(g) \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)
$$

where $K_{\mathrm{p}}=4.48 \times 10^{-13}$ at a certain temperature. If 0.75 atm of $\mathrm{NO}_{2}$ is added to a container and allowed to come to equilibrium, what are the equilibrium partial pressures of $\mathrm{NO}(g)$ and $\mathrm{O}_{2}(g)$ ?
17.51 Hydrogen iodide decomposes according to the reaction

$$
2 \mathrm{HI}(g) \rightleftharpoons \mathrm{H}_{2}(g)+\mathrm{I}_{2}(g)
$$

A sealed 1.50-L container initially holds 0.00623 mol of $\mathrm{H}_{2}$, 0.00414 mol of $\mathrm{I}_{2}$, and 0.0244 mol of HI at 703 K . When equilibrium is reached, the concentration of $\mathrm{H}_{2}(g)$ is 0.00467 M . What are the concentrations of $\mathrm{HI}(g)$ and $\mathrm{I}_{2}(g)$ ?
17.52 Compound A decomposes according to the equation

$$
\mathrm{A}(g) \rightleftharpoons 2 \mathrm{~B}(g)+\mathrm{C}(g)
$$

A sealed 1.00 -L container initially contains $1.75 \times 10^{-3} \mathrm{~mol}$ of $\mathrm{A}(g), 1.25 \times 10^{-3} \mathrm{~mol}$ of $\mathrm{B}(\mathrm{g})$, and $6.50 \times 10^{-4} \mathrm{~mol}$ of $\mathrm{C}(g)$ at $100^{\circ} \mathrm{C}$. At equilibrium, $[\mathrm{A}]$ is $2.15 \times 10^{-3} \mathrm{M}$. Find [B] and [C].

## Problems in Context

17.53 In an analysis of interhalogen reactivity, 0.500 mol of ICl was placed in a $5.00-\mathrm{L}$ flask, where it decomposed at a high $T$ : $2 \mathrm{ICl}(g) \rightleftharpoons \mathrm{I}_{2}(g)+\mathrm{Cl}_{2}(g)$. Calculate the equilibrium concentrations of $\mathrm{I}_{2}, \mathrm{Cl}_{2}$, and ICl ( $K_{\mathrm{c}}=0.110$ at this temperature).
17.54 A toxicologist studying mustard gas, $\mathrm{S}\left(\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{Cl}\right)_{2}$, a blistering agent, prepares a mixture of $0.675 \mathrm{M} \mathrm{SCl}_{2}$ and 0.973 M $\mathrm{C}_{2} \mathrm{H}_{4}$ and allows it to react at room temperature $\left(20.0^{\circ} \mathrm{C}\right)$ :

$$
\mathrm{SCl}_{2}(g)+2 \mathrm{C}_{2} \mathrm{H}_{4}(g) \rightleftharpoons \mathrm{S}\left(\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{Cl}\right)_{2}(g)
$$

17.55 The first step in $\mathrm{HNO}_{3}$ production is the catalyzed oxidation of $\mathrm{NH}_{3}$. Without a catalyst, a different reaction predominates:

$$
4 \mathrm{NH}_{3}(g)+3 \mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{~N}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)
$$

When 0.0150 mol of $\mathrm{NH}_{3}(g)$ and 0.0150 mol of $\mathrm{O}_{2}(\mathrm{~g})$ are placed in a $1.00-\mathrm{L}$ container at a certain temperature, the $\mathrm{N}_{2}$ concentration at equilibrium is $1.96 \times 10^{-3} \mathrm{M}$. Calculate $K_{\mathrm{c}}$.
17.56 A key step in the extraction of iron from its ore is
$\mathrm{FeO}(s)+\mathrm{CO}(g) \rightleftharpoons \mathrm{Fe}(s)+\mathrm{CO}_{2}(g) \quad K_{\mathrm{p}}=0.403$ at $1000^{\circ} \mathrm{C}$
This step occurs in the $700^{\circ} \mathrm{C}$ to $1200^{\circ} \mathrm{C}$ zone within a blast furnace. What are the equilibrium partial pressures of $\mathrm{CO}(g)$ and $\mathrm{CO}_{2}(g)$ when 1.00 atm of $\mathrm{CO}(g)$ and excess $\mathrm{FeO}(s)$ react in a sealed container at $1000^{\circ} \mathrm{C}$ ?

## Reaction Conditions and the Equilibrium State: Le Châtelier's Principle

(Sample Problems 17.12 to 17.15)

## - Concept Review Questions

17.57 What does "disturbance" mean in Le Châtelier's principle?

Fis. 18 What is! the difference between the equilibrium position and the equilibrium constant of a reaction? Which changes as a result of a change in reactant concentration?
17.59 Scenes A, B, and C below depict this reaction at three temperatures:

(a) Which best represents the reaction mixture at the highest temperature? Explain. (b) Which best represents the reaction mixture at the lowest temperature? Explain.
17.60 What is implied by the word "constant" in the term equilibrium constant? Give two reaction parameters that can be changed without changing the value of an equilibrium constant.
17.61 Le Châtelier's principle is related ultimately to the rates of the forward and reverse steps in a reaction. Explain (a) why an increase in reactant concentration shifts the equilibrium position to the right but does not change $K$; (b) why a decrease in $V$ shifts the equilibrium position toward fewer moles of gas but does not change $K$; (c) why a rise in $T$ shifts the equilibrium position of an exothermic reaction toward reactants and also changes $K$; and (d) why a rise in temperature of an endothermic reaction from $T_{1}$ to $T_{2}$ results in $K_{2}$ being larger than $K_{1}$.
17.62 An equilibrium mixture of two solids and a gas, in the reaction $\mathrm{XY}(s) \rightleftharpoons \mathrm{X}(g)+\mathrm{Y}(s)$, is depicted at right ( X is green and Y is black). Does scene A, B, or C best represent the system at equilibrium after two formula units of $\mathrm{Y}(s)$ is added? Explain.

## Skill-Building Exercises (grouped in similar pairs)

17.63 Consider this equilibrium system:

$$
\mathrm{CO}(g)+\mathrm{Fe}_{3} \mathrm{O}_{4}(s) \rightleftharpoons \mathrm{CO}_{2}(g)+3 \mathrm{FeO}(s)
$$

How does the equilibrium position shift as a result of each of the following disturbances? (a) CO is added. (b) $\mathrm{CO}_{2}$ is removed by adding solid NaOH . (c) Additional $\mathrm{Fe}_{3} \mathrm{O}_{4}(s)$ is added to the system. (d) Dry ice is added at constant temperature.
17.64 Sodium bicarbonate undergoes thermal decomposition according to the reaction

$$
2 \mathrm{NaHCO}_{3}(s) \rightleftharpoons \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)
$$

How does the equilibrium position shift as a result of each of the following disturbances? (a) 0.20 atm of argon gas is added. (b) $\mathrm{NaHCO}_{3}(s)$ is added. (c) $\mathrm{Mg}\left(\mathrm{ClO}_{4}\right)_{2}(s)$ is added as a drying agent to remove $\mathrm{H}_{2} \mathrm{O}$. (d) Dry ice is added ateonstanto PDE
17.65 Predict the effect of increasing the container volume on the amounts of each reactant and product in the following reactions:
(a) $\mathrm{F}_{2}(g) \rightleftharpoons 2 \mathrm{~F}(g)$
(b) $2 \mathrm{CH}_{4}(g) \rightleftharpoons \mathrm{C}_{2} \mathrm{H}_{2}(g)+3 \mathrm{H}_{2}(g)$
17.66 Predict the effect of increasing the container volume on the amounts of each reactant and product in the following reactions:
(a) $\mathrm{CH}_{3} \mathrm{OH}(l) \rightleftharpoons \mathrm{CH}_{3} \mathrm{OH}(g)$
(b) $\mathrm{CH}_{4}(g)+\mathrm{NH}_{3}(g) \rightleftharpoons \mathrm{HCN}(g)+3 \mathrm{H}_{2}(g)$
17.67 Predict the effect of decreasing the container volume on the amounts of each reactant and product in the following reactions:
(a) $\mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g) \rightleftharpoons 2 \mathrm{HCl}(g)$
(b) $2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{H}_{2} \mathrm{O}(l)$
17.68 Predict the effect of decreasing the container volume on the amounts of each reactant and product in the following reactions:
(a) $\mathrm{C}_{3} \mathrm{H}_{8}(g)+5 \mathrm{O}_{2}(g) \rightleftharpoons 3 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(l)$
(b) $4 \mathrm{NH}_{3}(g)+3 \mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{~N}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)$
17.69 How would you adjust the volume of the container in order to maximize product yield in each of the following reactions?
(a) $\mathrm{Fe}_{3} \mathrm{O}_{4}(s)+4 \mathrm{H}_{2}(g) \rightleftharpoons 3 \mathrm{Fe}(s)+4 \mathrm{H}_{2} \mathrm{O}(g)$
(b) $2 \mathrm{C}(s)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{CO}(g)$
17.70 How would you adjust the volume of the container in order to maximize product yield in each of the following reactions?
(a) $\mathrm{Na}_{2} \mathrm{O}_{2}(s) \rightleftharpoons 2 \mathrm{Na}(l)+\mathrm{O}_{2}(g)$
(b) $\mathrm{C}_{2} \mathrm{H}_{2}(g)+2 \mathrm{H}_{2}(g) \rightleftharpoons \mathrm{C}_{2} \mathrm{H}_{6}(g)$
17.71 Predict the effect of increasing the temperature on the amounts of products in the following reactions:
(a) $\mathrm{CO}(g)+2 \mathrm{H}_{2}(g) \rightleftharpoons \mathrm{CH}_{3} \mathrm{OH}(g)$
$\Delta H_{\mathrm{rxn}}^{\circ}=-90.7 \mathrm{~kJ}$
(b) $\mathrm{C}(s)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons \mathrm{CO}(g)+\mathrm{H}_{2}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=131 \mathrm{~kJ}$
(c) $2 \mathrm{NO}_{2}(g) \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{O}_{2}(g)$ (endothermic)
(d) $2 \mathrm{C}(s)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{CO}(g)$ (exothermic)
17.72 Predict the effect of decreasing the temperature on the amounts of reactants in the following reactions:
(a) $\mathrm{C}_{2} \mathrm{H}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons \mathrm{CH}_{3} \mathrm{CHO}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-151 \mathrm{~kJ}$
(b) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}(l)+\mathrm{O}_{2}(g) \rightleftharpoons \mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}(l)+\mathrm{H}_{2} \mathrm{O}(g)$
$\left.\Delta H_{\mathrm{rxn}}^{\circ}=-451 \mathrm{~kJ}\right]$
(c) $2 \mathrm{C}_{2} \mathrm{H}_{4}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{CH}_{3} \mathrm{CHO}(g)$ (exothermic)
$(d) \mathrm{N}_{2} \mathrm{O}_{4}(g) \rightleftharpoons 2 \mathrm{NO}_{2}(g)$ (endothermic)
17.73 The molecule $\mathrm{D}_{2}$ (where D , deuterium, is ${ }^{2} \mathrm{H}$ ) undergoes a reaction with ordinary $\mathrm{H}_{2}$ that leads to isotopic equilibrium:

$$
\mathrm{D}_{2}(g)+\mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{DH}(g) \quad K_{\mathrm{p}}=1.80 \text { at } 298 \mathrm{~K}
$$

If $\Delta H_{\mathrm{rxn}}^{\circ}$ is $0.32 \mathrm{~kJ} / \mathrm{mol} \mathrm{DH}$, calculate $K_{\mathrm{p}}$ at $500 . \mathrm{K}$.
17.74 The formation of methanol is important to the processing of new fuels. At $298 \mathrm{~K}, K_{\mathrm{p}}=2.25 \times 10^{4}$ for the reaction

$$
\mathrm{CO}(g)+2 \mathrm{H}_{2}(g) \rightleftharpoons \mathrm{CH}_{3} \mathrm{OH}(l)
$$

If $\Delta H_{\mathrm{rxn}}^{\circ}=-128 \mathrm{~kJ} / \mathrm{mol} \mathrm{CH}_{3} \mathrm{OH}$, calculate $K_{\mathrm{p}}$ at $0^{\circ} \mathrm{C}$.

## Problems in Context

17.75 The minerals hematite $\left(\mathrm{Fe}_{2} \mathrm{O}_{3}\right)$ and magnetite $\left(\mathrm{Fe}_{3} \mathrm{O}_{4}\right)$ exist in equilibrium with atmospheric oxygen:
$4 \mathrm{Fe}_{3} \mathrm{O}_{4}(s)+\mathrm{O}_{2}(g) \rightleftharpoons 6 \mathrm{Fe}_{2} \mathrm{O}_{3}(s) \quad K_{\mathrm{p}}=2.5 \times 10^{87}$ at 298 K
(a) Determine $P_{\mathrm{O}_{2}}$ at equilibrium. (b) Given that $P_{\mathrm{O}_{2}}$ in air is 0.21 atm , in which direction will the reaction proceed to reach equilibrium? (c) Calculate $K_{\mathrm{c}}$ at 298 K .
17.76 The oxidation of $\mathrm{SO}_{2}$ is the key step in $\mathrm{H}_{2} \mathrm{SO}_{4}$ production:

$$
\mathrm{SO}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \rightleftharpoons \mathrm{SO}_{3}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-99.2 \mathrm{~kJ}
$$

(a) What qualitative combination of $T$ and $P$ maximizes $\mathrm{SO}_{3}$ yield?
(b) Howldoes addition-of $\mathrm{O}_{2}$ affect $Q$ ? $K$ ?
(c) Why is catalysis used for this reaction?

## Comprehensive Problems

17.77 The "filmstrip" represents five molecular scenes of a gaseous mixture as it reaches equilibrium over time:

X is purple and Y is orange: $\mathrm{X}_{2}(g)+\mathrm{Y}_{2}(g) \rightleftharpoons 2 \mathrm{XY}(g)$.
(a) Write the reaction quotient, $Q$, for this reaction.
(b) If each particle represents 0.1 mol , find $Q$ for each scene.
(c) If $K>1$, is time progressing to the right or to the left? Explain.
(d) Calculate $K$ at this temperature.
(e) If $\Delta H_{\mathrm{rxn}}^{\circ}<0$, which scene, if any, best represents the mixture at a higher temperature? Explain.
(f) Which scene, if any, best represents the mixture at a higher pressure (lower volume)? Explain.
17.78 The powerful chlorinating agent sulfuryl dichloride $\left(\mathrm{SO}_{2} \mathrm{Cl}_{2}\right)$ can be prepared by the following two-step sequence:

$$
\begin{aligned}
& \mathrm{H}_{2} \mathrm{~S}(g)+\mathrm{O}_{2}(g) \rightleftharpoons \mathrm{SO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g) \\
& \mathrm{SO}_{2}(g)+\mathrm{Cl}_{2}(g) \rightleftharpoons \mathrm{SO}_{2} \mathrm{Cl}_{2}(g)
\end{aligned}
$$

(a) Balance each step, and write the overall equation.
(b) Show that the overall $Q_{\mathrm{c}}$ equals the product of the $Q_{\mathrm{c}}$ 's for the individual steps.
17.79 A mixture of 5.00 volumes of $\mathrm{N}_{2}$ and 1.00 volume of $\mathrm{O}_{2}$ passes slowly through a heated furnace. Assuming it reaches equilibrium at 1850 K and 5.00 atm , the reaction is

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}(g) \quad K_{\mathrm{p}}=1.47 \times 10^{-4}
$$

(a) What is the partial pressure of NO? (b) What is the concentration in micrograms per liter ( $\mu \mathrm{g} / \mathrm{L}$ ) of NO in the mixture?
17.80 For the following equilibrium system, which of the changes will form more $\mathrm{CaCO}_{3}$ ?

$$
\begin{array}{r}
\mathrm{CO}_{2}(g)+\mathrm{Ca}(\mathrm{OH})_{2}(s) \rightleftharpoons \mathrm{CaCO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l) \\
\Delta H^{\circ}=-113 \mathrm{~kJ}
\end{array}
$$

(a) Decrease temperature at constant pressure (no phase change)
(b) Increase volume at constant temperature
(c) Increase partial pressure of $\mathrm{CO}_{2}$
(d) Remove one-half of the initial $\mathrm{CaCO}_{3}$
17.81 Ammonium carbamate $\left(\mathrm{NH}_{2} \mathrm{COONH}_{4}\right)$ is a salt of carbamic acid that is found in the blood and urine of mammals. At $250 .{ }^{\circ} \mathrm{C}$, $K_{\text {c }}=1.58 \times 10^{-8}$ for the following equilibrium:

$$
\mathrm{NH}_{2} \mathrm{COONH}_{4}(s) \rightleftharpoons 2 \mathrm{NH}_{3}(g)+\mathrm{CO}_{2}(g)
$$

If 7.80 g of $\mathrm{NH}_{2} \mathrm{COONH}_{4}$ is put into a $0.500-\mathrm{L}$ evacuated container, what is the total pressure at equilibrium?
17.82 Isolation of Group $8 \mathrm{~B}(10)$ elements, used as industrial catalysts, involves a series of steps. For nickel, the sulfide ore is roasted in air: $\mathrm{Ni}_{3} \mathrm{~S}_{2}(s)+\mathrm{O}_{2}(g) \rightleftharpoons \mathrm{NiO}(s)+\mathrm{SO}_{2}(g)$. The metal oxide is reduced by the $\mathrm{H}_{2}$ in water gas $\left(\mathrm{CO}+\mathrm{H}_{2}\right)$ to impure $\mathrm{Ni}: \mathrm{NiO}(s)+\mathrm{H}_{2}(g) \rightleftharpoons \mathrm{Ni}(s)+\mathrm{H}_{2} \mathrm{O}(g)$. The CO in water gas then reacts with the metal in the Mond process to form gaseous nickel carbonyl, $\mathrm{Ni}(s)+\mathrm{GO}(g) \underset{\square}{\Longrightarrow} \mathrm{Ni}(\mathrm{CO})_{4}\left(\mathrm{~g}_{\mathrm{g}}\right)$, which is subsequently decomposed to the metal. (a) Batance each of the three steps, and obtain an overall balanced equation for the conversion of $\mathrm{Ni}_{3} \mathrm{~S}_{2}$ to $\mathrm{Ni}(\mathrm{CO})_{4}$. (b) Show that the overall $Q_{\mathrm{c}}$ is the product of the $Q_{\mathrm{c}}$ 's for the individual reactions.
17.83 Consider the formation of ammonia in two experiments.
(a) To a $1.00-\mathrm{L}$ container at $727^{\circ} \mathrm{C}, 1.30 \mathrm{~mol}$ of $\mathrm{N}_{2}$ and 1.65 mol of $\mathrm{H}_{2}$ are added. At equilibrium, 0.100 mol of $\mathrm{NH}_{3}$ is present. Calculate the equilibrium concentrations of $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$, and find $K_{\mathrm{c}}$ for the reaction: $2 \mathrm{NH}_{3}(g) \rightleftharpoons \mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g)$.
(b) In a different $1.00-\mathrm{L}$ container at the same temperature, equilibrium is established with $8.34 \times 10^{-2} \mathrm{~mol}$ of $\mathrm{NH}_{3}, 1.50 \mathrm{~mol}$ of $\mathrm{N}_{2}$, and 1.25 mol of $\mathrm{H}_{2}$ present. Calculate $K_{\mathrm{c}}$ for the reaction:

$$
\mathrm{NH}_{3}(g) \rightleftharpoons \frac{1}{2} \mathrm{~N}_{2}(g)+\frac{3}{2} \mathrm{H}_{2}(g)
$$

(c) What is the relationship between the $K_{\mathrm{c}}$ values in parts (a) and (b)? Why aren't these values the same?
17.84 An important industrial source of ethanol is the reaction, catalyzed by $\mathrm{H}_{3} \mathrm{PO}_{4}$, of steam with ethylene derived from oil:

$$
\begin{gathered}
\mathrm{C}_{2} \mathrm{H}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(g) \underset{K_{\mathrm{c}}=9 \times 10^{3} \text { at } 600 . \mathrm{K}}{\Delta H_{\mathrm{rxn}}^{\circ}=-47.8 \mathrm{~kJ}} \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(g) \\
{ }^{\circ}=-4
\end{gathered}
$$

(a) At equilibrium, $P_{\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}}=200$. atm and $P_{\mathrm{H}_{2} \mathrm{O}}=400$. atm. Calculate $P_{\mathrm{C}_{2} \mathrm{H}_{4}}$. (b) Is the highest yield of ethanol obtained at high or low $P$ ? High or low $T$ ? (c) Calculate $K_{\mathrm{c}}$ at 450 . K. (d) In $\mathrm{NH}_{3}$ manufacture, the yield is increased by condensing the $\mathrm{NH}_{3}$ to a liquid and removing it. Would condensing the $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ have the same effect in ethanol production? Explain.
17.85 Which of the following situations represent equilibrium?
(a) Migratory birds fly north in summer and south in winter.
(b) In a grocery store, some carts are kept inside and some outside. Customers bring carts out to their cars, while store clerks bring carts in to replace those taken out.
(c) In a tug o' war, a ribbon tied to the center of the rope moves back and forth until one side loses, after which the ribbon goes all the way to the winner's side.
(d) As a stew is cooking, water in the stew vaporizes, and the vapor condenses on the lid to droplets that drip into the stew.
17.86 An industrial chemist introduces 2.0 atm of $\mathrm{H}_{2}$ and 2.0 atm of $\mathrm{CO}_{2}$ into a $1.00-\mathrm{L}$ container at $25.0^{\circ} \mathrm{C}$ and then raises the temperature to $700 .{ }^{\circ} \mathrm{C}$, at which $K_{\mathrm{c}}=0.534$ :

$$
\mathrm{H}_{2}(g)+\mathrm{CO}_{2}(g) \rightleftharpoons \mathrm{H}_{2} \mathrm{O}(g)+\mathrm{CO}(g)
$$

How many grams of $\mathrm{H}_{2}$ are present at equilibrium?
17.87 As an EPA scientist studying catalytic converters and urban smog, you want to find $K_{\mathrm{c}}$ for the following reaction:

$$
2 \mathrm{NO}_{2}(g) \rightleftharpoons \mathrm{N}_{2}(g)+2 \mathrm{O}_{2}(g) \quad K_{\mathrm{c}}=?
$$

Use the following data to find the unknown $K_{\mathrm{c}}$ :

$$
\begin{aligned}
\frac{1}{2} \mathrm{~N}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) & \rightleftharpoons \mathrm{NO}(g) \\
2 \mathrm{NO}_{2}(g) \rightleftharpoons & K_{\mathrm{c}}=4.8 \times 10^{-10} \\
& \mathrm{NO}(g)+\mathrm{O}_{2}(g) \\
K_{\mathrm{c}} & =1.1 \times 10^{-5}
\end{aligned}
$$

17.88 An inorganic chemist places 1 mol of BrCl in container A and 0.5 mol of $\mathrm{Br}_{2}$ and 0.5 mol of $\mathrm{Cl}_{2}$ in container B. She seals the containers and heats them to $300^{\circ} \mathrm{C}$. With time, both containers hold identical mixtures of $\mathrm{BrCl}, \mathrm{Br}_{2}$, and $\mathrm{Cl}_{2}$.
(a) Write a balanced equation for the reaction in container A .
(b) Write the reaction quotient, $Q$, for this reaction.
(c) How do the values of $Q$ in A and in B compare over time?
(d) Explain on the molecular level how it is possible for both containers to end up with identical mixtures.
17.89 An engineer examining the oxidation of $\mathrm{SO}_{2}$ in the manufacture of sulfuric acid determines that $K_{\mathrm{c}}=1.7 \times 10^{8}$ at 600 . K:
Enhance ${ }^{2 \mathrm{SO}_{2}}(\mathrm{~g})+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{SO}_{3}(\mathrm{~g})$
(a) At equilibrium, $P_{\mathrm{SO}_{3}}=300$. atm and $P_{\mathrm{O}_{2}}=100$. atm. Calculate $P_{\mathrm{SO}_{2}}$. (b) The engineer places a mixture of 0.0040 mol of $\mathrm{SO}_{2}(g)$ and 0.0028 mol of $\mathrm{O}_{2}(g)$ in a 1.0-L container and raises the temperature to 1000 K . At equilibrium, 0.0020 mol of $\mathrm{SO}_{3}(\mathrm{~g})$ is present. Calculate $K_{\mathrm{c}}$ and $P_{\mathrm{SO}_{2}}$ for this reaction at 1000 . K.
17.90 Phosgene $\left(\mathrm{COCl}_{2}\right)$ is a toxic substance that forms readily from carbon monoxide and chlorine at elevated temperatures:

$$
\mathrm{CO}(g)+\mathrm{Cl}_{2}(g) \rightleftharpoons \mathrm{COCl}_{2}(g)
$$

If 0.350 mol of each reactant is placed in a $0.500-\mathrm{L}$ flask at 600 K , what are the concentrations of all three substances at equilibrium ( $K_{\mathrm{c}}=4.95$ at this temperature)?
17.91 When 0.100 mol of $\mathrm{CaCO}_{3}(s)$ and 0.100 mol of $\mathrm{CaO}(s)$ are placed in an evacuated sealed $10.0-\mathrm{L}$ container and heated to $385 \mathrm{~K}, P_{\mathrm{CO}_{2}}=0.220 \mathrm{~atm}$ after equilibrium is established:

$$
\mathrm{CaCO}_{3}(s) \rightleftharpoons \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

An additional 0.300 atm of $\mathrm{CO}_{2}(\mathrm{~g})$ is pumped in. What is the total mass (in g ) of $\mathrm{CaCO}_{3}$ after equilibrium is re-established?
17.92 Use each of the following reaction quotients to write the balanced equation:
(a) $Q=\frac{\left[\mathrm{CO}_{2}\right]^{2}\left[\mathrm{H}_{2} \mathrm{O}\right]^{2}}{\left[\mathrm{C}_{2} \mathrm{H}_{4}\right]\left[\mathrm{O}_{2}\right]^{3}}$
(b) $Q=\frac{\left[\mathrm{NH}_{3}\right]^{4}\left[\mathrm{O}_{2}\right]^{7}}{\left[\mathrm{NO}_{2}\right]^{4}\left[\mathrm{H}_{2} \mathrm{O}\right]^{6}}$
17.93 Hydrogenation of carbon-carbon $\pi$ bonds is important in the petroleum and food industries. The conversion of acetylene to ethylene is a simple example of the process:

$$
\mathrm{C}_{2} \mathrm{H}_{2}(g)+\mathrm{H}_{2}(g) \rightleftharpoons \mathrm{C}_{2} \mathrm{H}_{4}(g)
$$

The calculated $K_{\mathrm{c}}$ at 2000 . K is $2.9 \times 10^{8}$. But the process is run at lower temperatures with the aid of a catalyst to prevent decomposition. Use $\Delta H_{\mathrm{f}}^{\circ}$ values to calculate the $K_{\mathrm{c}}$ at 300 . K.
17.94 For the reaction $\mathrm{M}_{2}+\mathrm{N}_{2} \rightleftharpoons 2 \mathrm{MN}$, scene A represents the mixture at equilibrium, with M black and N orange. If each molecule represents 0.10 mol and the volume is 1.0 L , how many moles of each substance will be present in scene B when that mixture reaches equilibrium?

17.95 Highly toxic disulfur decafluoride decomposes by a freeradical process: $\mathrm{S}_{2} \mathrm{~F}_{10}(g) \rightleftharpoons \mathrm{SF}_{4}(g)+\mathrm{SF}_{6}(g)$. In a study of the decomposition, $\mathrm{S}_{2} \mathrm{~F}_{10}$ was placed in a 2.0-L flask and heated to $100^{\circ} \mathrm{C}$; $\left[\mathrm{S}_{2} \mathrm{~F}_{10}\right]$ was 0.50 M at equilibrium. More $\mathrm{S}_{2} \mathrm{~F}_{10}$ was added, and when equilibrium was reattained, $\left[\mathrm{S}_{2} \mathrm{~F}_{10}\right]$ was 2.5 M . How did $\left[\mathrm{SF}_{4}\right]$ and $\left[\mathrm{SF}_{6}\right]$ change from the original to the new equilibrium position after the addition of more $\mathrm{S}_{2} \mathrm{~F}_{10}$ ?
17.96 A study of the water-gas shift reaction (see Problem 17.37) was made in which equilibrium was reached with $[\mathrm{CO}]=$ $\left[\mathrm{H}_{2} \mathrm{O}\right]=\left[\mathrm{H}_{2}\right]=0.10 \mathrm{M}$ and $\left[\mathrm{CO}_{2}\right]=0.40 \mathrm{M}$. After 0.60 mol of $\mathrm{H}_{2}$ is added to the 2.0-L container and equilibrium is re-established, what are the new concentrations of all the components?
17.97 A gaseous mixture of 10.0 volumes of $\mathrm{CO}_{2}, 1.00$ volume of unreacted $\mathrm{O}_{2}$, and 50.0 volumes of unreacted $\mathrm{N}_{2}$ leaves an engine at 4.0 atm and 800 K . Assuming that the mixture reaches $\mathbf{D}$ equilibrium, what are (a) the partial pressure and (b) the concentration (in picograms per liter, $\mathrm{pg} / \mathrm{L}$ ) of CO in this exhaust gas? $2 \mathrm{CO}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{CO}(\mathrm{g})+\mathrm{O}_{2}(\mathrm{~g}) \quad K_{\mathrm{p}}=1.4 \times 10^{-28}$ at $800 . \mathrm{K}$ (The actual concentration of CO in exhaust gas is much higher because the gases do not reach equilibrium in the short transit time through the engine and exhaust system.)
17.98 Consider the following reaction:

$$
3 \mathrm{Fe}(s)+4 \mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons \mathrm{Fe}_{3} \mathrm{O}_{4}(s)+4 \mathrm{H}_{2}(g)
$$

(a) What is the apparent oxidation state of Fe in $\mathrm{Fe}_{3} \mathrm{O}_{4}$ ?
(b) Actually, Fe has two oxidation states in $\mathrm{Fe}_{3} \mathrm{O}_{4}$. What are they?
(c) At $900^{\circ} \mathrm{C}, K_{\mathrm{c}}$ for the reaction is 5.1 . If 0.050 mol of $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ and 0.100 mol of $\mathrm{Fe}(s)$ are placed in a $1.0-\mathrm{L}$ container at $900^{\circ} \mathrm{C}$, how many grams of $\mathrm{Fe}_{3} \mathrm{O}_{4}$ are present at equilibrium?

Note: The synthesis of ammonia is a major process throughout the industrialized world. Problems 17.99 to 17.105 refer to various aspects of this all-important reaction:

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-91.8 \mathrm{~kJ}
$$

17.99 When ammonia is made industrially, the mixture of $\mathrm{N}_{2}, \mathrm{H}_{2}$, and $\mathrm{NH}_{3}$ that emerges from the reaction chamber is far from equilibrium. Why does the plant supervisor use reaction conditions that produce less than the maximum yield of ammonia?
17.100 The following reaction can be used to make $\mathrm{H}_{2}$ for the synthesis of ammonia from the greenhouse gases carbon dioxide and methane:

$$
\mathrm{CH}_{4}(g)+\mathrm{CO}_{2}(g) \rightleftharpoons 2 \mathrm{CO}(g)+2 \mathrm{H}_{2}(g)
$$

(a) What is the percent yield of $\mathrm{H}_{2}$ when an equimolar mixture of $\mathrm{CH}_{4}$ and $\mathrm{CO}_{2}$ with a total pressure of 20.0 atm reaches equilibrium at 1200 . K, at which $K_{\mathrm{p}}=3.548 \times 10^{6}$ ?
(b) What is the percent yield of $\mathrm{H}_{2}$ for this system at $1300 . \mathrm{K}$, at which $K_{\mathrm{p}}=2.626 \times 10^{7}$ ?
(c) Use the van't Hoff equation to find $\Delta H_{\mathrm{rxn}}^{\circ}$.
17.101 The methane used to obtain $\mathrm{H}_{2}$ for $\mathrm{NH}_{3}$ manufacture is impure and usually contains other hydrocarbons, such as propane, $\mathrm{C}_{3} \mathrm{H}_{8}$. Imagine the reaction of propane occurring in two steps:

$$
\begin{gathered}
\mathrm{C}_{3} \mathrm{H}_{8}(g)+3 \mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons 3 \mathrm{CO}(g)+7 \mathrm{H}_{2}(g) \\
K_{\mathrm{p}}=8.175 \times 10^{15} \text { at } 1200 . \mathrm{K} \\
\mathrm{CO}(g)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons \mathrm{CO}_{2}(g)+\mathrm{H}_{2}(g) \\
K_{\mathrm{p}}=0.6944 \text { at } 1200 . \mathrm{K}
\end{gathered}
$$

(a) Write the overall equation for the reaction of propane and steam to produce carbon dioxide and hydrogen.
(b) Calculate $K_{\mathrm{p}}$ for the overall process at 1200 . K.
(c) When 1.00 volume of $\mathrm{C}_{3} \mathrm{H}_{8}$ and 4.00 volumes of $\mathrm{H}_{2} \mathrm{O}$, each at 1200. K and 5.0 atm , are mixed in a container, what is the final pressure? Assume the total volume remains constant, that the reaction is essentially complete, and that the gases behave ideally. (d) What percentage of the $\mathrm{C}_{3} \mathrm{H}_{8}$ remains unreacted?
17.102 Using $\mathrm{CH}_{4}$ and steam as a source of $\mathrm{H}_{2}$ for $\mathrm{NH}_{3}$ synthesis requires high temperatures. Rather than burning $\mathrm{CH}_{4}$ separately to heat the mixture, it is more efficient to inject some $\mathrm{O}_{2}$ into the reaction mixture. All of the $\mathrm{H}_{2}$ is thus released for the synthesis, and the heat of reaction for the combustion of $\mathrm{CH}_{4}$ helps maintain the required temperature. Imagine the reaction occurring in two steps:

$$
\begin{aligned}
2 \mathrm{CH}_{4}(g)+\mathrm{O}_{2}(g) \rightleftharpoons & 2 \mathrm{CO}(g)+4 \mathrm{H}_{2}(g) \\
& K_{\mathrm{p}}=9.34 \times 10^{28} \text { at } 1000 . \mathrm{K} \\
\mathrm{CO}(g)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons & \mathrm{CO}_{2}(g)+\mathrm{H}_{2}(g) \\
& K_{\mathrm{p}}=1.374 \text { at } 1000 . \mathrm{K}
\end{aligned}
$$

(a)wite the aveafequation for the reaction of methane, steam, and oxygen to form carbon dioxide and hydrogen.
(b) What is $K_{\mathrm{p}}$ for the overall reaction?
(c) What is $K_{\mathrm{c}}$ for the overall reaction?
(d) A mixture of 2.0 mol of $\mathrm{CH}_{4}, 1.0 \mathrm{~mol}$ of $\mathrm{O}_{2}$, and 2.0 mol of steam with a total pressure of 30 . atm reacts at $1000 . \mathrm{K}$ at constant volume. Assuming that the reaction is complete and the ideal gas law is a valid approximation, what is the final pressure?
17.103 A mixture of 3.00 volumes of $\mathrm{H}_{2}$ and 1.00 volume of $\mathrm{N}_{2}$ reacts at $344^{\circ} \mathrm{C}$ to form ammonia. The equilibrium mixture at 110. atm contains $41.49 \% \mathrm{NH}_{3}$ by volume. Calculate $K_{\mathrm{p}}$ for the reaction, assuming that the gases behave ideally.
17.104 One mechanism for the synthesis of ammonia proposes that $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ molecules catalytically dissociate into atoms:

$$
\begin{array}{ll}
\mathrm{N}_{2}(g) \rightleftharpoons 2 \mathrm{~N}(g) & \log K_{\mathrm{p}}=-43.10 \\
\mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{H}(g) & \log K_{\mathrm{p}}=-17.30
\end{array}
$$

(a) Find the partial pressure of N in $\mathrm{N}_{2}$ at $1000 . \mathrm{K}$ and 200. atm.
(b) Find the partial pressure of H in $\mathrm{H}_{2}$ at $1000 . \mathrm{K}$ and 600. atm.
(c) How many N atoms and H atoms are present per liter?
(d) Based on these answers, which of the following is a more reasonable step to continue the mechanism after the catalytic dissociation? Explain.

$$
\begin{aligned}
\mathrm{N}(g) & +\mathrm{H}(g) \\
\mathrm{N}_{2}(g) & \longrightarrow \mathrm{HH}(g) \\
& \longrightarrow \mathrm{NH}(g)+\mathrm{N}(g)
\end{aligned}
$$

17.105 You are a member of a research team of chemists discussing the plans to operate an ammonia processing plant:

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
$$

(a) The plant operates at close to 700 K , at which $K_{\mathrm{p}}$ is $1.00 \times 10^{-4}$, and employs the stoichiometric $1 / 3$ ratio of $\mathrm{N}_{2} / \mathrm{H}_{2}$.

At equilibrium, the partial pressure of $\mathrm{NH}_{3}$ is 50 . atm. Calculate the partial pressures of each reactant and $P_{\text {total }}$.
(b) One member of the team suggests the following: since the partial pressure of $\mathrm{H}_{2}$ is cubed in the reaction quotient, the plant could produce the same amount of $\mathrm{NH}_{3}$ if the reactants were in a $1 / 6$ ratio of $\mathrm{N}_{2} / \mathrm{H}_{2}$ and could do so at a lower pressure, which would cut operating costs. Calculate the partial pressure of each reactant and $P_{\text {total }}$ under these conditions, assuming an unchanged partial pressure of 50 . atm for $\mathrm{NH}_{3}$. Is the suggestion valid?
17.106 The molecular scenes below depict the reaction $\mathrm{Y} \rightleftharpoons 2 \mathrm{Z}$ at four different times, out of sequence, as it reaches equilibrium. Each sphere ( Y is red and Z is green) represents 0.025 mol and the volume is 0.40 L . (a) Which scene(s) represent(s) equilibrium? (b) List the scenes in the correct sequence. (c) Calculate $K_{\mathrm{c}}$.

17.107 For the equilibrium

$$
\mathrm{H}_{2} \mathrm{~S}(g) \rightleftharpoons 2 \mathrm{H}_{2}(g)+\mathrm{S}_{2}(g) \quad K_{\mathrm{c}}=9.0 \times 10^{-8} \text { at } 700^{\circ} \mathrm{C}
$$

the initial concentrations of the three gases are $0.300 \mathrm{H}_{2} \mathrm{~S}$, $0.300 \mathrm{M} \mathrm{H}_{2}$, and $0.150 \mathrm{M}_{2}$. Determine the equilibrium concentrations of the gases.
17.108 The two most abundant atmospheric gases react to a tiny extent at 298 K in the presence of a catalyst:

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}(g) \quad K_{\mathrm{p}}=4.35 \times 10^{-31}
$$

(a) What are the equilibrium pressures of the three gases when the atmospheric partial pressures of $\mathrm{O}_{2}(0.210 \mathrm{~atm})$ and of $\mathrm{N}_{2}$ ( 0.780 atm ) are put into an evacuated $1.00-\mathrm{L}$ flask at 298 K with catalyst? (b) What is $P_{\text {total }}$ in the container? (c) Find $K_{\mathrm{c}}$ at 298 K .
17.109 The oxidation of nitrogen monoxide is favored at 457 K :

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}_{2}(g) \quad K_{\mathrm{p}}=1.3 \times 10^{4}
$$

(a) Calculate $K_{\mathrm{c}}$ at 457 K . (b) Find $\Delta H_{\mathrm{rxn}}^{\circ}$ from standard heats of formation. (c) At what temperature does $K_{\mathrm{c}}=6.4 \times 10^{9}$ ?
17.110 The kinetics and equilibrium of the decomposition of hydrogen iodide have been studied extensively:

$$
2 \mathrm{HI}(g) \rightleftharpoons \mathrm{H}_{2}(g)+\mathrm{I}_{2}(g)
$$

(a) At $298 \mathrm{~K}, K_{\mathrm{c}}=1.26 \times 10^{-3}$ for this reaction. Calculate $K_{\mathrm{p}}$.
(b) Calculate $K_{\mathrm{c}}$ for the formation of HI at 298 K .
(c) Calculate $\Delta H_{\mathrm{rxn}}^{\circ}$ for HI decomposition from $\Delta H_{\mathrm{f}}^{\circ}$ values.
(d) At $729 \mathrm{~K}, K_{\mathrm{c}}=2.0 \times 10^{-2}$ for HI decomposition. Calculate $\Delta H_{\mathrm{rxn}}$ for this reaction from the van't Hoff equation.
17.111 Isopentyl alcohol reacts with pure acetic acid to form isopentyl acetate, the essence of banana oil:

$$
\mathrm{C}_{5} \mathrm{H}_{11} \mathrm{OH}+\mathrm{CH}_{3} \mathrm{COOH} \rightleftharpoons \mathrm{CH}_{3} \mathrm{COOC}_{5} \mathrm{H}_{11}+\mathrm{H}_{2} \mathrm{O}
$$

A student adds a drying agent to remove $\mathrm{H}_{2} \mathrm{O}$ and thus increase the yield of banana oil. Is this approach reasonable? Explain.
17.112 Isomers $Q$ (blue) and $R$ (yellow) interconvert. They are depicted in an equilibrium mixture in scene A. Scene B represents the mixture after addition of more Q . How many molecules of each isomer are present when the mixture in scene B attains equilibrium again?

17.113 Many essential metabolites are products in branched pathways, such as the one shown below:

One method of control of these pathways occurs through inhibition of the first enzyme specific for a branch. (a) Which enzyme is inhibited by F? (b) Which enzyme is inhibited by I? (c) What is the disadvantage if F inhibited enzyme 1 ? (d) What is the disadvantage if F inhibited enzyme 6?
F17.114Glauber's salt, $\mathrm{Na}_{2} \mathrm{SO}_{4} \cdot 10 \mathrm{H}_{2} \mathrm{O}$, was used by J. R. Glauber in the $17^{\text {tr }}$ century as a medicinal agent. At $25^{\circ} \mathrm{C}, K_{\mathrm{p}}=4.08 \times 10^{-25}$ for the loss of water of hydration from Glauber's salt:

$$
\mathrm{Na}_{2} \mathrm{SO}_{4} \cdot 10 \mathrm{H}_{2} \mathrm{O}(s) \rightleftharpoons \mathrm{Na}_{2} \mathrm{SO}_{4}(s)+10 \mathrm{H}_{2} \mathrm{O}(g)
$$

(a) What is the vapor pressure of water at $25^{\circ} \mathrm{C}$ in a closed container holding a sample of $\mathrm{Na}_{2} \mathrm{SO}_{4} \cdot 10 \mathrm{H}_{2} \mathrm{O}(s)$ ?
(b) How do the following changes affect the ratio (higher, lower, same) of hydrated form to anhydrous form for the system above?
(1) Add more $\mathrm{Na}_{2} \mathrm{SO}_{4}(s)$
(2) Reduce the container volume
(3) Add more water vapor
(4) Add $\mathrm{N}_{2}$ gas
17.115 In a study of synthetic fuels, 0.100 mol of CO and 0.100 mol of water vapor are added to a $20.00-\mathrm{L}$ container at $900 .{ }^{\circ} \mathrm{C}$, and they react to form $\mathrm{CO}_{2}$ and $\mathrm{H}_{2}$. At equilibrium, [CO] is $2.24 \times 10^{-3} \mathrm{M}$. (a) Calculate $K_{\mathrm{c}}$ at this temperature. (b) Calculate $P_{\text {total }}$ in the flask at equilibrium. (c) How many moles of CO must be added to double this pressure? (d) After $P_{\text {total }}$ is doubled and the system reattains equilibrium, what is $[\mathrm{CO}]_{\mathrm{eq}}$ ?
17.116 Synthetic diamonds are made under conditions of high temperature ( 2000 K ) and high pressure ( $10^{10} \mathrm{~Pa} ; 10^{5} \mathrm{~atm}$ ) in the presence of catalysts. Carbon's phase diagram is useful for finding the conditions for formation of natural and synthetic diamonds. Along the diamond-graphite line, the two allotropes are in equilibrium. (a) At point A, what is the sign
 of $\Delta H$ for the formation of diamond from graphite? Explain. (b) Which allotrope is denser? Explain.

## 18

Gardening with Acid-Base Equilibria Hydrangea flowers contain a substance in their extracellular fluids that changes color depending on the acidity of the soil: Acidic soil produces reddish flowers, and basic soil yields bluish ones. In this chapter, we explore the essential nature of acids and bases and their extremely important equilibria.

18.8 Generalizing the Brønsted-Lowry Concept: The Leveling Effect
18.9 Electron-Pair Donation and the Lewis Acid-Base Definition
Molecules as Lewis Acids Metal Cations as Lewis Acids Overview of Acid-Base Definitions

Acids and bases have been used as laboratory chemicals since the time of the alchemists, and it is likely that their properties were being applied for at least a millenium before then. They remain indispensable, not only in academic and industrial labs, but in the home as well (Table 18.1).

Notice that some of the acids (e.g., acetic and citric) have a sour taste. In fact, sourness had been a defining property since the $17^{\text {th }}$ century: an acid was any substance that had a sour taste; reacted with active metals, such as aluminum and zinc, to produce hydrogen gas; and turned certain organic compounds characteristic colors. (We discuss indicators later and in Chapter 19.) A base was any substance that had a bitter taste and slippery feel and turned the same organic compounds different characteristic colors. (Please remember NEVER to taste or touch laboratory chemicals; instead, try some acetic acid in the form of vinegar on your next salad.) Moreover, it was known that when acids and bases react, each cancels the properties of the other in a process called neutralization. But limited definitions in science are replaced by broader ones as new phenomena are discovered. Although the early definitions of acids and bases described distinctive properties, they inevitably gave way to those based on molecular behavior.

IN THIS CHAPTER . . . We develop three definitions of acids and bases that allow us to understand ever-increasing numbers of reactions. In the process, we apply the principles of chemical equilibrium to this essential group of substances. After presenting the Arrhenius acid-base definition, we examine acid dissociation to see why acids vary in strength. The pH scale is introduced as a means of comparing the acidity or basicity of aqueous solutions. Then, we'll see that the Brønsted-Lowry acidbase definition greatly expands the meaning of "base," along with the scope of acid-base reactions. We use molecular structures of acids and bases to rationalize variations in their strengths and see that the very designations "acid" and "base" depend on relative strengths and on the solvent. Finally, we'll see that the Lewis acidbase definition expands the meaning of "acid" and acid-base behavior even further.

## Table 18.1 Some Common Acids and Bases and Their Household Uses

## Concepts \& Skills to Review before you study this chapter

- role of water as solvent (Section 4.1)
- writing ionic equations (Section 4.2)
- acids, bases, and acid-base reactions (Section 4.4)
- proton transfer in acid-base reactions (Section 4.4)
- properties of an equilibrium constant (Section 17.2)
- solving equilibrium problems (Section 17.5)

### 18.1 ACIDS AND BASES IN WATER

Although water is not an essential participant in all modern acid-base definitions, most laboratory work with acids and bases involves water, as do most environmental, biological, and industrial applications. Recall from our discussion in Chapter 4 that water is a product in all reactions between strong acids and strong bases:

$$
\mathrm{HCl}(a q)+\mathrm{NaOH}(a q) \longrightarrow \mathrm{NaCl}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Indeed, as the net ionic equation of this reaction shows, water is the product:

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
$$

Furthermore, whenever an acid dissociates in water, solvent molecules participate in the reaction:

$$
\mathrm{HA}(g \text { or } l)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{A}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)
$$

As you saw in that earlier discussion, water molecules surround the proton to form H -bonded species with the general formula $\mathrm{H}\left(\mathrm{H}_{2} \mathrm{O}\right)_{n}{ }^{+}$. Because the proton is so small, its charge density is very high, so its attraction to water is especially strong. The proton bonds covalently to one of the lone electron pairs of a water molecule's O atom to form a hydronium ion, $\mathbf{H}_{\mathbf{3}} \mathbf{O}^{+}$, which forms H bonds to several other water molecules (see Figure 4.7, p. 151). To emphasize the active role of water and the nature of the proton-water interaction, the hydrated proton is usually shown in the text as $\mathrm{H}_{3} \mathrm{O}^{+}(a q)$, although in some cases this hydrated species is shown more simply as $\mathrm{H}^{+}(a q)$.

## Release of $\mathrm{H}^{+}$or $\mathrm{OH}^{-}$and the Arrhenius Acid-Base Definition

The earliest and simplest definition of acids and bases that reflects their molecular haturefos stggested by'SvanteArfemits, whose work on the rate constant we encountered in Chapter 16. In the Arrhenius acid-base definition, acids and bases are classified in terms of their formulas and their behavior in water:

- An acid is a substance that has H in its formula and dissociates in water to yield $\mathrm{H}_{3} \mathrm{O}^{+}$.
- A base is a substance that has OH in its formula and dissociates in water to yield $\mathrm{OH}^{-}$.

Some typical Arrhenius acids are $\mathrm{HCl}, \mathrm{HNO}_{3}$, and HCN , and some typical bases are $\mathrm{NaOH}, \mathrm{KOH}$, and $\mathrm{Ba}(\mathrm{OH})_{2}$. Although Arrhenius bases contain discrete $\mathrm{OH}^{-}$ions in their structures, Arrhenius acids never contain discrete $\mathrm{H}^{+}$ions. On the contrary, these acids contain covalently bonded $H$ atoms that ionize when the molecule dissolves in water.

When an acid and a base react, they undergo neutralization. The meaning of acid-base reactions has changed along with the definitions of acid and base, but in the Arrhenius sense, neutralization occurs when the $H^{+}$ion from the acid and the $\mathrm{OH}^{-}$ion from the base combine to form $\mathrm{H}_{2} \mathrm{O}$. This description explains an observation that puzzled many of Arrhenius's colleagues. They observed that all neutralization reactions between what we now call strong acids and strong bases (those that dissociate completely in water) had the same heat of reaction. No matter which strong acid and base reacted, and no matter which salt formed, $\Delta H_{\mathrm{rxn}}^{\circ}$ was -55.9 kJ per mole of water formed. Arrhenius suggested that the heat of reaction was always the same because the actual reaction was always the same-a hydrogen ion and a hydroxide ion formed water:

$$
\mathrm{H}^{+}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-55.9 \mathrm{~kJ}
$$

The dissolved salt that formed along with the water, for example, NaCl in the reaction of sodium hydroxide with hydrochloric acid,

$$
\mathrm{Na}^{+}(a q)+\mathrm{OH}^{-}(a q)+\mathrm{H}^{+}(a q)+\mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{Na}^{+}(a q)+\mathrm{Cl}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

did not affect the $\Delta H_{\mathrm{rxn}}^{\circ}$ but existed as hydrated spectator ions.
Despite its importance at the time, limitations in the Arrhenius definition soon became apparent. Arrhenius and many others realized that even though some substances do not have discrete $\mathrm{OH}^{-}$ions, they still behave as bases. For example, $\mathrm{NH}_{3}$ and $\mathrm{K}_{2} \mathrm{CO}_{3}$ also yield $\mathrm{OH}^{-}$in water. As you'll see shortly, broader acidbase definitions are required to include these species.

## Variation in Acid Strength: The Acid-Dissociation Constant ( $K_{\mathrm{a}}$ )

Acids and bases differ greatly in their strength in water, that is, in the amount of $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$produced per mole of substance dissolved. We generally classify acids and bases as either strong or weak, according to the extent of their dissociation into ions in water (see Table 4.2, p. 151). Remember, however, that a gradation in strength exists, as we'll examine quantitatively in a moment. Acids and bases are electrolytes in water, so this classification of acid and base strength correlates with our earlier classification of electrolyte strength: strong electrolytes dissociate completely, and weak electrolytes dissociate partially.

- Strong acids dissociate completely into ions in water (Figure 18.1):

$$
\mathrm{HA}(g \text { or } l)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{A}^{-}(a q)
$$

In a dilute solution of a strong acid, virtually no HA molecules are present; that is, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \approx[\mathrm{HA}]_{\text {init }}$. In other words, $[\mathrm{HA}]_{\mathrm{eq}} \approx 0$, so the value of $K_{\mathrm{c}}$ is extremely large:

Because the reaction is essentially complete, it is not very useful to express it as an equilibrium process. In a dilute aqueous nitric acid solution, for example, there are virtually no undissociated nitric acid molecules:

$$
\mathrm{HNO}_{3}(l)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{NO}_{3}^{-}(a q)
$$

Figure 18.1 The extent of dissociation for strong acids. The bar graphs show the relative numbers of moles of species before (left) and after (right) acid dissociation occurs. When a strong acid dissolves in water, it dissociates completely, yielding $\mathrm{H}_{3} \mathrm{O}^{+}(a q)$ and $\mathrm{A}^{-}(a q)$ ions; virtually no HA molecules are present.

Animation: Dissociation of Strong and Weak Acids

- Weak acids dissociate very slightly into ions in water (Figure 18.2):

$$
\mathrm{HA}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{A}^{-}(a q)
$$

In a dilute solution of a weak acid, the great majority of HA molecules are undissociated. Thus, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \ll[\mathrm{HA}]_{\text {init. }}$. In other words, $[\mathrm{HA}]_{\mathrm{eq}} \approx[\mathrm{HA}]_{\text {init }}$, so the value of $K_{\mathrm{c}}$ is very small. Hydrocyanic acid is an example of a weak acid:

$$
\begin{gathered}
\mathrm{HCN}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{CN}^{-}(a q) \\
Q_{\mathrm{c}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{CN}^{-}\right]}{[\mathrm{HCN}]\left[\mathrm{H}_{2} \mathrm{O}\right]} \quad\left(\text { at equilibrium, } Q_{\mathrm{c}}=K_{\mathrm{c}} \ll 1\right)
\end{gathered}
$$

Figure 18.2 The extent of dissociation for weak acids. In contrast to a strong acid in water (see Figure 18.1), a weak acid dissociates very little, remaining mostly as intact acid molecules and, thus, yielding relatively few $\mathrm{H}_{3} \mathrm{O}^{+}(a q)$ and $\mathrm{A}^{-}(a q)$ ions.

Figure 18.3 Reaction of zinc with a strong and a weak acid. In the reaction of zinc with a strong acid (left), the higher concentration of $\mathrm{H}_{3} \mathrm{O}^{+}$results in rapid formation of $\mathrm{H}_{2}$ (bubbles). In a weak acid (right), the $\mathrm{H}_{3} \mathrm{O}^{+}$concentration is much lower, so formation of $\mathrm{H}_{2}$ is much slower.

(As in Chapter 17, brackets with no subscript mean molar concentration at equi-
 equilibrium, so instead of writing $Q$ and stating that $Q$ equals $K$ at equilibrium, we'll express $K$ directly as a collection of equilibrium concentration terms.)

Because of the effect of concentration on rate (Section 16.6), this dramatic difference in $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$causes a dramatic difference in the reaction rate when an equal concentration of a strong or a weak acid reacts with an active metal, such as zinc (Figure 18.3):

$$
\mathrm{Zn}(s)+2 \mathrm{H}_{3} \mathrm{O}^{+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{H}_{2}(g)
$$

In a strong acid, such as 1 MHCl , zinc reacts rapidly, forming bubbles of $\mathrm{H}_{2}$ vigorously. In a weak acid, such as $1 M \mathrm{CH}_{3} \mathrm{COOH}$, zinc reacts slowly, forming bubbles of $\mathrm{H}_{2}$ sluggishly on the metal piece. The strong acid has a much higher $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right.$] much more $\mathrm{H}_{3} \mathrm{O}^{+}$ion is available for reaction, so the rate is much higher.
The Meaning of $\boldsymbol{K}_{\mathrm{a}}$ There is a specific equilibrium constant for acid dissociation that highlights only those species whose concentrations change to any significant extent. The equilibrium expression for the dissociation of a general weak acid, $H A$, in water is

$$
K_{\mathrm{c}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]\left[\mathrm{H}_{2} \mathrm{O}\right]}
$$

In general, the concentration of water, $\left[\mathrm{H}_{2} \mathrm{O}\right]$, is so much larger than [HA] that it changes negligibly when HA dissociates; thus, it is treated as a constant. Therefore, as you saw for solids in Section 17.2, we simplify the equilibrium expression by multiplying $\left[\mathrm{H}_{2} \mathrm{O}\right]$ by $K_{c}$ to define a new equilibrium constant, the acid-dissociation constant (or acid-ionization constant), $\boldsymbol{K}_{\mathrm{a}}$ :

$$
\begin{equation*}
K_{\mathrm{c}}\left[\mathrm{H}_{2} \mathrm{O}\right]=K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]} \tag{18.1}
\end{equation*}
$$

Like any equilibrium constant, $K_{\mathrm{a}}$ is a number whose magnitude is temperature dependent and tells how far to the right the reaction has proceeded to reach equilibrium. Thus, the stronger the acid, the higher the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$at equilibrium, and the larger the $K_{\mathrm{a}}$ :

$$
\text { Stronger acid } \Longrightarrow \text { higher }\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \Longrightarrow \text { larger } K_{\mathrm{a}}
$$

The range of values for the acid-dissociation constants of weak acids extends over many orders of magnitude. Listed below are some benchmark $K_{\mathrm{a}}$ values for typical weak acids to give you a general idea of the fraction of HA molecules that dissociate into ions:

- For a weak acid with a relatively high $K_{\mathrm{a}}\left(\sim 10^{-2}\right)$, a 1 M solution has $\sim 10 \%$ of the HA molecules dissociated. The $K_{\mathrm{a}}$ of chlorous acid $\left(\mathrm{HClO}_{2}\right)$ is $1.1 \times 10^{-2}$, and 1 M HClO 2 is $10 . \%$ dissociated.
- For a weak acid with a moderate $K_{\mathrm{a}}\left(\sim 10^{-5}\right)$, a 1 M solution has $\sim 0.3 \%$ of the HA molecules dissociated. The $K_{\mathrm{a}}$ of acetic acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$ is $1.8 \times 10^{-5}$, and $1 \mathrm{M} \mathrm{CH}_{3} \mathrm{COOH}$ is $0.42 \%$ dissociated.
- For a weak acid with a relatively low $K_{\mathrm{a}}\left(\sim 10^{-10}\right)$, a 1 M solution has $\sim 0.001 \%$ of the HA molecules dissociated. The $K_{\mathrm{a}}$ of HCN is $6.2 \times 10^{-10}$, and $1 M \mathrm{HCN}$ is $0.0025 \%$ dissociated.

Thus, for solutions of the same initial HA concentration, the smaller the $K_{\mathrm{a}}$, the lower the percent dissociation of HA:

Smaller $K_{\mathrm{a}} \Longrightarrow$ lower $\%$ dissociation of HA $\Longrightarrow$ weaker acid
Table 18.2 lists $K_{\mathrm{a}}$ values in water of some weak monoprotic acids, those with one ionizable proton. (A more extensive list appears in Appendix C.) Strong acids are absent because they do not have meaningful $K_{\mathrm{a}}$ values. Note that the ionizable proton in organic acids is attached to oxygen in the -COOH group; the H atoms bonded to C atoms do not ienize. Section 48:4, we matus the bentivior of polyprotic acids, those with more than one ionizable proton.)

| Name (Formula) | Lewis Structure* | $K_{\text {a }}$ |  |
| :---: | :---: | :---: | :---: |
| Chlorous acid ( $\mathrm{HClO}_{2}$ ) | $\mathrm{H}-\underline{O}-\mathrm{C} \boldsymbol{C} \mid=\ddot{O}$ | $1.1 \times 10^{-2}$ | , |
| Nitrous acid ( $\mathrm{HNO}_{2}$ ) | $\mathrm{H}-\ddot{\mathrm{O}}-\ddot{\mathrm{N}}=\ddot{O}$ | $7.1 \times 10^{-4}$ |  |
| Hydrofluoric acid (HF) | H-F̈: | $6.8 \times 10^{-4}$ |  |
| Formic acid (HCOOH) |  | $1.8 \times 10^{-4}$ |  |
| Acetic acid ( $\mathrm{CH}_{3} \mathrm{COOH}$ ) |  | $1.8 \times 10^{-5}$ | ¢ |
| Propanoic acid ( $\left.\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{COOH}\right)$ |  | $1.3 \times 10^{-5}$ | 은 |
| Hypochlorous acid ( HClO ) | H-Ọ̈-C̣̈: | $2.9 \times 10^{-8}$ |  |
| Hydrocyanic acid (HCN) | $\mathrm{H}-\mathrm{C} \equiv \mathrm{N}$ : | $6.2 \times 10^{-10}$ |  |

*Red type indicates the ionizable proton; all atoms have zero formal charge.

## Classifying the Relative Strengths of Acids and Bases

Using a table of acid-dissociation constants is the surest way to quantify relative strengths of weak acids, but you can often classify acids and bases qualitatively as strong or weak just from their formulas:

- Strong acids. Two types of strong acids, with examples that you should memorize, are

1. The hydrohalic acids $\mathrm{HCl}, \mathrm{HBr}$, and HI
2. Oxoacids in which the number of O atoms exceeds the number of ionizable protons by two or more, such as $\mathrm{HNO}_{3}, \mathrm{H}_{2} \mathrm{SO}_{4}$, and $\mathrm{HClO}_{4}$; for example, in $\mathrm{H}_{2} \mathrm{SO}_{4}$, 4 O's -2 H 's $=2$

- Weak acids. There are many more weak acids than strong ones. Four types, with examples, are

1. The hydrohalic acid HF
2. Acids in which H is not bonded to O or to a halogen, such as HCN and $\mathrm{H}_{2} \mathrm{~S}$
3. Oxoacids in which the number of O atoms equals or exceeds by one the number of ionizable protons, such as $\mathrm{HClO}, \mathrm{HNO}_{2}$, and $\mathrm{H}_{3} \mathrm{PO}_{4}$
4. Carboxylic acids (general formula RCOOH , with the ionizable proton shown in red), such as $\mathrm{CH}_{3} \mathrm{COOH}$ and $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}$

- Strong bases. Water-soluble compounds containing $\mathrm{O}^{2-}$ or $\mathrm{OH}^{-}$ions are strong bases. The cations are usually those of the most active metals:

1. $\mathrm{M}_{2} \mathrm{O}$ or MOH , where $\mathrm{M}=$ Group $1 \mathrm{~A}(1)$ metal ( $\mathrm{Li}, \mathrm{Na}, \mathrm{K}, \mathrm{Rb}, \mathrm{Cs}$ )
2. MO or $\mathrm{M}(\mathrm{OH})_{2}$, where $\mathrm{M}=$ Group $2 \mathrm{~A}(2)$ metal $(\mathrm{Ca}, \mathrm{Sr}, \mathrm{Ba})$
[ MgO and $\mathrm{Mg}(\mathrm{OH})_{2}$ are only slightly soluble in water, but the soluble por-

## tion dissociates completely.] <br> AOAOO PDF HRNancer

- Weak bases. Many compounds with an electron-rich nitrogen atom are weak bases (none are Arrhenius bases). The common structural feature is an N atom with a lone electron pair (shown here in blue in the formulas):

1. Ammonia $\left(\mathrm{N}_{3}\right)$
2. Amines (general formula $\mathrm{R} \mathrm{N}_{2}, \mathrm{R}_{2} \stackrel{\mathrm{~N}}{\mathrm{H}}$, or $\mathrm{R}_{3} \stackrel{\mathrm{~N}}{ }$ ), such as $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{~N}_{2} \mathrm{H}_{2}$, $\left(\mathrm{CH}_{3}\right)_{2} \stackrel{\mathrm{~N}}{\mathrm{~N}}$, and $\left(\mathrm{C}_{3} \mathrm{H}_{7}\right)_{3} \stackrel{\mathrm{~N}}{ }$

## SAMPLE PROBLEM 18.1 Classifying Acid and Base Strength

 from the Chemical FormulaPROBLEM Classify each of the following compounds as a strong acid, weak acid, strong base, or weak base:
(a) $\mathrm{H}_{2} \mathrm{SeO}_{4}$
(b) $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHCOOH}$
(c) KOH
(d) $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHNH}_{2}$

PLAN We examine the formula and classify each acid or base, using the text descriptions. Particular points to note for acids are the numbers of O atoms relative to H atoms and the presence of the - COOH group. For bases, note the nature of the cation or the presence of an N atom that has a lone pair.
SOLUTION (a) Strong acid: $\mathrm{H}_{2} \mathrm{SeO}_{4}$ is an oxoacid in which the number of O atoms exceeds the number of ionizable protons by two.
(b) Weak acid: $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHCOOH}$ is a carboxylic acid, as indicated by the -COOH group.
(c) Strong base: KOH is one of the Group $1 \mathrm{~A}(1)$ hydroxides.
(d) Weak base: $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHNH}_{2}$ has a lone pair on the N and is an amine.

FOLLOW-UP PROBLEM 18.1 Which member of each pair is the stronger acid or base?
(a) HClO or $\mathrm{HClO}_{3}$
(b) HCl or $\mathrm{CH}_{3} \mathrm{COOH}$
(c) NaOH or $\mathrm{CH}_{3} \mathrm{NH}_{2}$

## Section Summary

In aqueous solution, water binds the proton released from an acid to form the hydrated species represented by $\mathrm{H}_{3} \mathrm{O}^{+}(a q)$. - In the Arrhenius definition, acids contain H and yield $\mathrm{H}_{3} \mathrm{O}^{+}$in water, bases contain OH and yield $\mathrm{OH}^{-}$in water, and an acid-base reaction (neutralization) is the reaction of $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$to form $\mathrm{H}_{2} \mathrm{O}$. • Acid strength depends on $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$relative to $[\mathrm{HA}]$ in aqueous solution. Strong acids dissociate completely and weak acids slightly. - The extent of dissociation is expressed by the acid-dissociation constant, $K_{\mathrm{a}}$. Weak acids have $K_{\mathrm{a}}$ values ranging from about $10^{-1}$ to $10^{-12}$. - Many acids and bases can be classified qualitatively as strong or weak based on their formulas.

### 18.2 AUTOIONIZATION OF WATER AND THE pH SCALE

Before we discuss the next major definition of acid-base behavior, let's examine a crucial property of water that enables us to quantify $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$in any aqueous system: water is an extremely weak electrolyte. The electrical conductivity of tap water is due almost entirely to dissolved ions, but even water that has been repeatedly distilled and deionized exhibits a tiny conductance. The reason is that water itself dissociates into ions very slightly in an equilibrium process known as autoionization (or self-ionization):

## The Equilibrium Nature of Autoionization: The Ion-Product Constant for Water ( $K_{w}$ )

Like any equilibrium process, the autoionization of water is described quantitatively by an equilibrium constant:

$$
K_{\mathrm{c}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{H}_{2} \mathrm{O}\right]^{2}}
$$

Because the concentration of $\mathrm{H}_{2} \mathrm{O}$ is essentially constant here, we simplify this equilibrium expression by including the constant $\left[\mathrm{H}_{2} \mathrm{O}\right]^{2}$ term with the value of $K_{\mathrm{c}}$ to obtain a new equilibrium constant, the ion-product constant for water, $K_{\mathbf{w}}$ :

$$
\begin{equation*}
K_{\mathrm{c}}\left[\mathrm{H}_{2} \mathrm{O}\right]^{2}=K_{\mathrm{w}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-14}\left(\text { at } 25^{\circ} \mathrm{C}\right) \tag{18.2}
\end{equation*}
$$

Notice that one $\mathrm{H}_{3} \mathrm{O}^{+}$ion and one $\mathrm{OH}^{-}$ion appear for each $\mathrm{H}_{2} \mathrm{O}$ molecule that dissociates. Therefore, in pure water, we find that

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\left[\mathrm{OH}^{-}\right]=\sqrt{1.0 \times 10^{-14}}=1.0 \times 10^{-7} M\left(\text { at } 25^{\circ} \mathrm{C}\right)
$$

Pure water has a concentration of about $55.5 M\left(\right.$ that is, $\left.\frac{1000 \mathrm{~g} / \mathrm{L}}{18.02 \mathrm{~g} / \mathrm{mol}}\right)$, so these equilibrium concentrations are attained when only 1 in 555 million water molecules dissociates reversibly into ions!

Autoionization of water has two major consequences for aqueous acid-base chemistry:

1. A change in $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$causes an inverse change in $\left[\mathrm{OH}^{-}\right]$, and vice versa:

Higher $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \Longrightarrow$ lower $\left[\mathrm{OH}^{-}\right]$and Higher $\left[\mathrm{OH}^{-}\right] \Longrightarrow$ lower $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$

Recall from our discussion of Le Châtelier's principle (Section 17.6) that a change in concentration of either ion shifts the equilibrium position, but it does not change the equilibrium constant. Therefore, if some acid is added, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$ increases, and so $\left[\mathrm{OH}^{-}\right]$must decrease; if some base is added, $\left[\mathrm{OH}^{-}\right]$increases, and so $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$must decrease. Note that the addition of $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$leads to the formation of $\mathrm{H}_{2} \mathrm{O}$, so the value of $K_{\mathrm{w}}$ is maintained.
2. Both ions are present in all aqueous systems. Thus, all acidic solutions contain a low concentration of $\mathrm{OH}^{-}$ions, and all basic solutions contain a low concentration of $\mathrm{H}_{3} \mathrm{O}^{+}$ions. The equilibrium nature of autoionization allows us to define "acidic" and "basic" solutions in terms of relative magnitudes of $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$ and $\left[\mathrm{OH}^{-}\right]$:

$$
\begin{array}{ll}
\text { In an acidic solution, } & {\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]>\left[\mathrm{OH}^{-}\right]} \\
\text {In a neutral solution, } & {\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right]} \\
\text {In a basic solution, } & {\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]<\left[\mathrm{OH}^{-}\right]}
\end{array}
$$

Figure 18.4 summarizes these relationships and the relative solution acidity. Moreover, if you know the value of $K_{\mathrm{w}}$ at a particular temperature and the concentration of one of these ions, you can easily calculate the concentration of the other ion by solving for it from the $K_{\mathrm{w}}$ expression:

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\frac{K_{\mathrm{w}}}{\left[\mathrm{OH}^{-}\right]} \quad \text { or } \quad\left[\mathrm{OH}^{-}\right]=\frac{K_{\mathrm{w}}}{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}
$$

Figure 18.4 The relationship between $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$and the relative acidity of solutions.

## SAMPLE PROBLEM 18.2 Calculating $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$or $\left[\mathrm{OH}^{-}\right]$in Aqueous Solution

PROBLEM A research chemist adds a measured amount of HCl gas to pure water at $25^{\circ} \mathrm{C}$ and obtains a solution with $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=3.0 \times 10^{-4} \mathrm{M}$. Calculate $\left[\mathrm{OH}^{-}\right]$. Is the solution neutral, acidic, or basic?
PLAN We use the known value of $K_{\mathrm{w}}$ at $25^{\circ} \mathrm{C}\left(1.0 \times 10^{-14}\right)$ and the given $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$ $\left(3.0 \times 10^{-4} M\right)$ to solve for $\left[\mathrm{OH}^{-}\right]$. Then we compare $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right.$] with $\left[\mathrm{OH}^{-}\right.$] to determine whether the solution is acidic, basic, or neutral (see Figure 18.4).
SOLUTION Calculating [ $\mathrm{OH}^{-}$]:

$$
\begin{aligned}
{\left[\mathrm{OH}^{-}\right] } & =\frac{K_{\mathrm{w}}}{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}=\frac{1.0 \times 10^{-14}}{3.0 \times 10^{-4}} \\
& =3.3 \times 10^{-11} \mathrm{M}
\end{aligned}
$$

Because $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]>\left[\mathrm{OH}^{-}\right]$, the solution is acidic.
CHECK It makes sense that adding an acid to water results in an acidic solution. Moreover, because $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$is greater than $10^{-7} \mathrm{M},\left[\mathrm{OH}^{-}\right]$must be less than $10^{-7} \mathrm{M}$ to give a constant $K_{\text {w }}$.
FOLLOW-UP PROBLEM 18.2 Calculate $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$in a solution that is at $25^{\circ} \mathrm{C}$ and has $\left[\mathrm{OH}^{-}\right]=6.7 \times 10^{-2} \mathrm{M}$. Is the solution neutral, acidic, or basic?

## Expressing the Hydronium Ion Concentration: The pH Scale

In aqueous solutions, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$can vary from about 10 M to $10^{-15} \mathrm{M}$. To handle numbers with negative exponents more conveniently in calculations, we convert them to positive numbers using a numerical system called a $p$-scale, the negative of the common (base-10) logarithm of the number. Applying this numerical system to $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$gives $\mathbf{p H}$, the negative logarithm of $\left[\mathrm{H}^{+}\right]\left(\right.$or $\left.\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\right)$:

$$
\begin{equation*}
\mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \tag{18.3}
\end{equation*}
$$

What is the pH of $10^{-12} \mathrm{M} \mathrm{H}_{3} \mathrm{O}^{+}$solution?

$$
\mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=-\log 10^{-12}=(-1)(-12)=12
$$

Similarly, a $10^{-3} \mathrm{M} \mathrm{H}_{3} \mathrm{O}^{+}$solution has a pH of 3 , and a $5.4 \times 10^{-4} \mathrm{M} \mathrm{H}_{3} \mathrm{O}^{+}$solution has a pH of 3.27:

$$
\mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=(-1)\left(\log 5.4+\log 10^{-4}\right)=3.27
$$

As with any measurement, the number of significant figures in a pH value reflects the precision with which the concentration is known. However, a pH value is a logarithm, so the number of significant figures in the concentration equals the number of digits to the right of the decimal point in the pH value (see Appendix A). In the preceding example, $5.4 \times 10^{-4} M$ has two significant figures, so its negative logarithm, 3.27, has two digits to the right of the decimal point.

Note in particular that the higher the pH , the lower the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$. Therefore, an acidic solution has a lower pH (higher $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$) than a basic solution. At $25^{\circ} \mathrm{C}$ in pure water, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$is $1.0 \times 10^{-7} \mathrm{M}$, so

$$
\begin{array}{ll}
\mathrm{pH} \text { of a neutral solution } & =7.00 \\
\mathrm{pH} \text { of an acidic solution } & <7.00 \\
\mathrm{pH} \text { of a basic solution } & >7.00
\end{array}
$$

 within a range of 0 to 14 .

Another important point arises when we compare $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$in different solutions. Because the pH scale is logarithmic, a solution of pH 1.0 has an $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$ that is 10 times higher than that of a pH 2.0 solution, 100 times higher than that of a pH 3.0 solution, and so forth. To find the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$from the pH , you perform the opposite arithmetic process; that is, you find the negative antilog of pH :

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-\mathrm{pH}}
$$

A p-scale is used to express other quantities as well:

- Hydroxide ion concentration can be expressed as pOH :

$$
\mathrm{pOH}=-\log \left[\mathrm{OH}^{-}\right]
$$

Acidic solutions have a higher pOH (lower $\left[\mathrm{OH}^{-}\right]$) than basic solutions.

- Equilibrium constants can be expressed as pK :

$$
\mathrm{p} K=-\log K
$$

A low $p K$ corresponds to a high $K$. A reaction that reaches equilibrium with mostly products present (proceeds far to the right) has a low $\mathrm{p} K$ (high $K$ ), whereas one that has mostly reactants present at equilibrium has a high $\mathrm{p} K$ (low $K$ ). Table 18.3 shows this relationship for aqueous equilibria of some weak acids.

| Table 18.3 The Relationship Between $\boldsymbol{K}_{\mathrm{a}}$ and $\mathrm{p} \boldsymbol{K}_{\mathrm{a}}$ |  |  |
| :--- | :---: | ---: |
| Acid Name (Formula) | $\boldsymbol{K}_{\mathrm{a}}$ at $25^{\circ} \mathrm{C}$ | $\mathrm{p} \boldsymbol{K}_{\mathrm{a}}$ |
| Hydrogen sulfate ion $\left(\mathrm{HSO}_{4}{ }^{-}\right)$ | $1.0 \times 10^{-2}$ | 1.99 |
| Nitrous acid $\left(\mathrm{HNO}_{2}\right)$ | $7.1 \times 10^{-4}$ | 3.15 |
| Acetic acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$ | $1.8 \times 10^{-5}$ | 4.74 |
| Hypobromous acid $(\mathrm{HBrO})$ | $2.3 \times 10^{-9}$ | 8.64 |
| Phenol $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}\right)$ | $1.0 \times 10^{-10}$ | 10.00 |

Figure 18.5 The pH values of some familiar aqueous solutions.

Figure 18.6 The relations among $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right], \mathrm{pH},\left[\mathrm{OH}^{-}\right]$, and pOH . Because $K_{w}$ is constant, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$are interdependent, and they change in opposite directions as the acidity or basicity of the aqueous solution increases. The pH and pOH are interdependent in the same way. Note that at $25^{\circ} \mathrm{C}$, the product of $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$is $1.0 \times 10^{-14}$, and the sum of pH and pOH is 14.00 .

The Relations Among $\mathbf{p H}, \mathbf{p O H}$, and $\mathbf{p} K_{\mathbf{w}}$ Taking the negative $\log$ of both sides of the $K_{\mathrm{w}}$ expression gives a very useful relationship among $\mathrm{p} K_{\mathrm{w}}, \mathrm{pH}$, and pOH :

$$
\begin{gather*}
K_{\mathrm{w}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-14}\left(\text { at } 25^{\circ} \mathrm{C}\right) \\
-\log K_{\mathrm{w}}=\left(-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\right)+\left(-\log \left[\mathrm{OH}^{-}\right]\right)=-\log \left(1.0 \times 10^{-14}\right) \\
\left.\quad \mathrm{p} K_{\mathrm{w}}=\mathrm{pH}+\mathrm{pOH}=14.00 \quad \text { (at } 25^{\circ} \mathrm{C}\right) \tag{18.4}
\end{gather*}
$$

Thesum of pH and ${ }^{\text {Ph }}$, the value of $\mathrm{p} K_{\mathrm{w}}$ equal to 14.00 at $25^{\circ} \mathrm{C}$. With $\mathrm{pH}, \mathrm{pOH},\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$, and $\left[\mathrm{OH}^{-}\right]$ interrelated through $K_{\mathrm{w}}$, knowing any one of the values allows us to determine the others (Figure 18.6).

## SAMPLE PROBLEM 18.3 Calculating $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right], \mathrm{pH},\left[\mathrm{OH}^{-}\right]$, and pOH

PROBLEM In an art restoration project, a conservator prepares copper-plate etching solutions by diluting concentrated $\mathrm{HNO}_{3}$ to $2.0 \mathrm{M}, 0.30 \mathrm{M}$, and 0.0063 M HNO 3 . Calculate $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right], \mathrm{pH},\left[\mathrm{OH}^{-}\right]$, and pOH of the three solutions at $25^{\circ} \mathrm{C}$.
PLAN We know from its formula that $\mathrm{HNO}_{3}$ is a strong acid, so it dissociates completely; thus, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\left[\mathrm{HNO}_{3}\right]_{\text {init. }}$. We use the given concentrations and the value of $K_{\mathrm{w}}$ at $25^{\circ} \mathrm{C}$ $\left(1.0 \times 10^{-14}\right)$ to find $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$and then use them to calculate pH and pOH . SOLUTION Calculating the values for $2.0 \mathrm{M} \mathrm{HNO}_{3}$ :

$$
\begin{aligned}
{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] } & =2.0 \mathrm{M} \\
\mathrm{pH} & =-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=-\log 2.0=-0.30 \\
{\left[\mathrm{OH}^{-}\right] } & =\frac{K_{\mathrm{w}}}{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}=\frac{1.0 \times 10^{-14}}{2.0}=5.0 \times 10^{-15} \mathrm{M} \\
\mathrm{pOH} & =-\log \left(5.0 \times 10^{-15}\right)=14.30
\end{aligned}
$$

Calculating the values for $0.30 \mathrm{M} \mathrm{HNO}_{3}$ :

$$
\begin{aligned}
{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] } & =0.30 \mathrm{M} \\
\mathrm{pH} & =-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=-\log 0.30=0.52 \\
{\left[\mathrm{OH}^{-}\right] } & =\frac{K_{\mathrm{w}}}{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}=\frac{1.0 \times 10^{-14}}{0.30}=3.3 \times 10^{-14} \mathrm{M} \\
\mathrm{pOH} & =-\log \left(3.3 \times 10^{-14}\right)=13.48
\end{aligned}
$$

Calculating the values for $0.0063 \mathrm{M} \mathrm{HNO}_{3}$ :

$$
\begin{aligned}
{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] } & =6.3 \times 10^{-3} \mathrm{M} \\
\mathrm{pH} & =-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=-\log \left(6.3 \times 10^{-3}\right)=2.20 \\
{\left[\mathrm{OH}^{-}\right] } & =\frac{K_{\mathrm{w}}}{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}=\frac{1.0 \times 10^{-14}}{6.3 \times 10^{-3}}=1.6 \times 10^{-12} \mathrm{M} \\
\mathrm{pOH} & =-\log \left(1.6 \times 10^{-12}\right)=11.80
\end{aligned}
$$

CHECK As the solution becomes more dilute, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$decreases, so pH increases, as we expect. An $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$greater than 1.0 M , as in $2.0 \mathrm{M} \mathrm{HNO}_{3}$, gives a positive $\log$, so it results in a negative pH . The arithmetic seems correct because $\mathrm{pH}+\mathrm{pOH}=14.00$ in each case. COMMENT On most calculators, finding the pH requires several keystrokes. For example, to find the pH of $6.3 \times 10^{-3} M \mathrm{HNO}_{3}$ solution, you enter: 6.3 , EXP, $3,+/-, \log ,+/-$.
FOLLOW-UP PROBLEM 18.3 A solution of NaOH has a pH of 9.52 . What is its $\mathrm{pOH},\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$, and $\left[\mathrm{OH}^{-}\right]$at $25^{\circ} \mathrm{C}$ ?

Measuring pH In the laboratory, pH values are usually obtained with an acid-base indicator or, more precisely, with an instrument called a pH meter. Acid-base indicators are organic molecules whose colors depend on the acidity or basicity of the solution in which they are dissolved. The pH of a solution is estimated quickly with $p H$ paper, a paper strip impregnated with one or a mixture of indicators. A drop of test solution is placed on the paper strip, and the color of the strip is compared with a color chart, as shown in Figure 18.7A.

The pH meter measures $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$by means of two electrodes immersed in the test solution. One electrode provides a stable reference voltage; the other has an extremely thin, conducting, glass membrane that separates a known internal $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$from the unknown external $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$. The difference in $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$creates a
 units (Figure 18.7B). We examine this device further in Chapter 21.

## Section Summary

Pure water has a low conductivity because it autoionizes to a small extent. This process is described by an equilibrium reaction whose equilibrium constant is the ionproduct constant for water, $K_{w}\left(1.0 \times 10^{-14}\right.$ at $\left.25^{\circ} \mathrm{C}\right)$. Thus, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$are inversely related: in acidic solution, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$is greater than $\left[\mathrm{OH}^{-}\right]$; the reverse is true in basic solution; and the two are equal in neutral solution. - To express small values of $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$more simply, we use the pH scale $\left(\mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\right)$. A high pH represents a low $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$. Similarly, $\mathrm{pOH}=-\log \left[\mathrm{OH}^{-}\right]$, and $\mathrm{pK}=-\log K$. In acidic solutions, $\mathrm{pH}<7.00$; in basic solutions, $\mathrm{pH}>7.00$; and in neutral solutions, $\mathrm{pH}=7.00$. The sum of pH and pOH equals $\mathrm{p} K_{\mathrm{w}}\left(14.00\right.$ at $25^{\circ} \mathrm{C}$ ).

### 18.3 PROTON TRANSFER AND THE BRØNSTED-LOWRY ACID-BASE DEFINITION

Earlier we noted a major shortcoming of the Arrhenius acid-base definition: many substances that yield $\mathrm{OH}^{-}$ions when they dissolve in water do not contain OH in their formulas. Examples include ammonia, the amines, and many salts of weak acids, such as NaF . Another limitation of the Arrhenius definition was that water had to be the solvent for acid-base reactions. In the early $20^{\text {th }}$ century, J. N. Brønsted and T. M. Lowry suggested definitions that remove these limitations. (Recall that we discussed their ideas briefly in Section 4.4.) According to the BrønstedLowry acid-base definition,

- An acid is a proton donor, any species that donates an $H^{+}$ion. An acid must contain H in its formula; $\mathrm{HNO}_{3}$ and $\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}$are two of many examples. All Arrhenius acids are Brønsted-Lowry acids.

A

B
Figure 18.7 Methods for measuring the pH of an aqueous solution. $\mathrm{A}, \mathrm{A}$ few drops of the solution are placed on a strip of pH paper, and the color is compared with the color chart. B, The electrodes of a pH meter immersed in the test solution measure $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$. (In this instrument, the two electrodes are housed in one probe.)

- A base is a proton acceptor, any species that accepts an $\mathrm{H}^{+}$ion. A base must contain a lone pair of electrons to bind the $\mathrm{H}^{+}$ion; a few examples are $\mathrm{NH}_{3}$, $\mathrm{CO}_{3}{ }^{2-}$, and $\mathrm{F}^{-}$, as well as $\mathrm{OH}^{-}$itself. Brønsted-Lowry bases are not Arrhenius bases, but all Arrhenius bases contain the Brønsted-Lowry base $\mathrm{OH}^{-}$.
From the Brønsted-Lowry perspective, the only requirement for an acid-base reaction is that one species donates a proton and another species accepts it: an acid-base reaction is a proton-transfer process. Acid-base reactions can occur between gases, in nonaqueous solutions, and in heterogeneous mixtures, as well as in aqueous solutions.

An acid and a base always work together in the transfer of a proton. In other words, one species behaves as an acid and the other species behaves as a base simultaneously. Even when an acid or a base merely dissolves in water, an acidbase reaction occurs because water acts as the other partner. Consider two typical acidic and basic solutions:

1. Acid donates a proton to water (Figure 18.8A). When HCl dissolves in water, an $\mathrm{H}^{+}$ion (a proton) is transferred from HCl to $\mathrm{H}_{2} \mathrm{O}$, where it becomes attached to a lone pair of electrons on the O atom, forming $\mathrm{H}_{3} \mathrm{O}^{+}$. In effect, HCl (the acid) has donated the $\mathrm{H}^{+}$, and $\mathrm{H}_{2} \mathrm{O}$ (the base) has accepted it:

$$
\mathrm{HCl}(g)+\mathrm{H}_{2} \ddot{\ddot{( }}(\mathrm{l}) \longrightarrow \mathrm{Cl}^{-}(a q)+\mathrm{H}_{3} \ddot{\mathrm{O}}^{+}(a q)
$$

2. Base accepts a proton from water (Figure 18.8B). Proton transfer also occurs in an aqueous solution of ammonia. $\mathrm{An} \mathrm{H}^{+}$from $\mathrm{H}_{2} \mathrm{O}$ attaches to the lone pair of N , forming $\mathrm{NH}_{4}{ }^{+}$. Having transferred an $\mathrm{H}^{+}$, the $\mathrm{H}_{2} \mathrm{O}$ becomes an $\mathrm{OH}^{-}$ion:

$$
\ddot{\mathrm{N}} \mathrm{H}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

In this case, $\mathrm{H}_{2} \mathrm{O}$ (the acid) has donated the $\mathrm{H}^{+}$, and $\mathrm{NH}_{3}$ (the base) has accepted it. Thus, $\mathrm{H}_{2} \mathrm{O}$ is amphiprotic: it acts as a base (accepts an $\mathrm{H}^{+}$) in one
 species are amphiprotic as well.

Figure 18.8 Proton transfer as the essential feature of a Brønsted-Lowry acid-base reaction. A, When HCl dissolves in water, it acts as an acid by donating a proton to water, which acts as a base by accepting it. B, In aqueous solution, $\mathrm{NH}_{3}$ acts as a base by accepting a proton from water, which acts as an acid by donating it. Thus, in the BronstedLowry sense, an acid-base reaction occurs in both cases.

## The Conjugate Acid-Base Pair

The Brønsted-Lowry definition provides a new way to look at acid-base reactions because it focuses on the reactants and the products. For example, let's examine the reaction between hydrogen sulfide and ammonia:

$$
\mathrm{H}_{2} \mathrm{~S}+\mathrm{NH}_{3} \rightleftharpoons \mathrm{HS}^{-}+\mathrm{NH}_{4}^{+}
$$

In the forward reaction, $\mathrm{H}_{2} \mathrm{~S}$ acts as an acid by donating an $\mathrm{H}^{+}$to $\mathrm{NH}_{3}$, which acts as a base by accepting. The reverse reaction involves another acid-base pair. The ammonium ion, $\mathrm{NH}_{4}^{+}$, acts as an acid by donating an $\mathrm{H}^{+}$to the hydrogen
sulfide ion, $\mathrm{HS}^{-}$, which acts as a base. Notice that the acid, $\mathrm{H}_{2} \mathrm{~S}$, becomes a base, $\mathrm{HS}^{-}$, and the base, $\mathrm{NH}_{3}$, becomes an acid, $\mathrm{NH}_{4}{ }^{+}$.

In Brønsted-Lowry terminology, $\mathrm{H}_{2} \mathrm{~S}$ and $\mathrm{HS}^{-}$are a conjugate acid-base pair: $\mathrm{HS}^{-}$is the conjugate base of the acid $\mathrm{H}_{2} \mathrm{~S}$. Similarly, $\mathrm{NH}_{3}$ and $\mathrm{NH}_{4}{ }^{+}$form a conjugate acid-base pair: $\mathrm{NH}_{4}{ }^{+}$is the conjugate acid of the base $\mathrm{NH}_{3}$. Every acid has a conjugate base, and every base has a conjugate acid. Note that, for any conjugate acid-base pair,

- The conjugate base has one fewer H and one more minus charge than the acid.
- The conjugate acid has one more H and one fewer minus charge than the base.

A Brønsted-Lowry acid-base reaction occurs when an acid and a base react to form their conjugate base and conjugate acid, respectively:

$$
\operatorname{acid}_{1}+\text { base }_{2} \rightleftharpoons \text { base }_{1}+\text { acid }_{2}
$$

Table 18.4 shows some Brønsted-Lowry acid-base reactions. Notice that

- Each reaction has an acid and a base as reactants and as products, and these comprise two conjugate acid-base pairs.
- Acids and bases can be neutral, cationic, or anionic.
- The same species can be an acid or a base (amphiprotic), depending on the other species reacting. Water behaves this way in reactions 1 and 4 , and $\mathrm{HPO}_{4}{ }^{2-}$ does so in reactions 4 and 6.

Table 18.4 The Conjugate Pairs in Some Acid-Base Reactions

|  | Conjugate Pair |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Acid | + | Base | $\Longrightarrow \text { Base }$ | + | Acid |
|  |  |  |  | Conjugate Pair |  |  |
| Reaction 1 | HF | + | $\mathrm{AH}_{2} \mathrm{H}_{2}{ }^{\circ}$ | PDE $\mathrm{F}^{-} \mathrm{E}^{\prime}$ |  | H30 ${ }^{\text {² }}$ |
| Reaction 2 | HCOOH | + | $\mathrm{CN}^{-}$ | $\mathrm{HCOO}^{-}$ | + | HCN |
| Reaction 3 | $\mathrm{NH}_{4}{ }^{+}$ | + | $\mathrm{CO}_{3}{ }^{2-}$ | $\mathrm{NH}_{3}$ | + | $\mathrm{HCO}_{3}{ }^{-}$ |
| Reaction 4 | $\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}$ | $+$ | $\mathrm{OH}^{-}$ | $\mathrm{HPO}_{4}{ }^{2-}$ | + | $\mathrm{H}_{2} \mathrm{O}$ |
| Reaction 5 | $\mathrm{H}_{2} \mathrm{SO}_{4}$ | $+$ | $\mathrm{N}_{2} \mathrm{H}_{5}{ }^{+}$ | $\mathrm{HSO}_{4}{ }^{-}$ | + | $\mathrm{N}_{2} \mathrm{H}_{6}{ }^{+}$ |
| Reaction 6 | $\mathrm{HPO}_{4}{ }^{2-}$ | $+$ | $\mathrm{SO}_{3}{ }^{2-}$ | $\mathrm{PO}_{4}{ }^{3-}$ | + | $\mathrm{HSO}_{3}{ }^{-}$ |

## SAMPLE PROBLEM 18.4 Identifying Conjugate Acid-Base Pairs

PROBLEM The following reactions are important environmental processes. Identify the conjugate acid-base pairs.
(a) $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q)+\mathrm{CO}_{3}{ }^{2-}(a q) \rightleftharpoons \mathrm{HCO}_{3}^{-}(a q)+\mathrm{HPO}_{4}{ }^{2-}(a q)$
(b) $\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{SO}_{3}{ }^{2-}(a q) \rightleftharpoons \mathrm{OH}^{-}(a q)+\mathrm{HSO}_{3}^{-}(a q)$

PLAN To find the conjugate pairs, we find the species that donated an $\mathrm{H}^{+}$(acid) and the species that accepted it (base). The acid (or base) on the left becomes its conjugate base (or conjugate acid) on the right. Remember, the conjugate acid has one more H and one fewer minus charge than its conjugate base.
SOLUTION (a) $\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}$has one more $\mathrm{H}^{+}$than $\mathrm{HPO}_{4}{ }^{2-} ; \mathrm{CO}_{3}{ }^{2-}$ has one fewer $\mathrm{H}^{+}$than $\mathrm{HCO}_{3}{ }^{-}$. Therefore, $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}$and $\mathrm{HCO}_{3}{ }^{-}$are the acids, and $\mathrm{HPO}_{4}{ }^{2-}$ and $\mathrm{CO}_{3}{ }^{2-}$ are the bases. The conjugate acid-base pairs are $\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-} / \mathrm{HPO}_{4}{ }^{2-}$ and $\mathrm{HCO}_{3}{ }^{-} / \mathrm{CO}_{3}{ }^{2-}$.
(b) $\mathrm{H}_{2} \mathrm{O}$ has one more $\mathrm{H}^{+}$than $\mathrm{OH}^{-} ; \mathrm{SO}_{3}{ }^{2-}$ has one fewer $\mathrm{H}^{+}$than $\mathrm{HSO}_{3}{ }^{-}$. The acids are $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{HSO}_{3}{ }^{-}$; the bases are $\mathrm{OH}^{-}$and $\mathrm{SO}_{3}{ }^{2-}$. The conjugate acid-base pairs are $\mathrm{H}_{2} \mathrm{O} / \mathrm{OH}^{-}$and $\mathrm{HSO}_{3}{ }^{-} / \mathrm{SO}_{3}{ }^{2-}$.
FOLLOW-UP PROBLEM 18.4 Identify the conjugate acid-base pairs:
(a) $\mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COO}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)$
(b) $\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{F}^{-}(a q) \rightleftharpoons \mathrm{OH}^{-}(a q)+\mathrm{HF}(a q)$

## Relative Acid-Base Strength and the Net Direction of Reaction

The net direction of an acid-base reaction depends on the relative strengths of the acids and bases involved. A reaction proceeds to the greater extent in the direction in which a stronger acid and stronger base form a weaker acid and weaker base. If the stronger acid and base are written on the left, the net direction is to the right, so $K_{\mathrm{c}}>1$.

The net direction of the reaction of $\mathrm{H}_{2} \mathrm{~S}$ and $\mathrm{NH}_{3}$ is to the right $\left(K_{\mathrm{c}}>1\right)$ because $\mathrm{H}_{2} \mathrm{~S}$ is a stronger acid than $\mathrm{NH}_{4}{ }^{+}$, the other acid present, and $\mathrm{NH}_{3}$ is a stronger base than $\mathrm{HS}^{-}$, the other base:

You might think of the process as a competition for the proton between the two bases, $\mathrm{NH}_{3}$ and $\mathrm{HS}^{-}$, in which $\mathrm{NH}_{3}$ wins.

In the same sense, the extent of acid (HA) dissociation in water depends on a competition for the proton between the two bases, $\mathrm{A}^{-}$and $\mathrm{H}_{2} \mathrm{O}$, and strong acids and weak acids give very different results. When the strong acid $\mathrm{HNO}_{3}$ dissolves, it completely transfers an $\mathrm{H}^{+}$to the base, $\mathrm{H}_{2} \mathrm{O}$, forming the conjugate base of $\mathrm{HNO}_{3}$, which is $\mathrm{NO}_{3}{ }^{-}$, and the conjugate acid of $\mathrm{H}_{2} \mathrm{O}$, which is $\mathrm{H}_{3} \mathrm{O}^{+}$:

$$
\mathrm{HNO}_{3}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{NO}_{3}^{-}+\mathrm{H}_{3} \mathrm{O}^{+}
$$

(In this case, the net direction is so far to the right that it would be inappropriate to show an equilibrium arrow.) $\mathrm{HNO}_{3}$ is a stronger acid than $\mathrm{H}_{3} \mathrm{O}^{+}$, and $\mathrm{H}_{2} \mathrm{O}$ is a stronger base than $\mathrm{NO}_{3}{ }^{-}$. Thus, with strong acids, the $\mathrm{H}_{2} \mathrm{O}$ wins the competition for the proton because $\mathrm{A}^{-}\left(\mathrm{NO}_{3}{ }^{-}\right)$is a much weaker base. On the other hand, with weak acids such as HF , the $\mathrm{A}^{-}\left(\mathrm{F}^{-}\right)$wins the competition because it is Apsungeobasethari $\mathrm{H}_{2}$ enhancer
$\mathrm{HF}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \underset{\text { weaker acid }+ \text { weaker base }}{\rightleftharpoons} \mathrm{F}^{-}+\mathrm{H}_{3} \mathrm{O}^{+}$
stronger base + stronger acid

Based on evidence gathered from the results of many such reactions, we can rank conjugate pairs in terms of the ability of the acid to transfer its proton (Figure 18.9). Note, especially, that a weaker acid has a stronger conjugate base. This makes perfect sense: the acid gives up its proton less readily because its conjugate base holds it more strongly.

We can use this list to predict the direction of a reaction between any two pairs, in other words, whether the equilibrium position lies predominantly to the right $\left(K_{\mathrm{c}}>1\right)$ or to the left $\left(K_{\mathrm{c}}<1\right)$. An acid-base reaction proceeds to the right if the acid reacts with a base that is lower on the list because this combination produces a weaker conjugate base and a weaker conjugate acid. Here are two sample problems, one using formulas and the other molecular scenes, that demonstrate this key idea.

SAMPLE PROBLEM 18.5 Predicting the Net Direction of an Acid-Base Reaction
PROBLEM Predict the net direction and whether $K_{\mathrm{c}}$ is greater or less than 1 for each of the following reactions (assume equal initial concentrations of all species):
(a) $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q)+\mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{NH}_{4}{ }^{+}(a q)+\mathrm{HPO}_{4}{ }^{2-}(a q)$
(b) $\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{HS}^{-}(a q) \rightleftharpoons \mathrm{OH}^{-}(a q)+\mathrm{H}_{2} \mathrm{~S}(a q)$

PLAN We first identify the conjugate acid-base pairs. To predict the direction, we consult Figure 18.9 to see which acid and base are stronger. The stronger acid and base form the weaker acid and base, so the reaction proceeds in that net direction. If the reaction as written proceeds to the right, then [products] is higher than [reactants], and $K_{\mathrm{c}}>1$.

SOLUTION (a) The conjugate pairs are $\mathrm{H}_{2} \mathrm{PO}_{4}^{-} / \mathrm{HPO}_{4}{ }^{2-}$ and $\mathrm{NH}_{4}{ }^{+} / \mathrm{NH}_{3} \cdot \mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}$is higher on the list of acids, so it is stronger than $\mathrm{NH}_{4}{ }^{+}$; and $\mathrm{NH}_{3}$ is lower on the list of bases, so it is stronger than $\mathrm{HPO}_{4}{ }^{2-}$. Therefore,

$$
\begin{gathered}
\mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q)+\mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{NH}_{4}^{+}(a q)+\mathrm{HPO}_{4}^{2-}(a q) \\
\text { stronger acid }+ \text { stronger base } \longrightarrow \text { weaker acid }+ \text { weaker base }
\end{gathered}
$$

The net direction is right, so $K_{\mathrm{c}}>1$.
(b) The conjugate pairs are $\mathrm{H}_{2} \mathrm{O} / \mathrm{OH}^{-}$and $\mathrm{H}_{2} \mathrm{~S} / \mathrm{HS}^{-} . \mathrm{H}_{2} \mathrm{~S}$ is higher on the list of acids, and $\mathrm{OH}^{-}$is lower on the list of bases. Thus, we have

$$
\left.\begin{array}{rl}
\mathrm{H}_{2} \mathrm{O}(l) & +\mathrm{HS}^{-}(a q) \rightleftharpoons \mathrm{OH}^{-}(a q)
\end{array}\right)+\mathrm{H}_{2} \mathrm{~S}(a q), ~ 子 \text { stronger base }+ \text { stronger acid }
$$

The net direction is to the left, so $K_{\mathrm{c}}<1$.
FOLLOW-UP PROBLEM 18.5 Explain with balanced equations, in which you show the net direction of the reaction, each of the following observations:
(a) You smell ammonia when $\mathrm{NH}_{3}$ dissolves in water.
(b) The odor goes away when you add an excess of HCl to the solution in part (a).
(c) The odor returns when you add an excess of NaOH to the solution in part (b).

Figure 18.9 Strengths of conjugate acid-base pairs. The stronger the acid is, the weaker its conjugate base. The strongest acid appears at top left and the strongest base at bottom right. When an acid reacts with a base farther down the list, the reaction proceeds to the right ( $K_{c}>1$ ).

## SAMPLE PROBLEM 18.6 Using Molecular Scenes to Predict the Net Direction of an Acid-Base Reaction

PROBLEM Given that a 0.10 M solution of HX (blue and green) has a pH of 2.88 and a 0.10 M solution of HY (blue and orange) has a pH of 3.52 , which scene best represents the equilibrium mixture after equimolar solutions of HX and $\mathrm{Y}^{-}$(orange) are mixed?

PLAN A stronger acid and base yield a weaker acid and base, so we have to determine the relative acid strengths of HX and HY in order to choose the correct molecular scene. The concentrations of the acid solutions are equal, so we can pick the stronger acid directly from the pH values of the two solutions. The stronger acid will react to a greater extent, so fewer molecules of it will be in the scene than molecules of the weaker acid.
SOLUTION The HX solution has a lower pH (2.88) than the HY solution (3.52), so we know right away that HX is the stronger acid and $\mathrm{Y}^{-}$is the stronger base. Therefore, the reaction of HX and $\mathrm{Y}^{-}$has a $K_{\mathrm{c}}>1$, which means the equilibrium mixture will have more HY than HX. Scene 1 has equal numbers of HX and HY, which would occur if the acids were of equal strength, and scene 2 shows fewer HY than HX, which would occur if HY were stronger. Therefore, only scene 3 is consistent with the relative acid strengths.
FOLLOW-UP PROBLEM 18.6 The following scene represents the reaction mixture after 0.10 M solutions of HA (blue and red) and $\mathrm{B}^{-}$(black) react according to

$$
\mathrm{HA}(a q)+\mathrm{B}^{-}(a q) \rightleftharpoons \mathrm{A}^{-}(a q)+\mathrm{HB}(a q)
$$

and the reaction reaches equilibrium. Does the reaction have a $K_{\mathrm{c}}$ that is $>1$ or $<1$ ?

## Section Summary

The Brønsted-Lowry acid-base definition does not require that bases contain OH or that acid-base reactions occur in aqueous solution. - An acid is a species that donates a proton and a base is one that accepts it. • An acid and a base act together in proton transfer. When an acid donates a proton, it becomes the conjugate base; when a base accepts a proton, it becomes the conjugate acid. In an acid-base reaction, acids and bases form their conjugates. A stronger acid has a weaker conjugate base, and vice versa. - An acid-base reaction proceeds in the net direction in which a stronger acid and base form a weaker base and acid.

### 18.4 SOLVING PROBLEMS INVOLVING WEAK-ACID EQUILIBRIA

Just as you saw in Chapter 17 for equilibrium problems in general, there are two types of equilibrium problems involving weak acids and their conjugate bases:

1. Given equilibrium concentrations, find $K_{\mathrm{a}}$.
2. Given $K_{\mathrm{a}}$ and some concentration information, find the other equilibrium concentrations.

For all of these problems, we'll apply the same problem-solving approach, notation system, and assumptions:

- The problem-solving approach. As always, start with what is given in the problem statement and move logically toward what you want to find. Make a habit of applying the following steps:

1. Write the balanced equation and $K_{\mathrm{a}}$ expression; these tell you what to find.
2. Define $x$ as the unknown change in concentration that occurs during the reaction. Frequently, $x=[\mathrm{HA}]_{\text {dissoc }}$, the concentration of HA that dissociates, which, through the use of certain assumptions, also equals $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and [ $\mathrm{A}^{-}$] at equilibrium.
3. Construct a reaction table that incorporates the unknown.
4. Make assumptions (see below) that simplify the calculations, usually that $x$ is very small relative to the initial concentration.
5. Substitute the values into the $K_{\mathrm{a}}$ expression, and solve for $x$.
6. Check that the assumptions are justified. (Apply the $5 \%$ test that was first used in Sample Problem 17.10, p. 758.) If they are not justified, use the quadratic formula to find $x$.

- The notation system. As always, the molar concentration of each species is shown with brackets. A subscript refers to where the species comes from or when it occurs in the reaction process. For example, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from HA }}$ is the molar concentration of $\mathrm{H}_{3} \mathrm{O}^{+}$that comes from the dissociation of HA ; $[\mathrm{HA}]_{\text {init }}$ is the initial molar concentration of HA, that is, before the dissociation occurs; $[\mathrm{HA}]_{\text {dissoc }}$ is the molar concentration of HA that dissociates; and so forth. Recall that brackets with no subscript refer to the molar concentration of the species at equilibrium.

## Apago PDF Enhancer

- The assumptions. We make two assumptions to simplify the arithmetic:

1. The $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$from the autoionization of water is negligible. It is so much smaller than the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$from the dissociation of HA that we can neglect it in these problems:

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from HA }}+\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from } \mathrm{H}_{2} \mathrm{O}} \approx\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from HA }}
$$

Indeed, Le Châtelier's principle tells us that $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from HA }}$ decreases the extent of autoionization of water, so $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from } \mathrm{H}_{2} \mathrm{O}}$ in the HA solution is even less than $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$in pure water. Note that each molecule of HA that dissociates forms one $\mathrm{H}_{3} \mathrm{O}^{+}$and one $\mathrm{A}^{-}$, so $\left[\mathrm{A}^{-}\right]=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$.
2. A weak acid has a small $K_{\mathrm{a}}$. Therefore, it dissociates to such a small extent that we can neglect the change in its concentration to find its equilibrium concentration:

$$
[\mathrm{HA}]=[\mathrm{HA}]_{\text {init }}-[\mathrm{HA}]_{\text {dissoc }} \approx[\mathrm{HA}]_{\text {init }}
$$

## Finding $K_{\mathrm{a}}$ Given Concentrations

This type of problem involves finding $K_{\mathrm{a}}$ of a weak acid from the concentration of one of the species in solution, usually $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$from a given pH :

$$
\begin{gathered}
\mathrm{HA}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \underset{\mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{A}^{-}(a q)}{\rightleftharpoons} \\
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}
\end{gathered}
$$

A common approach is to prepare an aqueous solution of HA and measure its pH . Because you prepared the solution, you know $[\mathrm{HA}]_{\text {init }}$. You can calculate $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$ from the measured pH and then determine $\left[\mathrm{A}^{-}\right]$and $[\mathrm{HA}]$ at equilibrium. Then, you substitute these values into the $K_{\mathrm{a}}$ expression and solve for $K_{\mathrm{a}}$. You'll see how to make the assumptions discussed above and go through the approach in Sample Problem 18.7.

Phenylalanine, one of the amino acids that make up aspartame, is metabolized to phenylacetic acid (model).

SAMPLE PROBLEM 18.7 Finding $K_{\mathrm{a}}$ of a Weak Acid from the Solution pH PROBLEM Phenylacetic acid $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CH}_{2} \mathrm{COOH}\right.$, simplified here to HPAc; see model) builds up in the blood of persons with phenylketonuria, an inherited disorder that, if untreated, causes mental retardation and death. A study of the acid shows that the pH of 0.12 M HPAc is 2.62 . What is the $K_{\mathrm{a}}$ of phenylacetic acid?
PLAN We are given $[\mathrm{HPAc}]_{\text {init }}(0.12 M)$ and the $\mathrm{pH}(2.62)$ and must find $K_{\mathrm{a}}$. We first write the equation for HPAc dissociation and the expression for $K_{\mathrm{a}}$ to see which values we need to find:

$$
\operatorname{HPAc}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{PAc}^{-}(a q) \quad K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{PAc}^{-}\right]}{[\mathrm{HPAc}]}
$$

- To find $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$: We know the pH , so we can find $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$. Because a pH of 2.62 is more than four pH units ( $10^{4}$-fold) lower than the pH of pure water itself $(\mathrm{pH}=7.0)$, we can assume that $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from HPAc }} \gg\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from } \mathrm{H}_{2} \mathrm{O} \text {. Therefore, }}$ $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from HPAc }}+\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from } \mathrm{H}_{2} \mathrm{O}} \approx\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from HPAc }} \approx\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$. Note that the initial $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$in the reaction table is zero.
- To find $\left[\mathrm{PAc}^{-}\right]$: Because each HPAc that dissociates forms one $\mathrm{H}_{3} \mathrm{O}^{+}$and one $\mathrm{PAc}^{-}$, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \approx\left[\mathrm{PAc}^{-}\right]$.
- To find [HPAc]: We know [HPAc] $]_{\text {init }}$. Because HPAc is a weak acid, we assume that very little dissociates, so $[\mathrm{HPAc}]_{\text {init }}-[\mathrm{HPAc}]_{\text {dissoc }}=[\mathrm{HPAc}] \approx[\mathrm{HPAc}]_{\text {init }}$.

We set up a reaction table, make the assumptions, substitute the equilibrium values, solve for $K_{\mathrm{a}}$, and then check the assumptions.
SOLUTION Calculating $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$:

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-\mathrm{pH}}=10^{-2.62}=2.4 \times 10^{-3} \mathrm{M}
$$

Setting up the reaction table, with $x=[\mathrm{HPAc}]_{\text {dissoc }}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from HPAc }}=\left[\mathrm{PAc}^{-}\right] \approx\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$:

| Concentration $(M)$ | $\mathbf{H P A c}(a q)$ | + | $\mathbf{H}_{\mathbf{2}} \mathbf{O}(l)$ | $\rightleftharpoons$ | $\mathbf{H}_{3} \mathbf{O}^{+}(a q)$ | + |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{P A c}^{-}(a q)$ |  |  |  |  |  |  |
| Initial | 0.12 | - |  | 0 | 0 |  |
| Change | $-x$ | - |  | $+x$ | $+x$ |  |
| Equilibrium | $0.12-x$ | - |  | $x$ | $x$ |  |

Making the assumptions:

1. The calculated $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left(2.4 \times 10^{-3} \mathrm{M}\right) \gg\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from } \mathrm{H}_{2} \mathrm{O}}$, so we assume that $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$ $\approx\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from HPAc }}=x$ (the change in [HPAc]).
2. HPAc is a weak acid, so we assume that [HPAc] $=0.12 M-x \approx 0.12 M$.

Solving for the equilibrium concentrations:

$$
\begin{gathered}
x \approx\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\left[\mathrm{PAc}^{-}\right]=2.4 \times 10^{-3} M \\
{[\mathrm{HPAc}]=0.12 M-x=0.12 M-\left(2.4 \times 10^{-3} M\right) \approx 0.12 M(\text { to } 2 \mathrm{sf})}
\end{gathered}
$$

Substituting these values into $K_{\mathrm{a}}$ :

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{PAc}^{-}\right]}{[\mathrm{HPAc}]} \approx \frac{\left(2.4 \times 10^{-3}\right)\left(2.4 \times 10^{-3}\right)}{0.12}=4.8 \times 10^{-5}
$$

Checking the assumptions by finding the percent error in concentration:

1. For $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from } \mathrm{H}_{2} \mathrm{O}}$ : $\frac{1 \times 10^{-7} \mathrm{M}}{2.4 \times 10^{-3} \mathrm{M}} \times 100=4 \times 10^{-3} \%(<5 \%$; assumption is justified).
2. For $[\mathrm{HPAc}]_{\text {dissoc }}: \frac{2.4 \times 10^{-3} M}{0.12 M} \times 100=2.0 \%(<5 \%$; assumption is justified).

CHECK The $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$makes sense: pH 2.62 should give $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right.$] between $10^{-2}$ and $10^{-3} \mathrm{M}$. The $K_{\mathrm{a}}$ calculation also seems in the correct range: $\left(10^{-3}\right)^{2} / 10^{-1}=10^{-5}$, and this value seems reasonable for a weak acid.
COMMENT $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from } \mathrm{H}_{2} \mathrm{O}}$ is so small relative to $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from HA }}$ that, as shown in this problem, we will enter it as zero in all subsequent reaction tables.
FOLLOW-UP PROBLEM 18.7 The conjugate acid of ammonia is $\mathrm{NH}_{4}{ }^{+}$, a weak acid. If a 0.2 M NH 44 solution has a pH of 5.0 , what is the $K_{\mathrm{a}}$ of $\mathrm{NH}_{4}^{+}$?

## Finding Concentrations Given $K_{\mathrm{a}}$

The second type of equilibrium problem involving weak acids gives some concentration data and the $K_{\mathrm{a}}$ value and asks for the equilibrium concentration of some component. Such problems are very similar to those we solved in Chapter 17 in which a substance with a given initial concentration reacted to an unknown extent (see Sample Problems 17.9 to 17.11).

## SAMPLE PROBLEM 18.8 Determining Concentrations from $K_{\mathrm{a}}$ and Initial [HA]

PROBLEM Propanoic acid $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{COOH}\right.$, which we simplify as HPr$)$ is a carboxylic acid whose salts are used to retard mold growth in foods. What is the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$of 0.10 M HPr $\left(K_{\mathrm{a}}=1.3 \times 10^{-5}\right)$ ?
PLAN We know the initial concentration $(0.10 M)$ and $K_{\mathrm{a}}\left(1.3 \times 10^{-5}\right)$ of HPr , and we need to find $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$. First, we write the balanced equation and the expression for $K_{\mathrm{a}}$ :

$$
\mathrm{HPr}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\operatorname{Pr}^{-}(a q) \quad K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{Pr}^{-}\right]}{[\mathrm{HPr}]}=1.3 \times 10^{-5}
$$

We know $[\mathrm{HPr}]_{\text {init }}$ but not $[\mathrm{HPr}]$. If we let $x=[\mathrm{HPr}]_{\text {dissoc }}, x$ is also $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from }}$ HPr and [ $\mathrm{Pr}^{-}$] because each HPr that dissociates yields one $\mathrm{H}_{3} \mathrm{O}^{+}$and one $\mathrm{Pr}^{-}$. With this information, we can set up a reaction table. In solving for $x$, we assume that, because HPr has a small $K_{\mathrm{a}}$, it dissociates very little; therefore, $[\mathrm{HPr}]_{\text {init }}-x=[\mathrm{HPr}] \approx[\mathrm{HPr}]_{\text {init }}$. After we find $x$, we check the assumption.
SOLUTION Setting up a reaction table, with $x=[\mathrm{HPr}]_{\text {dissoc }}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from HPr }}=\left[\mathrm{Pr}^{-}\right]=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$:

| Concentration $(M)$ | $\mathbf{H P r}(\mathbf{a q})$ | + | $\mathrm{H}_{2} \mathbf{O}(\mathbf{l})$ | $\rightleftharpoons$ | $\mathrm{H}_{3} \mathbf{O}^{+}(a q)$ | + |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{Pr}^{-}(\mathrm{aq})$ |  |  |  |  |  |  |
| Initial | 0.10 | - |  | 0 | 0 |  |
| Change | $-x$ | - |  | $+x$ | $+x$ |  |
| Equilibrium | $0.10-x$ | - |  | $x$ | $x$ |  |

Making the assumption: $K_{\mathrm{a}}$ is small, so $x$ is small compared with $[\mathrm{HPr}]_{\mathrm{init}}$; therefore, $0.10 M-x \approx 0.10 M$. Substituting into the $K_{\mathrm{a}}$ expression and solving for $x$ :

$$
\begin{aligned}
K_{\mathrm{a}} & =\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{Pr}^{-}\right]}{[\mathrm{HPr}]}=1.3 \times 10^{-5} \approx \frac{(x)(x)}{0.10} \\
x & \approx \sqrt{(0.10)\left(1.3 \times 10^{-5}\right)} \\
& =1.1 \times 10^{-3} M=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]
\end{aligned}
$$

Checking the assumption:
For $[\mathrm{HPr}]_{\text {dissoc }}: \frac{1.1 \times 10^{-3} M}{0.10 M} \times 100=1.1 \%(<5 \%$; assumption is justified $)$.
CHECK The $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$seems reasonable for a dilute solution of a weak acid with a moderate $K_{\mathrm{a}}$. By reversing the calculation, we can check the math: $\left(1.1 \times 10^{-3}\right)^{2} / 0.10=$ $1.2 \times 10^{-5}$, which is within rounding of the given $K_{\mathrm{a}}$.
COMMENT We assume the concentration of HA that dissociates $\left([H A]_{\text {dissoc }}=x\right)$ can be neglected if $K_{\mathrm{a}}$ is small. But that also depends on $[\mathrm{HA}]_{\text {init }}$. We'll use the same benchmark introduced in Sample Problem 17.10 (see Comment) to see if the assumption is justified:

- If $\frac{[\mathrm{HA}]_{\text {init }}}{K_{\mathrm{a}}}>400$, the assumption is justified: neglecting $x$ introduces an error $<5 \%$.
- If $\frac{[\mathrm{HA}]_{\text {init }}}{K_{\mathrm{a}}}<400$, the assumption is not justified; neglecting $x$ introduces an error $>5 \%$, so we solve a quadratic equation to find $x$.
The latter situation occurs in the follow-up problem.
FOLLOW-UP PROBLEM 18.8 Cyanic acid (HOCN) is an extremely acrid, unstable substance. What is the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and pH of $0.10 \mathrm{M} \mathrm{HOCN}\left(K_{\mathrm{a}}=3.5 \times 10^{-4}\right)$ ?

## The Effect of Concentration on the Extent of Acid Dissociation

If we repeat the calculation in Sample Problem 18.8, but start with a lower [HPr], we observe a very interesting fact about the extent of dissociation of a weak acid. Suppose the initial concentration of HPr is one-tenth as much, 0.010 M rather than 0.10 M . After filling in the reaction table and making the same assumptions, we find that

$$
x=[\mathrm{HPr}]_{\text {dissoc }}=3.6 \times 10^{-4} \mathrm{M}
$$

Now, let's compare the percentages of HPr molecules dissociated at the two different initial acid concentrations, using the relationship

$$
\begin{equation*}
\text { Percent HA dissociated }=\frac{[\mathrm{HA}]_{\text {dissoc }}}{[\mathrm{HA}]_{\text {init }}} \times 100 \tag{18.5}
\end{equation*}
$$

Case 1: $[\mathrm{HPr}]_{\text {nitit }}=0.10 \mathrm{M}$

$$
\text { Percent dissociated }=\frac{1.1 \times 10^{-3} \mathrm{M}}{1.0 \times 10^{-1} \mathrm{M}} \times 100=1.1 \%
$$

Case 2: $[\mathrm{HPr}]_{\text {init }}=0.010 \mathrm{M}$

$$
\text { Percent dissociated }=\frac{3.6 \times 10^{-4} \mathrm{M}}{1.0 \times 10^{-2} \mathrm{M}} \times 100=3.6 \%
$$

As the initial acid concentration decreases, the percent dissociation of the acid increases. Don't confuse the concentration of HA dissociated with the percent HA dissociated. The concentration, $[\mathrm{HA}]_{\text {dissoc }}$, is lower in the diluted HA solution because the actual number of dissociated HA molecules is smaller. It is the fraction (or the percent) of dissociated HA molecules that increases with dilution.

This phenomenon is analogous to a change in container volume (pressure) for gases at equilibrium (see the discussion in Section 17.6). In that situation, an
 the case of HA dissociation, the available volume increases as solvent is added and the solution is diluted; this increase in volume shifts the equilibrium position to favor more moles of ions. Sample Problem 18.9 uses molecular scenes to highlight this idea. (Note that, in order to depict the scenes practically, the acid has a much higher percent dissociation than actually occurs for any weak acid.)

SAMPLE PROBLEM 18.9 Using Molecular Scenes to Determine the Extent of HA Dissociation
PROBLEM A 0.15 M solution of acid HA (blue and green) is $33 \%$ dissociated. Which scene represents a sample of that solution after it is diluted with water?

PLAN We are given the percent dissociation of the original HA solution (33\%), and we know that the percent dissociation increases as the acid is diluted. Thus, we calculate the percent dissociation of each diluted sample and see which is greater than $33 \%$. To determine percent dissociation, we apply Equation 18.5 , with $\mathrm{HA}_{\text {dissoc }}$ equal to the number of $\mathrm{H}_{3} \mathrm{O}^{+}$(or $\mathrm{A}^{-}$) and $\mathrm{HA}_{\text {total }}$ equal to the number of HA plus the number of $\mathrm{H}_{3} \mathrm{O}^{+}$(or $\mathrm{A}^{-}$). SOLUTION Calculating the percent dissociation of each diluted solution with Equation 18.5:
Solution 1. Percent dissociated $=4 /(5+4) \times 100=44 \%$
Solution 2. Percent dissociated $=2 /(7+2) \times 100=22 \%$
Solution 3. Percent dissociated $=3 /(6+3) \times 100=33 \%$
Therefore, scene 1 represents the diluted solution.

CHECK Let's confirm our choice by examining the other scenes: in scene 2, HA is less dissociated than originally, so that scene must represent a more concentrated HA solution; scene 3 represents another solution with the same percent dissociation as the original.
FOLLOW-UP PROBLEM 18.9 The scene in the margin represents a sample of a weak acid HB (purple) dissolved in water. Draw a scene that represents the same volume after the solution has been diluted with water.

## The Behavior of Polyprotic Acids

Acids with more than one ionizable proton are polyprotic acids. In a solution of a polyprotic acid, one proton at a time dissociates from the acid molecule, and each dissociation step has a different $K_{\mathrm{a}}$. For example, phosphoric acid is a triprotic acid (three ionizable protons), so it has three $K_{\mathrm{a}}$ values:

$$
\begin{gathered}
\mathrm{H}_{3} \mathrm{PO}_{4}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \\
K_{\mathrm{a} 1}=\frac{\left[\mathrm{H}_{2} \mathrm{PO}_{4}^{-}\right]\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}{\left[\mathrm{H}_{3} \mathrm{PO}_{4}\right]}=7.2 \times 10^{-3} \\
\mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HPO}_{4}{ }^{2-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \\
K_{\mathrm{a} 2}=\frac{\left[\mathrm{HPO}_{4}{ }^{2-}\right]\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}{\left[\mathrm{H}_{2} \mathrm{PO}_{4}^{-}\right]}=6.3 \times 10^{-8} \\
\mathrm{HPO}_{4}{ }^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{PO}_{4}^{3-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \\
K_{\mathrm{a} 3}=\frac{\left[\mathrm{PO}_{4}^{3-}\right]\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}{\left[\mathrm{HPO}_{4}{ }^{2-}\right]}=4.2 \times 10^{-13}
\end{gathered}
$$

As you can see from the relative $K_{\mathrm{a}}$ values, $\mathrm{H}_{3} \mathrm{PO}_{4}$ is a much stronger acid than $\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}$, which is much stronger than $\mathrm{HPO}_{4}{ }^{2-}$. Table 18.5 lists some common polyprotic acids and their $K_{\mathrm{a}}$ values. (MoreGrelisted inAppendix C. ${ }^{\text {P Noficethat, }}$ in every case, the first proton comes off to a much greater extent than the second and, where applicable, the second does to a much greater extent than the third:

$$
K_{\mathrm{a} 1}>K_{\mathrm{a} 2}>K_{\mathrm{a} 3}
$$

Table 18.5 Successive $K_{\mathrm{a}}$ Values for Some Polyprotic Acids at $25^{\circ} \mathrm{C}$

| Name (Formula) | Lewis Structure* | $K_{\text {a } 1}$ | $K_{\text {a } 2}$ | $K_{\text {a3 }}$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Oxalic acid ( $\left.\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right)$ |  | $5.6 \times 10^{-2}$ | $5.4 \times 10^{-5}$ |  |  |
| Sulfurous acid ( $\left.\mathrm{H}_{2} \mathrm{SO}_{3}\right)$ |  | $1.4 \times 10^{-2}$ | $6.5 \times 10^{-8}$ |  |  |
| Phosphoric acid $\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)$ |  | $7.2 \times 10^{-3}$ | $6.3 \times 10^{-8}$ | $4.2 \times 10^{-13}$ | 픈 |
| Arsenic acid ( $\mathrm{H}_{3} \mathrm{AsO}_{4}$ ) |  | $6 \times 10^{-3}$ | $1.1 \times 10^{-7}$ | $3 \times 10^{-12}$ | 告 |
| Carbonic acid ( $\mathrm{H}_{2} \mathrm{CO}_{3}$ ) |  | $4.5 \times 10^{-7}$ | $4.7 \times 10^{-11}$ |  |  |
| Hydrosulfuric acid ( $\mathrm{H}_{2} \mathrm{~S}$ ) | H-S. | $9 \times 10^{-8}$ | $1 \times 10^{-17}$ |  |  |

This trend makes sense: it is more difficult for an $\mathrm{H}^{+}$ion to leave a singly charged anion (such as $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}$) than to leave a neutral molecule (such as $\mathrm{H}_{3} \mathrm{PO}_{4}$ ), and more difficult still for it to leave a doubly charged anion $\left(\mathrm{HPO}_{4}{ }^{2-}\right)$. Successive acid-dissociation constants typically differ by several orders of magnitude. This fact greatly simplifies pH calculations involving polyprotic acids because we can usually neglect the $\mathrm{H}_{3} \mathrm{O}^{+}$coming from the subsequent dissociations.

## SAMPLE PROBLEM 18.10 Calculating Equilibrium Concentrations for a Polyprotic Acid

PROBLEM Ascorbic acid $\left(\mathrm{H}_{2} \mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{6} ; \mathrm{H}_{2}\right.$ Asc for this problem), known as vitamin C, is a diprotic acid ( $K_{\mathrm{a} 1}=1.0 \times 10^{-5}$ and $K_{\mathrm{a} 2}=5 \times 10^{-12}$ ) found in citrus fruit. Calculate [ $\left.\mathrm{H}_{2} \mathrm{Asc}\right],\left[\mathrm{HAsc}^{-}\right],\left[\mathrm{Asc}^{2-}\right]$, and the pH of $0.050 M \mathrm{H}_{2}$ Asc.
PLAN We know the initial concentration $(0.050 \mathrm{M})$ and both $K_{\mathrm{a}}$ 's for $\mathrm{H}_{2} \mathrm{Asc}$, and we have to calculate the equilibrium concentrations of all species and convert $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$to pH . We first write the equations and $K_{\mathrm{a}}$ expressions:

$$
\begin{aligned}
\mathrm{H}_{2} \mathrm{Asc}(a q) & +\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HAsc}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \\
K_{\mathrm{a} 1} & =\frac{\left[\mathrm{HAsc}^{-}\right]\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}{\left[\mathrm{H}_{2} \mathrm{Asc}\right]}=1.0 \times 10^{-5} \\
\mathrm{HAsc}^{-}(a q) & +\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{Asc}^{2-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \\
K_{\mathrm{a} 2} & =\frac{\left[\mathrm{Asc}^{2-}\right]\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}{\left[\mathrm{HAsc}^{-}\right]}=5 \times 10^{-12}
\end{aligned}
$$

Then we assume the following:

1. Because $K_{\mathrm{a} 1} \gg K_{\mathrm{a} 2}$, dissociation of the first proton produces almost all the $\mathrm{H}_{3} \mathrm{O}^{+}$: $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from } \mathrm{H}_{2} \mathrm{Asc}} \gg\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from HAsc }}$.
2. Because $K_{\mathrm{a} 1}$ is small, the amount of $\mathrm{H}_{2}$ Asc that dissociates can be neglected relative to the initial concentration: $\left[\mathrm{H}_{2} \mathrm{Asc}\right]_{\text {init }} \approx\left[\mathrm{H}_{2} \mathrm{Asc}\right]$.
We set up a reaction table for the first dissociation, with $x$ equal to the concentration of $\mathrm{H}_{2}$ Asc that dissociates, and then solve for $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and $\left[\mathrm{HAsc}^{-}\right.$]. Because the second dissociation occurs to a much lesser extent than the first, we can substitute values from the first dissociation directly to find $\left[\mathrm{Asc}^{2-}\right]$ of the second.
SOLUTION Setting up a reaction table with $x=\left[\mathrm{H}_{2} \mathrm{Asc}\right]_{\text {dissoc }}=\left[\mathrm{HAsc}^{-}\right] \approx\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$:

| Concentration (M) | $\mathrm{H}_{2} \mathrm{Asc}(\mathrm{aq})$ | + | $\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ | $\rightleftharpoons$ | $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ | $+$ | $\mathrm{HAsc}^{-}(\mathrm{aq})$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Initial | 0.050 |  | - |  | 0 |  | 0 |
| Change | - $x$ |  | - |  | + $x$ |  | + $x$ |
| Equilibrium | $0.050-x$ |  | - |  | $x$ |  | $x$ |

Making the assumptions:

1. Because $K_{\mathrm{a} 2} \ll K_{\mathrm{a} 1},\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from HAsc }}{ }^{-} \ll\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from } \mathrm{H}_{2} \mathrm{Asc}}$. Therefore,

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\mathrm{from} \mathrm{H}_{2} \mathrm{Asc}} \approx\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]
$$

2. Because $K_{\mathrm{a} 1}$ is small, $\left[\mathrm{H}_{2} \mathrm{Asc}\right]_{\text {init }}-x=\left[\mathrm{H}_{2} \mathrm{Asc}\right] \approx\left[\mathrm{H}_{2} \mathrm{Asc}\right]_{\text {init }}$. Thus,

$$
\left[\mathrm{H}_{2} \mathrm{Asc}\right]=0.050 \mathrm{M}-x \approx 0.050 \mathrm{M}
$$

Substituting into the expression for $K_{\mathrm{a} 1}$ and solving for $x$ :

$$
\begin{aligned}
K_{\mathrm{a} 1} & =\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{HAsc}^{-}\right]}{\left[\mathrm{H}_{2} \mathrm{Asc}\right]}=1.0 \times 10^{-5} \approx \frac{x^{2}}{0.050} \\
x & =\left[\mathrm{HAsc}^{-}\right] \approx\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \approx 7.1 \times 10^{-4} M \\
\mathrm{pH} & =-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=-\log \left(7.1 \times 10^{-4}\right)=3.15
\end{aligned}
$$

Checking the assumptions:

1. $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from } \mathrm{HAsc}^{-}} \ll\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from } \mathrm{H}_{2} \mathrm{Asc}}$ : For any second dissociation that does occur, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from HAsc }} \approx \sqrt{\left[\mathrm{HAsc}^{-}\right]\left(K_{\mathrm{a} 2}\right)}=\sqrt{\left(7.1 \times 10^{-4}\right)\left(5 \times 10^{-12}\right)}=6 \times 10^{-8} \mathrm{M}$
This is even less than $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from } \mathrm{H}_{2} \mathrm{O}}$, so the assumption is justified.
2. $\left[\mathrm{H}_{2} \mathrm{Asc}\right]_{\text {dissoc }} \ll\left[\mathrm{H}_{2} \mathrm{Asc}\right]_{\text {init }}: \frac{7.1 \times 10^{-4} M}{0.050 M} \times 100=1.4 \%(<5 \%$; assumption is justified $)$.

Also, from the Comment in Sample Problem 18.8, note that

$$
\frac{\left[\mathrm{H}_{2} \mathrm{Asc}\right]_{\text {init }}}{K_{\mathrm{a} 1}}=\frac{0.050}{1.0 \times 10^{-5}}=5000>400
$$

Calculating [Asc ${ }^{2-}$ ]:

$$
\begin{aligned}
K_{\mathrm{a} 2}= & \frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{Asc}^{2-}\right]}{\left[\mathrm{HAsc}^{-}\right]} \text {and }\left[\mathrm{Asc}^{2-}\right]=\frac{\left(K_{\mathrm{a} 2}\right)\left[\mathrm{HAsc}^{-}\right]}{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]} \\
& {\left[\mathrm{Asc}^{2-}\right]=\frac{\left(5 \times 10^{-12}\right)\left(7.1 \times 10^{-4}\right)}{7.1 \times 10^{-4}}=5 \times 10^{-12} \mathrm{M} }
\end{aligned}
$$

CHECK $K_{\mathrm{a} 1} \gg K_{\mathrm{a} 2}$, so it makes sense that $\left[\mathrm{HAsc}^{-}\right] \gg\left[\mathrm{Asc}^{2-}\right]$ because $\mathrm{Asc}^{2-}$ is produced only in the second (much weaker) dissociation. Both $K_{\mathrm{a}}$ 's are small, so all concentrations except $\left[\mathrm{H}_{2} \mathrm{Asc}\right]$ should be much lower than the original 0.050 M .
FOLLOW-UP PROBLEM 18.10 Oxalic acid ( $\mathrm{HOOC}-\mathrm{COOH}$, or $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$ ) is the simplest diprotic carboxylic acid. Its commercial uses include bleaching straw and leather and removing rust and ink stains. Calculate $\left[\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right],\left[\mathrm{HC}_{2} \mathrm{O}_{4}{ }^{-}\right],\left[\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}\right]$, and the pH of a $0.150 M \mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$ solution. Use $K_{\mathrm{a}}$ values from Appendix C.

## Section Summary

Two common types of weak-acid equilibrium problems involve finding $K_{\mathrm{a}}$ from a concentration and finding a concentration from $K_{\mathrm{a}}$. - We summarize the information in a reaction table, and we simplify the arithmetic by assuming (1) $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from }} \mathrm{H}_{2} \mathrm{O}$ is so small relative to $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from }}$ HA that it can be neglected, and (2) weak acids dissociate so little that $[H A]_{\text {init }} \approx[H A]$ at equilibrium. - The fraction of weak acid molecules that dissociates is greater in a more dilute solution, even though the total $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$is less. - Polyprotic acids have more than one ionizable proton, but we assume that the first dissociation provides virtually all the $\mathrm{H}_{3} \mathrm{O}^{+}$.

### 18.5 WEAK BASES AND THEIR RELATION TO WEAK ACIDS

By focusing on where the proton comes from and goes to, the Brønsted-Lowry concept expands the definition of a base to encompass a host of species that the Arrhenius definition excludes: a base is any species that accepts a proton; to do so, the base must have a lone electron pair. (The lone electron pair also plays the central role in the Lewis acid-base definition, as you'll see later in this chapter.)

Now let's examine the equilibrium system of a weak base and focus, as we did for weak acids, on the base (B) dissolving in water. When B dissolves, it accepts a proton from $\mathrm{H}_{2} \mathrm{O}$, which acts as an acid, leaving behind an $\mathrm{OH}^{-}$ion:

$$
\mathrm{B}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{BH}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

This general reaction for a base in water is described by the equilibrium expression

$$
K_{\mathrm{c}}=\frac{\left[\mathrm{BH}^{+}\right]\left[\mathrm{OH}^{-}\right]}{[\mathrm{B}]\left[\mathrm{H}_{2} \mathrm{O}\right]}
$$

Based on our earlier reasoning that $\left[\mathrm{H}_{2} \mathrm{O}\right]$ is treated as a constant in aqueous reactions, we incorporate $\left[\mathrm{H}_{2} \mathrm{O}\right]$ in the value of $K_{\mathrm{c}}$ and obtain the base-dissociation constant (or base-ionization constant), $\boldsymbol{K}_{\mathbf{b}}$ :

$$
\begin{equation*}
K_{\mathrm{b}}=\frac{\left[\mathrm{BH}^{+}\right]\left[\mathrm{OH}^{-}\right]}{[\mathrm{B}]} \tag{18.6}
\end{equation*}
$$

Despite the name "base-dissociation constant," no base dissociates in the process, as you can see from the reaction.

As in the relation between $\mathrm{p} K_{\mathrm{a}}$ and $K_{\mathrm{a}}$, we know that $\mathrm{p} K_{\mathrm{b}}$, the negative logarithm of the base-dissociation constant, decreases with increasing $K_{\mathrm{b}}$ (that is, increasing base strength). In aqueous solution, the two large classes of weak bases are ammonia and the amines, and the anions of weak acids.

## Molecules as Weak Bases: Ammonia and the Amines

Ammonia is the simplest nitrogen-containing compound that acts as a weak base in water:

$$
\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q) \quad K_{\mathrm{b}}=1.76 \times 10^{-5}\left(\text { at } 25^{\circ} \mathrm{C}\right)
$$

Despite labels on reagent bottles that read "ammonium hydroxide," an aqueous solution of ammonia consists largely of unprotonated $\mathrm{NH}_{3}$ molecules, as its small $K_{\mathrm{b}}$ indicates. In a $1.0 \mathrm{NH}_{3}$ solution, for example, $\left[\mathrm{OH}^{-}\right]=\left[\mathrm{NH}_{4}{ }^{+}\right]=$ $4.2 \times 10^{-3} M$, so about $99.58 \%$ of the $\mathrm{NH}_{3}$ is not ionized. Table 18.6 shows the $K_{\mathrm{b}}$ values for a few common molecular bases. (A more extensive list appears in Appendix C.)

## Table $18.6 K_{\mathrm{b}}$ Values for Some Molecular (Amine) Bases at $25^{\circ} \mathrm{C}$

| Name (Formula) | Lewis Structure* | $K_{\text {b }}$ |  |
| :---: | :---: | :---: | :---: |
| Diethylamine [ $\left.\left(\mathrm{CH}_{3} \mathrm{CH}_{2}\right)_{2} \mathrm{NH}\right]$ | ] | $8.6 \times 10^{-4}$ |  |
| Dimethylamine $\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}\right]$ |  | $5.9 \times 10^{-4}$ |  |
| Methylamine $\left(\mathrm{CH}_{3} \mathrm{NH}_{2}\right)$ <br> Apago PDF |  | $4.4 \times 10^{-4}$ |  |
| Ammonia $\left(\mathrm{NH}_{3}\right)$ |  | $1.76 \times 10^{-5}$ |  |
| Pyridine ( $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}$ ) |  | $1.7 \times 10^{-9}$ |  |
| Aniline ( $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}$ ) |  | $4.0 \times 10^{-10}$ |  |

*Blue type indicates the basic nitrogen and its lone pair.

If one or more of the hydrogen atoms in ammonia is replaced by an organic group (designated as R ), an amine results: $\mathrm{RNH}_{2}, \mathrm{R}_{2} \mathrm{NH}$, or $\mathrm{R}_{3} \mathrm{~N}$ (Section 15.4; see Figure 15.15). The key structural feature of these organic compounds, as in all Brønsted-Lowry bases, is a lone pair of electrons that can bind the proton donated by the acid. Figure 18.10 depicts this process for methylamine, the simplest amine.

Figure 18.10 Abstraction of a proton from water by methylamine. The amines are organic derivatives of ammonia. Methylamine, the simplest amine, acts as a base in water by accepting a proton, thereby increasing $\left[\mathrm{OH}^{-}\right]$.

To find the pH of a solution of a molecular weak base, we use an approach very similar to that for a weak acid: write the equilibrium expression, set up a reaction table to find $[\text { base }]_{\text {reacting }}$, make the usual assumptions, and then solve for $\left[\mathrm{OH}^{-}\right]$. The main difference is that we must convert $\left[\mathrm{OH}^{-}\right]$to $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$in order to calculate pH .

## SAMPLE PROBLEM 18.11 Determining pH from $K_{\mathrm{b}}$ and Initial [B]

PROBLEM Dimethylamine, $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}$ (see margin), a key intermediate in detergent manufacture, has a $K_{\mathrm{b}}$ of $5.9 \times 10^{-4}$. What is the pH of $1.5 \mathrm{M}\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}$ ?
PLAN We know the initial concentration $(1.5 M)$ and $K_{\mathrm{b}}\left(5.9 \times 10^{-4}\right)$ of $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}$ and have to find the pH . The amine reacts with water to form $\mathrm{OH}^{-}$, so we have to find $\left[\mathrm{OH}^{-}\right]$ and then calculate $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and pH . The balanced equation and $K_{\mathrm{b}}$ expression are

$$
\begin{gathered}
\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}_{2}^{+}(a q)+\mathrm{OH}^{-}(a q) \\
K_{\mathrm{b}}=\frac{\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}_{2}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}\right]}
\end{gathered}
$$

Because $K_{\mathrm{b}} \gg K_{\mathrm{w}}$, the $\left[\mathrm{OH}^{-}\right]$from the autoionization of water is negligible, and we disregard it. Therefore,

$$
\left[\mathrm{OH}^{-}\right]_{\text {from base }}=\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}_{2}^{+}\right]=\left[\mathrm{OH}^{-}\right]
$$

Because $K_{\mathrm{b}}$ is small, we assume that the amount of amine reacting is small, so

$$
\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}\right]_{\text {init }}-\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}\right]_{\text {reacting }}=\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}\right] \approx\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}\right]_{\text {init }}
$$

As usual, we set up a reaction table, make the assumption, and solve for $x$. Then we check the assumption and convert $\left[\mathrm{OH}^{-}\right]$to $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$using $K_{\mathrm{w}}$; finally, we calculate pH .
SOLUTION Setting up the reaction table, with

$$
x=\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}\right]_{\text {reacting }}=\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}_{2}^{+}\right]=\left[\mathrm{OH}^{-}\right]
$$

| Concentration $(M)$ | $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}(a q)$ | $+\mathrm{H}_{2} \mathrm{O}(l)$ | $\rightleftharpoons$ | $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}_{2}{ }^{+}(a q)$ | $+\mathrm{OH}^{-}(a q)$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Initial | 1.5 | - |  | 0 | 0 |
| Change | $-x$ | - |  | $+x$ | $+x$ |
| Equilibrium | $1.5-x$ | - |  | $x$ | $x$ |

Making the assumption:
$K_{\mathrm{b}}$ is small, so $\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}\right]_{\text {init }} \approx\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}\right]$; thus, $1.5 \mathrm{M}-x \approx 1.5 \mathrm{M}$.
Substituting into the $K_{\mathrm{b}}$ expression and solving for $x$ :

$$
\begin{aligned}
K_{\mathrm{b}} & =\frac{\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}_{2}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}\right]}=5.9 \times 10^{-4} \approx \frac{x^{2}}{1.5} \\
x & =\left[\mathrm{OH}^{-}\right] \approx 3.0 \times 10^{-2} M
\end{aligned}
$$

Checking the assumption:

$$
\frac{3.0 \times 10^{-2} M}{1.5 M} \times 100=2.0 \%(<5 \% ; \text { assumption is justified })
$$

Note that the Comment in Sample Problem 18.8 applies to weak bases as well:

$$
\frac{[\mathrm{B}]_{\text {init }}}{K_{\mathrm{b}}}=\frac{1.5}{5.9 \times 10^{-4}}=2.5 \times 10^{3}>400
$$

Calculating pH :

$$
\begin{aligned}
{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] } & =\frac{K_{\mathrm{w}}}{\left[\mathrm{OH}^{-}\right]}=\frac{1.0 \times 10^{-14}}{3.0 \times 10^{-2}}=3.3 \times 10^{-13} \mathrm{M} \\
\mathrm{pH} & =-\log \left(3.3 \times 10^{-13}\right)=12.48
\end{aligned}
$$

CHECK The value of $x$ seems reasonable: $\sqrt{\left(\sim 6 \times 10^{-4}\right)(1.5)}=\sqrt{9 \times 10^{-4}}=3 \times 10^{-2}$. Because $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}$ is a weak base, the pH should be several pH units greater than 7 .
FOLLOW-UP PROBLEM 18.11 Pyridine $\left(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\right.$, see margin) serves as a solvent and base in organic syntheses. It has a $\mathrm{p} K_{\mathrm{b}}$ of 8.77 . What is the pH of 0.10 M pyridine?

Pyridine

## Anions of Weak Acids as Weak Bases

The other large group of Brønsted-Lowry bases consists of anions of weak acids:*

$$
\mathrm{A}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HA}(a q)+\mathrm{OH}^{-}(a q) \quad K_{\mathrm{b}}=\frac{[\mathrm{HA}]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{A}^{-}\right]}
$$

For example, $\mathrm{F}^{-}$, the anion of the weak acid HF , acts as a weak base:

$$
\mathrm{F}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HF}(a q)+\mathrm{OH}^{-}(a q) \quad K_{\mathrm{b}}=\frac{[\mathrm{HF}]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{F}^{-}\right]}
$$

Why is a solution of HA acidic and a solution of A ${ }^{-}$basic? Let's approach the question by examining the relative concentrations of species present in $1 M \mathrm{HF}$ and in 1 M NaF :

1. The acidity of HA (aq). Because HF is a weak acid, most of it is undissociated. The small fraction of HF that does dissociate yields small concentrations of $\mathrm{H}_{3} \mathrm{O}^{+}$and $\mathrm{F}^{-}$. The equilibrium position of the system lies far to the left:

$$
\mathrm{HF}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{F}^{-}(a q)
$$

Water molecules also contribute $\mathrm{H}_{3} \mathrm{O}^{+}$and $\mathrm{OH}^{-}$, but these concentrations are extremely small:

$$
2 \mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

Of all the species present- $\mathrm{HF}, \mathrm{H}_{2} \mathrm{O}, \mathrm{H}_{3} \mathrm{O}^{+}, \mathrm{F}^{-}$, and $\mathrm{OH}^{-}$-the two that can influence the acidity of the solution are $\mathrm{H}_{3} \mathrm{O}^{+}$, predominantly from HF , and $\mathrm{OH}^{-}$ from water. The solution is acidic because $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from } \mathrm{HF}} \gg\left[\mathrm{OH}^{-}\right]_{\text {from } \mathrm{H}_{2} \mathrm{O}}$.
2. The basicity of $A^{-}(a q)$. Now, consider the species present in 1 MNaF . The salt dissociates completely to yield a stoichiometric concentration of $\mathrm{F}^{-}$. The $\mathrm{Na}^{+}$ ion behaves as a spectator, and some $\mathrm{F}^{-}$reacts as a weak base to produce very small amounts of HF and $\mathrm{OH}^{-}$:

## Apago PDIGq) 玉Hzqu

As before, water dissociation contributes minute amounts of $\mathrm{H}_{3} \mathrm{O}^{+}$and $\mathrm{OH}^{-}$. Thus, in addition to the $\mathrm{Na}^{+}$ion, the species present are the same as in the HF solution: $\mathrm{HF}, \mathrm{H}_{2} \mathrm{O}, \mathrm{H}_{3} \mathrm{O}^{+}, \mathrm{F}^{-}$, and $\mathrm{OH}^{-}$. The two species that affect the acidity are $\mathrm{OH}^{-}$, predominantly from the $\mathrm{F}^{-}$reaction with water, and $\mathrm{H}_{3} \mathrm{O}^{+}$from water. In this case, $\left[\mathrm{OH}^{-}\right]_{\text {from } \mathrm{F}^{-}} \gg\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from } \mathrm{H}_{2} \mathrm{O}}$, so the solution is basic.

To summarize, the relative concentrations of $H A$ and $A^{-}$determine the acidity or basicity of the solution:

- In an HA solution, $[\mathrm{HA}] \gg\left[\mathrm{A}^{-}\right]$and $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from } \mathrm{HA}} \gg\left[\mathrm{OH}^{-}\right]_{\text {from } \mathrm{H}_{2} \mathrm{O}}$, so the solution is acidic.
- In an $\mathrm{A}^{-}$solution, $\left[\mathrm{A}^{-}\right] \gg[\mathrm{HA}]$ and $\left.\left[\mathrm{OH}^{-}\right]_{\text {from } \mathrm{A}^{-}} \gg \mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {from } \mathrm{H}_{2} \mathrm{O}}$, so the solution is basic.

## The Relation Between $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ of a Conjugate Acid-Base Pair

An important relationship exists between the $K_{\mathrm{a}}$ of HA and the $K_{\mathrm{b}}$ of A ${ }^{-}$, which we can see by treating the two dissociation reactions as a reaction sequence and adding them together:

$$
\begin{aligned}
& \mathrm{HA}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{A}^{-} \\
& \mathrm{A}^{-}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{HA}^{-}+\mathrm{OH}^{-} \\
& \hline 2 \mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{OH}^{-}
\end{aligned}
$$

[^27]The sum of the two dissociation reactions is the autoionization of water. Recall from Chapter 17 that, for a reaction that is the sum of two or more reactions, the overall equilibrium constant is the product of the individual equilibrium constants. Therefore, writing the expressions for each reaction gives
or

$$
\begin{align*}
\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]} \times \frac{[\mathrm{HA}]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{A}^{-}\right]} & =\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right] \\
K_{\mathrm{a}} & \times \quad K_{\mathrm{b}}=K_{\mathrm{w}} \tag{18.7}
\end{align*}
$$

This relationship allows us to find $K_{\mathrm{a}}$ of the acid in a conjugate pair given $K_{\mathrm{b}}$ of the base, and vice versa. Reference tables typically have $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ values for molecular species only. The $K_{\mathrm{b}}$ for $\mathrm{F}^{-}$or the $K_{\mathrm{a}}$ for $\mathrm{CH}_{3} \mathrm{NH}_{3}{ }^{+}$, for example, does not appear in standard tables, but you can calculate either value simply by looking up the value for the molecular conjugate species and relating it to $K_{\mathrm{w}}$. To find the $K_{\mathrm{b}}$ value for $\mathrm{F}^{-}$, for instance, we look up the $K_{\mathrm{a}}$ value for HF and apply Equation 18.7:

$$
K_{\mathrm{a}} \text { of } \mathrm{HF}=6.8 \times 10^{-4}(\text { from Appendix } \mathrm{C})
$$

So, we have

$$
K_{\mathrm{a}} \text { of } \mathrm{HF} \times K_{\mathrm{b}} \text { of } \mathrm{F}^{-}=K_{\mathrm{w}}
$$

or

$$
K_{\mathrm{b}} \text { of } \mathrm{F}^{-}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}} \text { of } \mathrm{HF}}=\frac{1.0 \times 10^{-14}}{6.8 \times 10^{-4}}=1.5 \times 10^{-11}
$$

We can use this calculated $K_{\mathrm{b}}$ value to finish solving the problem.

## SAMPLE PROBLEM 18.12 Determining the pH of a Solution of $\mathrm{A}^{-}$

PROBLEM Sodium acetate $\left(\mathrm{CH}_{3} \mathrm{COONa}\right.$, or NaAc for this problem) is used in photographic development and textile dyeing. What is the pH of 0.25 M NaAc ? $K_{\mathrm{a}}$ of acetic acid (HAc) is $1.8 \times 10^{-5}$.
PLAN From the formula ( NaAc ) and the fact that all sodium salts are water soluble, we know that the initial concentration of acetate ion, $\mathrm{Ac}^{-}$, is 0.25 M . We also know the $K_{\mathrm{a}}$ of the parent acid, $\mathrm{HAc}\left(1.8 \times 10^{-5}\right)$. We have to find the pH of the solution of $\mathrm{Ac}^{-}$, which acts as a base in water:

$$
\mathrm{Ac}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HAc}(a q)+\mathrm{OH}^{-}(a q) \quad K_{\mathrm{b}}=\frac{[\mathrm{HAc}]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{Ac}^{-}\right]}
$$

If we calculate $\left[\mathrm{OH}^{-}\right]$, we can find $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and convert it to pH . To solve for $\left[\mathrm{OH}^{-}\right]$, we need the $K_{\mathrm{b}}$ of $\mathrm{Ac}^{-}$, which we obtain from the $K_{\mathrm{a}}$ of HAc and $K_{\mathrm{w}}$. All sodium salts are soluble, so we know that $\left[\mathrm{Ac}^{-}\right]=0.25 \mathrm{M}$. Our usual assumption is that $\left[\mathrm{Ac}^{-}\right]_{\text {init }} \approx\left[\mathrm{Ac}^{-}\right]$. SOLUTION Setting up the reaction table, with $x=\left[\mathrm{Ac}^{-}\right]_{\text {reacting }}=[\mathrm{HAc}]=\left[\mathrm{OH}^{-}\right]$:

| Concentration $(\mathbf{M})$ | $\mathbf{A c}^{-}(\mathbf{a q})$ | $\mathbf{+}$ | $\mathbf{H}_{\mathbf{2}} \mathbf{O}(\mathbf{l})$ | $\rightleftharpoons$ | $\mathbf{H A c}(a \mathbf{q})$ | + |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{O H}^{-}(\mathbf{a q})$ |  |  |  |  |  |  |
| Initial | 0.25 | - |  | 0 | 0 |  |
| Change | $-x$ | - |  | $+x$ | $+x$ |  |
| Equilibrium | $0.25-x$ | - |  | $x$ | $x$ |  |

Solving for $K_{\mathrm{b}}$ :

$$
K_{\mathrm{b}}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}}}=\frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}}=5.6 \times 10^{-10}
$$

Making the assumption: Because $K_{\mathrm{b}}$ is small, $0.25 M-x \approx 0.25 M$.
Substituting into the expression for $K_{\mathrm{b}}$ and solving for $x$ :

$$
K_{\mathrm{b}}=\frac{[\mathrm{HAc}]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{Ac}^{-}\right]}=5.6 \times 10^{-10} \approx \frac{x^{2}}{0.25} \quad x=\left[\mathrm{OH}^{-}\right] \approx 1.2 \times 10^{-5} M
$$

Checking the assumption:

$$
\frac{1.2 \times 10^{-5} M}{0.25 M} \times 100=4.8 \times 10^{-3} \%(<5 \% ; \text { assumption is justified })
$$

Note that

$$
\frac{0.25}{5.6 \times 10^{-10}}=4.5 \times 10^{8}>400
$$

Solving for pH :

$$
\begin{aligned}
{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] } & =\frac{K_{\mathrm{w}}}{\left[\mathrm{OH}^{-}\right]}=\frac{1.0 \times 10^{-14}}{1.2 \times 10^{-5}}=8.3 \times 10^{-10} \mathrm{M} \\
\mathrm{pH} & =-\log \left(8.3 \times 10^{-10}\right)=9.08
\end{aligned}
$$

CHECK The $K_{\mathrm{b}}$ calculation seems reasonable: $\sim 10 \times 10^{-15} / 2 \times 10^{-5}=5 \times 10^{-10}$. Because $\mathrm{Ac}^{-}$is a weak base, $\left[\mathrm{OH}^{-}\right]>\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$; thus, $\mathrm{pH}>7$, which makes sense.
FOLLOW-UP PROBLEM 18.12 Sodium hypochlorite $(\mathrm{NaClO})$ is the active ingredient in household laundry bleach. What is the pH of 0.20 M NaClO ?

## Section Summary

The extent to which a weak base accepts a proton from water to form $\mathrm{OH}^{-}$is expressed by a base-dissociation constant, $K_{\mathrm{b}}$. - Brønsted-Lowry bases include $\mathrm{NH}_{3}$ and amines and the anions of weak acids. All produce basic solutions by accepting $\mathrm{H}^{+}$from water, which yields $\mathrm{OH}^{-}$and thus makes $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]<\left[\mathrm{OH}^{-}\right]$. • A solution of HA is acidic because $[\mathrm{HA}] \gg\left[\mathrm{A}^{-}\right]$, so $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]>\left[\mathrm{OH}^{-}\right]$. A solution of $\mathrm{A}^{-}$is basic because $\left[\mathrm{A}^{-}\right] \gg[\mathrm{HA}]$, so $\left[\mathrm{OH}^{-}\right]>\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$. By multiplying the expressions for $K_{\mathrm{a}}$ of HA and $K_{\mathrm{b}}$ of $\mathrm{A}^{-}$, we obtain $K_{\mathrm{w}}$. This relationship allows us to calculate either $K_{\mathrm{a}}$ of $\mathrm{BH}^{+}$, the cationic conjugate acid of a molecular weak base B , or $K_{\mathrm{b}}$ of $\mathrm{A}^{-}$, the anionic conjugate base of a molecular weak acid HA.

### 18.6 MOLECULAR PROPERTIES AND ACID STRENGTH

The strength of an acid depends on its ability to donate a proton, which depends in turn on the strength of the bond to the acidic proton. In this section, we apply trends inatemic and pondpropertiestedetermine the trends in acid strength of nonmetal hydrides and oxoacids and discuss the acidity of hydrated metal ions.

## Trends in Acid Strength of Nonmetal Hydrides

Two factors determine how easily a proton is released from a nonmetal hydride: the electronegativity of the central nonmetal (E) and the strength of the E-H bond. Figure 18.11 displays two periodic trends:

1. Across a period, nonmetal hydride acid strength increases. Across a period, the electronegativity of the nonmetal E determines the trend. As E becomes more electronegative, electron density around H is withdrawn, and the $\mathrm{E}-\mathrm{H}$ bond becomes more polar. As a result, $\mathrm{H}^{+}$is released more easily to an O atom of a surrounding water molecule. In aqueous solution, the hydrides of Groups $3 \mathrm{~A}(13)$ to $5 \mathrm{~A}(15)$ do not behave as acids, but an increase in acid strength is seen in Groups $6 \mathrm{~A}(16)$ and $7 \mathrm{~A}(17)$. Thus, HCl is a stronger acid than $\mathrm{H}_{2} \mathrm{~S}$ because Cl is more electronegative $(\mathrm{EN}=3.0)$ than $\mathrm{S}(\mathrm{EN}=2.5)$. The same relationship holds across each period.
2. Down a group, nonmetal hydride acid strength increases. Down a group, $\mathrm{E}-\mathrm{H}$ bond strength determines the trend. As E becomes larger, the E-H bond becomes longer and weaker, so $\mathrm{H}^{+}$comes off more easily.* Thus, the hydrohalic acids increase in strength down the group:

$$
\mathrm{HF} \ll \mathrm{HCl}<\mathrm{HBr}<\mathrm{HI}
$$

A similar trend in increasing acid strength is seen down Group 6A(16). (The trend in hydrohalic acid strength is not seen in aqueous solution, where $\mathrm{HCl}, \mathrm{HBr}$, and HI are all equally strong; we discuss how this trend is observed in Section 18.8.)

[^28]
## Trends in Acid Strength of Oxoacids

All oxoacids have the acidic $H$ atom bonded to an $O$ atom, so bond strength (length) is not a factor in their acidity, though it is with the nonmetal hydrides. Rather, as you saw in Section 14.8, two factors determine the acid strength of oxoacids: the electronegativity of the central nonmetal (E) and the number of O atoms.

1. For oxoacids with the same number of oxygens around $E$, acid strength increases with the electronegativity of $E$. Consider the hypohalous acids (written here as HOE, where E is a halogen atom). The more electronegative E is, the more electron density it pulls from the $\mathrm{O}-\mathrm{H}$ bond; the more polar the $\mathrm{O}-\mathrm{H}$ bond becomes, the more easily $\mathrm{H}^{+}$is lost (Figure 18.12A). Since electronegativity decreases down the group, we predict that acid strength decreases: $\mathrm{HOCl}>\mathrm{HOBr}>\mathrm{HOI}$. Our prediction is confirmed by the $K_{\mathrm{a}}$ values:

$$
K_{\mathrm{a}} \text { of } \mathrm{HOCl}=2.9 \times 10^{-8} \quad K_{\mathrm{a}} \text { of } \mathrm{HOBr}=2.3 \times 10^{-9} \quad K_{\mathrm{a}} \text { of } \mathrm{HOI}=2.3 \times 10^{-11}
$$

We also predict (correctly) that in Group $6 \mathrm{~A}(16), \mathrm{H}_{2} \mathrm{SO}_{4}$ is stronger than $\mathrm{H}_{2} \mathrm{SeO}_{4}$; in Group $5 \mathrm{~A}(15), \mathrm{H}_{3} \mathrm{PO}_{4}$ is stronger than $\mathrm{H}_{3} \mathrm{AsO}_{4}$, and so forth.
2. For oxoacids with different numbers of oxygens around a given E, acid strength increases with number of $O$ atoms. The electronegative O atoms pull electron density away from E, which makes the O-H bond more polar. The more O atoms present, the greater the shift in electron density, and the more easily the $\mathrm{H}^{+}$ion comes off (Figure 18.12B). Therefore, we predict, for instance, that chlorine oxoacids (written here as $\mathrm{HOClO}_{n}$, with $n$ from 0 to 3 ) increase in strength in the order $\mathrm{HOCl}<\mathrm{HOClO}<\mathrm{HOClO}_{2}<\mathrm{HOClO}_{3}$. Once again, the $K_{\mathrm{a}}$ values support the prediction:

$$
\begin{aligned}
& K_{\mathrm{a}} \text { of } \mathrm{HOCl} \text { (hypochlorous acid) }=2.9 \times 10^{-8} \\
& K_{\mathrm{a}} \text { of } \mathrm{HOClO} \text { (chloreracig) } \approx \mathrm{PDP} \mathrm{P}^{2} 10 \text { nhancer } \\
& K_{\mathrm{a}} \text { of } \mathrm{HOClO}_{2} \text { (chloric acid) } \approx 1 \\
& K_{\mathrm{a}} \text { of } \mathrm{HOClO}_{3} \text { (perchloric acid) }=>10^{7}
\end{aligned}
$$

It follows from this that $\mathrm{HNO}_{3}$ is stronger than $\mathrm{HNO}_{2}$, that $\mathrm{H}_{2} \mathrm{SO}_{4}$ is stronger than $\mathrm{H}_{2} \mathrm{SO}_{3}$, and so forth.

## Acidity of Hydrated Metal Ions

The aqueous solutions of certain metal ions are acidic because the hydrated metal ion transfers an $\mathrm{H}^{+}$ion to water. Consider a general metal nitrate, $\mathrm{M}\left(\mathrm{NO}_{3}\right)_{n}$, as it dissolves in water. The ions separate and become bonded to a specific number of surrounding $\mathrm{H}_{2} \mathrm{O}$ molecules. This equation shows the hydration of the cation $\left(\mathrm{M}^{n+}\right)$ with $\mathrm{H}_{2} \mathrm{O}$ molecules; hydration of the anion $\left(\mathrm{NO}_{3}{ }^{-}\right)$is indicated by (aq):

$$
\mathrm{M}\left(\mathrm{NO}_{3}\right)_{n}(s)+x \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{x}{ }^{n+}(a q)+n \mathrm{NO}_{3}{ }^{-}(a q)
$$

Figure 18.12 The relative strengths
of oxoacids. A, Among these hypohalous acids, HOCl is the strongest and HO the weakest. Because Cl is the most electronegative of the halogens shown here, it withdraws electron density (indicated by thickness of green arrow) from the O-H bond most effectively, making that bond most polar in HOCl (indicated by the relative sizes of the $\delta$ symbols). B, Among the chlorine oxoacids, the additional O atoms in $\mathrm{HOClO}_{3}$ pull electron density from the $\mathrm{O}-\mathrm{H}$ bond, making the bond much more polar than that in HOCl .

## Table $18.7 K_{\mathrm{a}}$ Values of Some

Hydrated Metal lons at $25^{\circ} \mathrm{C}$

| Free Ion | Hydrated Ion | $K_{\mathrm{a}}$ |
| :---: | :---: | :---: |
| $\mathrm{Fe}^{3+}$ | $\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q)$ | $6 \times 10^{-3}$ |
| $\mathrm{Sn}^{2+}$ | $\mathrm{Sn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}(a q)$ | $4 \times 10^{-4}$ |
| $\mathrm{Cr}^{3+}$ | $\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q)$ | $1 \times 10^{-4}$ |
| $\mathrm{Al}^{3+}$ | $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q)$ | $1 \times 10^{-5}$ |
| $\mathrm{Cu}^{2+}$ | $\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}(a q)$ | $3 \times 10^{-8}$ |
| $\mathrm{Pb}^{2+}$ | $\mathrm{Pb}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}(a q)$ | $3 \times 10^{-8}$ |
| $\mathrm{Zn}^{2+}$ | $\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}(\mathrm{aq})$ | $1 \times 10^{-9}$ |
| $\mathrm{Co}^{2+}$ | $\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}(\mathrm{aq})$ | $2 \times 10^{-10}$ |
| $\mathrm{Ni}^{2+}$ | $\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}(a q)$ | $1 \times 10^{-10}$ |

Figure 18.13 The acidic behavior of the hydrated $\mathrm{Al}^{3+}$ ion. When a metal ion enters water, it is hydrated as water molecules bond to it. If the ion is small and multiply charged, as is the $\mathrm{Al}^{3+}$ ion, it pulls sufficient electron density from the $\mathrm{O}-\mathrm{H}$ bonds of the attached water molecules to make the bonds more polar, and an $\mathrm{H}^{+}$ion is transferred to a nearby water molecule.

If the metal ion, $\mathrm{M}^{n+}$, is small and highly charged, it has a high charge density and withdraws sufficient electron density from the $\mathrm{O}-\mathrm{H}$ bonds of these bonded water molecules for a proton to be released. That is, the hydrated cation, $\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{x}{ }^{n+}$, acts as a typical Brønsted-Lowry acid. In the process, the bound $\mathrm{H}_{2} \mathrm{O}$ molecule that releases the proton becomes a bound $\mathrm{OH}^{-}$ion:

$$
\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{x}{ }^{n+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{x-1} \mathrm{OH}^{(n-1)+}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)
$$

Each type of hydrated metal ion that releases a proton has a characteristic $K_{\mathrm{a}}$ value. Table 18.7 shows some common examples (also see Appendix C).

Aluminum ion, for example, has the small size and high positive charge needed to produce an acidic solution. When an aluminum salt, such as $\mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}$, dissolves in water, the following steps occur:

$$
\mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q)+\underset{\text { [dissolution and hydration] }}{3 \mathrm{NO}_{3}^{-}(a q)}
$$

$$
\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{OH}^{2+}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)
$$

[dissociation of weak acid]
Note the formulas of the hydrated metal ions in the last step. When $\mathrm{H}^{+}$is released, the number of bound $\mathrm{H}_{2} \mathrm{O}$ molecules decreases by 1 (from 6 to 5) and the number of bound $\mathrm{OH}^{-}$ions increases by 1 (from 0 to 1 ), which reduces the ion's positive charge by 1 (from 3 to 2) (Figure 18.13).

Through its ability to withdraw electron density from the $\mathrm{O}-\mathrm{H}$ bonds of the bonded water molecules, a small, highly charged central metal ion behaves like a central electronegative atom in an oxoacid. Salts of most $\mathrm{M}^{2+}$ and $\mathrm{M}^{3+}$ ions yield acidic aqueous solutions.

## Section Summary

The strength of an acid depends on the ease with which the ionizable proton is released. - For nonmetal hydrides, acid strength increases across a period, with the electronegativity of the nonmetal ( E ), and down a group, with the length of the E-H bond. - For oxoacids with the same number of $O$ atoms, acid strength increases with electronegativity of E ; for oxoacids with the same E , acid strength increases with number of O atoms. - Small, highly charged metal ions are acidic in water because they withdraw electron density from the $\mathrm{O}-\mathrm{H}$ bonds of bound $\mathrm{H}_{2} \mathrm{O}$ molecules, releasing an $\mathrm{H}^{+}$ion to the solution.

### 18.7 ACID-BASE PROPERTIES OF SALT SOLUTIONS

When a salt dissolves, one or both of its ions may react with the water and affect the pH of the solution. Up to now you've seen that cations of weak bases (such as $\mathrm{NH}_{4}^{+}$) are acidic, anions of weak acids (such as $\mathrm{CN}^{-}$) are basic, and small, highly charged metal cations (such as $\mathrm{Al}^{3+}$ ) are acidic. In addition, certain ions
(such as $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}$and $\mathrm{HCO}_{3}{ }^{-}$) can act as an acid or a base, and we must calculate whether their solutions are acidic or basic. In this section, we'll classify the acidbase behavior of the various types of salt solutions.

## Salts That Yield Neutral Solutions

A salt consisting of the anion of a strong acid and the cation of a strong base yields a neutral solution because the ions do not react with water. To see why the ions don't react, let's consider the dissociation of the parent acid and base. When a strong acid such as $\mathrm{HNO}_{3}$ dissolves, complete dissociation takes place:

$$
\mathrm{HNO}_{3}(l)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{NO}_{3}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)
$$

$\mathrm{H}_{2} \mathrm{O}$ is a much stronger base than $\mathrm{NO}_{3}{ }^{-}$, so the reaction proceeds essentially to completion. The same argument can be made for any strong acid: the anion of a strong acid is a much weaker base than water. Therefore, a strong acid anion is hydrated, but nothing further happens.

Now consider the dissociation of a strong base, such as NaOH :

$$
\mathrm{NaOH}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{Na}^{+}(a q)+\mathrm{OH}^{-}(a q)
$$

When $\mathrm{Na}^{+}$enters water, it becomes hydrated but nothing further happens. The cations of all strong bases behave this way.

The anions of strong acids are the halide ions, except $\mathrm{F}^{-}$, and those of strong oxoacids, such as $\mathrm{NO}_{3}{ }^{-}$and $\mathrm{ClO}_{4}{ }^{-}$. The cations of strong bases are those from Group $1 \mathrm{~A}(1)$ and $\mathrm{Ca}^{2+}, \mathrm{Sr}^{2+}$, and $\mathrm{Ba}^{2+}$ from Group $2 \mathrm{~A}(2)$. Salts containing only these ions, such as NaCl and $\mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}$, yield neutral solutions because no reaction takes place between the ions and water.

## Salts That Yield Acidic Solutions

A salt consisting of the anion of a strongacid and the cation of a weak base yields an acidic solution because the cation acts as a weak acid, and the anion does not react. For example, $\mathrm{NH}_{4} \mathrm{Cl}$ produces an acidic solution because the $\mathrm{NH}_{4}{ }^{+}$ ion, the cation that forms from the weak base $\mathrm{NH}_{3}$, is a weak acid, and the $\mathrm{Cl}^{-}$ ion, the anion of a strong acid, does not react:

$$
\begin{aligned}
\mathrm{NH}_{4} \mathrm{Cl}(s) & \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{NH}_{4}^{+}(a q)+\mathrm{Cl}^{-}(a q) \\
\mathrm{NH}_{4}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) & \text { [dissolution and hydration] } \\
\mathrm{NH}_{3}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) & \text { [dissociation of weak acid] }
\end{aligned}
$$

As you saw earlier, small, highly charged metal ions make up another group of cations that yield $\mathrm{H}_{3} \mathrm{O}^{+}$in solution. For example, $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}$ produces an acidic solution because the hydrated $\mathrm{Fe}^{3+}$ ion acts as a weak acid, whereas the $\mathrm{NO}_{3}{ }^{-}$ ion, the anion of a strong acid, does not react:

$$
\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{3+}(a q)+3 \mathrm{NO}_{3}{ }^{-}(a q)
$$

[dissolution and hydration]
$\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{OH}^{2+}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)$
[dissociation of weak acid]

## Salts That Yield Basic Solutions

A salt consisting of the anion of a weak acid and the cation of a strong base yields a basic solution in water because the anion acts as a weak base, and the cation does not react. The anion of a weak acid accepts a proton from water to yield $\mathrm{OH}^{-}$ion. Sodium acetate, for example, yields a basic solution because the $\mathrm{Na}^{+}$ion, the cation of a strong base, does not react with water, and the $\mathrm{CH}_{3} \mathrm{COO}^{-}$ ion, the anion of the weak acid $\mathrm{CH}_{3} \mathrm{COOH}$, acts as a weak base:

$$
\begin{array}{rr}
\mathrm{CH}_{3} \mathrm{COONa}(s) & \stackrel{\mathrm{H}_{2} \mathrm{O}}{\longrightarrow} \mathrm{Na}^{+}(a q)+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q) \\
\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) & \text { [dissolution and hydration] } \\
\mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{OH}^{-}(a q) & \text { [reaction of weak base] }
\end{array}
$$

## SAMPLE PROBLEM 18.13 Predicting Relative Acidity of Salt Solutions

PROBLEM Predict whether aqueous solutions of the following are acidic, basic, or neutral, and write an equation for the reaction of any ion with water:
(a) Potassium perchlorate, $\mathrm{KClO}_{4}$
(b) Sodium benzoate, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COONa}$
(c) Chromium(III) nitrate, $\mathrm{Cr}\left(\mathrm{NO}_{3}\right)_{3}$

PLAN We examine the formulas to determine the cations and anions. Depending on the nature of these ions, the solution will be neutral (strong-acid anion and strong-base cation), acidic (weak-base cation and strong-acid anion or highly charged metal cation), or basic (weak-acid anion and strong-base cation).
SOLUTION (a) Neutral. The ions are $\mathrm{K}^{+}$and $\mathrm{ClO}_{4}^{-}$. The $\mathrm{K}^{+}$ion is from the strong base KOH , and the $\mathrm{ClO}_{4}{ }^{-}$anion is from the strong acid $\mathrm{HClO}_{4}$. Neither ion reacts with water. (b) Basic. The ions are $\mathrm{Na}^{+}$and $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-} . \mathrm{Na}^{+}$is the cation of the strong base NaOH and does not react with water. The benzoate ion, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}$, is from the weak acid benzoic acid, so it reacts with water to produce $\mathrm{OH}^{-}$ion:

$$
\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}(a q)+\mathrm{OH}^{-}(a q)
$$

(c) Acidic. The ions are $\mathrm{Cr}^{3+}$ and $\mathrm{NO}_{3}{ }^{-}$. The $\mathrm{NO}_{3}{ }^{-}$ion is the anion of the strong acid $\mathrm{HNO}_{3}$, so it does not react with water. $\mathrm{Cr}^{3+}$ is a small metal ion with a high positive charge, so the hydrated ion, $\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$, reacts with water to produce $\mathrm{H}_{3} \mathrm{O}^{+}$:

$$
\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{OH}^{2+}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)
$$

FOLLOW-UP PROBLEM 18.13 Write equations to predict whether solutions of the following salts are acidic, basic, or neutral: (a) $\mathrm{KClO}_{2}$; (b) $\mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{NO}_{3}$; (c) CsI.

## Salts of Weakly Acidic Cations and Weakly Basic Anions

If a saltensists of cationthatfan actasaweak acid and an anion that can act as a weak base, both ions react with water. In these cases, the overall acidity of the solution depends on the relative acid strength $\left(K_{\mathrm{a}}\right)$ or base strength $\left(K_{\mathrm{b}}\right)$ of the separated ions. For example, will an aqueous solution of ammonium cyanide, $\mathrm{NH}_{4} \mathrm{CN}$, be acidic or basic? First, we write equations for any reactions that occur between the separated ions and water. Ammonium ion is the conjugate acid of a weak base, so it acts as a weak acid:

$$
\mathrm{NH}_{4}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{3}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)
$$

Cyanide ion is the anion of the weak acid HCN and it acts as a weak base:

$$
\mathrm{CN}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HCN}(a q)+\mathrm{OH}^{-}(a q)
$$

The reaction that goes farther to the right will have the greater influence on the pH of the solution, so we must compare the $K_{\mathrm{a}}$ of $\mathrm{NH}_{4}^{+}$with the $K_{\mathrm{b}}$ of $\mathrm{CN}^{-}$. Recall that only molecular compounds are listed in $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ tables, so we first have to calculate these values for the ions:

$$
\begin{aligned}
K_{\mathrm{a}} \text { of } \mathrm{NH}_{4}^{+} & =\frac{K_{\mathrm{w}}}{K_{\mathrm{b}} \text { of } \mathrm{NH}_{3}}=\frac{1.0 \times 10^{-14}}{1.76 \times 10^{-5}}=5.7 \times 10^{-10} \\
K_{\mathrm{b}} \text { of } \mathrm{CN}^{-} & =\frac{K_{\mathrm{w}}}{K_{\mathrm{a}} \text { of } \mathrm{HCN}}=\frac{1.0 \times 10^{-14}}{6.2 \times 10^{-10}}=1.6 \times 10^{-5}
\end{aligned}
$$

The difference in magnitude of the equilibrium constants ( $K_{\mathrm{b}} \approx 3 \times 10^{4} K_{\mathrm{a}}$ ) indicates that the acceptance of a proton from $\mathrm{H}_{2} \mathrm{O}$ by $\mathrm{CN}^{-}$proceeds much further than the donation of a proton to $\mathrm{H}_{2} \mathrm{O}$ by $\mathrm{NH}_{4}{ }^{+}$. Thus, because $K_{\mathrm{b}}$ of $\mathrm{CN}^{-}>K_{\mathrm{a}}$ of $\mathrm{NH}_{4}^{+}$, the $\mathrm{NH}_{4} \mathrm{CN}$ solution is basic.

## Salts of Amphiprotic Anions

The only salts left to consider are those in which the cation comes from a strong base and the anion comes from a polyprotic acid and still has one or more ionizable protons attached. These anions are amphiprotic-they can release a proton
to water, thereby acting as an acid, or they can abstract a proton from water, thereby acting as a base. As with the previous type of salt, we have to compare the magnitudes of $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$, but here, we compare $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ of the anion.

For example, $\mathrm{Na}_{2} \mathrm{HPO}_{4}$ consists of $\mathrm{Na}^{+}$, the cation of a strong base, which does not react with water, and $\mathrm{HPO}_{4}{ }^{2-}$, the second anion of the weak polyprotic acid $\mathrm{H}_{3} \mathrm{PO}_{4}$. Dissolved in water, the salt can undergo these three reactions. Does reaction 2 or 3 go farther to the right?

1. $\quad \mathrm{Na}_{2} \mathrm{HPO}_{4}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} 2 \mathrm{Na}^{+}(a q)+\mathrm{HPO}_{4}{ }^{2-}(a q) \quad$ [dissolution and hydration]
2. $\mathrm{HPO}_{4}{ }^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{PO}_{4}{ }^{3-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \quad$ [acting as a weak acid]

From Appendix C, we find that the $K_{\mathrm{a}}$ of $\mathrm{HPO}_{4}{ }^{2-}$ is $4.2 \times 10^{-13}$
3. $\mathrm{HPO}_{4}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q)+\mathrm{OH}^{-}(a q) \quad$ [acting as a weak base]

$$
K_{\mathrm{b}} \text { of } \mathrm{HPO}_{4}{ }^{2-}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}} \text { of } \mathrm{H}_{2} \mathrm{PO}_{4}^{-}} \quad \text { or } \quad \frac{1.0 \times 10^{-14}}{6.3 \times 10^{-8}}=1.6 \times 10^{-7}
$$

Because $K_{\mathrm{b}}>K_{\mathrm{a}}, \mathrm{HPO}_{4}{ }^{2-}$ acts as a base, and a solution of $\mathrm{Na}_{2} \mathrm{HPO}_{4}$ is basic.
Table 18.8 displays the acid-base behavior of the various types of salts in water.

Table 18.8 The Behavior of Salts in Water

| Salt Solution: Examples | pH | Nature of Ions | Ion That Reacts with Water: Example |
| :---: | :---: | :---: | :---: |
| Neutral: $\mathrm{NaCl}, \mathrm{KBr}, \mathrm{Ba}\left(\mathrm{NO}_{3}\right)_{2}$ | 7.0 | Cation of strong base Anion of strong acid | None |

## SAMPLE PROBLEM 18.14 Predicting the Relative Acidity of a Salt Solution from $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ of the Ions

PROBLEM Determine whether an aqueous solution of zinc formate, $\mathrm{Zn}(\mathrm{HCOO})_{2}$, is acidic, basic, or neutral.
PLAN The formula consists of the small, highly charged, and therefore weakly acidic, $\mathrm{Zn}^{2+}$ cation and the weakly basic $\mathrm{HCOO}^{-}$anion of the weak acid HCOOH . To determine the relative acidity of the solution, we write equations that show the reactions of the ions with water, and then find $K_{\mathrm{a}}$ of $\mathrm{Zn}^{2+}$ (from Appendix C) and calculate $K_{\mathrm{b}}$ of $\mathrm{HCOO}^{-}$(from $K_{\mathrm{a}}$ of HCOOH in Appendix C) to see which ion reacts to a greater extent.

SOLUTION Writing the reactions with water:

$$
\begin{gathered}
\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}^{2+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{OH}^{+}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \\
\mathrm{HCOO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HCOOH}(a q)+\mathrm{OH}^{-}(a q)
\end{gathered}
$$

Obtaining $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ of the ions: The $K_{\mathrm{a}}$ of $\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}(\mathrm{aq})$ is $1 \times 10^{-9}$. We obtain $K_{\mathrm{a}}$ of HCOOH and solve for $K_{\mathrm{b}}$ of $\mathrm{HCOO}^{-}$:

$$
K_{\mathrm{b}} \text { of } \mathrm{HCOO}^{-}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}} \text { of } \mathrm{HCOOH}}=\frac{1.0 \times 10^{-14}}{1.8 \times 10^{-4}}=5.6 \times 10^{-11}
$$

$K_{\mathrm{a}}$ of $\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}>K_{\mathrm{b}}$ of $\mathrm{HCOO}^{-}$, so the solution is acidic.
FOLLOW-UP PROBLEM 18.14 Determine whether solutions of the following salts are acidic, basic, or neutral: (a) $\mathrm{Cu}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2}$; (b) $\mathrm{NH}_{4} \mathrm{~F}$; (c) $\mathrm{KHSO}_{3}$.

## Section Summary

Salts that always yield a neutral solution consist of ions that do not react with water.

- Salts that always yield an acidic solution contain an unreactive anion and a cation that releases a proton to water. - Salts that always yield a basic solution contain an unreactive cation and an anion that accepts a proton from water. - If both cation and anion react with water, the ion that reacts to the greater extent (higher $K$ ) determines the acidity or basicity of the salt solution. - If the anion is amphiprotic (first anion of a polyprotic acid), the strength of the anion as an acid $\left(K_{\mathrm{a}}\right)$ or as a base $\left(K_{\mathrm{b}}\right)$ determines the acidity of the salt.

### 18.8 GENERALIZING THE BRØNSTED-LOWRY CONCEPT: THE LEVELING EFFECT <br> Apago PDF Enhancer

We conclude our focus on the Brønsted-Lowry concept with an important principle that holds for acid-base behavior in any solvent. Notice that, in $\mathrm{H}_{2} \mathrm{O}$, all Brønsted-Lowry acids yield $\mathrm{H}_{3} \mathrm{O}^{+}$and all Brønsted-Lowry bases yield $\mathrm{OH}^{-}$ -the ions that form when the solvent autoionizes. In general, an acid yields the cation and a base yields the anion of solvent autoionization.

This idea lets us examine a question you may have been wondering about: why are all strong acids and strong bases equally strong in water? The answer is that in water, the strongest acid possible is $\mathrm{H}_{3} \mathrm{O}^{+}$and the strongest base possible is $\mathrm{OH}^{-}$. The moment we put some gaseous HCl in water, it reacts with the base $\mathrm{H}_{2} \mathrm{O}$ and forms $\mathrm{H}_{3} \mathrm{O}^{+}$. The same holds for $\mathrm{HNO}_{3}, \mathrm{H}_{2} \mathrm{SO}_{4}$, and any strong acid. All strong acids are equally strong in water because they dissociate completely to form $\mathrm{H}_{3} \mathrm{O}^{+}$. Given that the strong acid is no longer present, we are actually observing the acid strength of $\mathrm{H}_{3} \mathrm{O}^{+}$.

Similarly, strong bases, such as $\mathrm{Ba}(\mathrm{OH})_{2}$, dissociate completely in water to yield $\mathrm{OH}^{-}$. Even those that do not contain hydroxide ions in the solid, such as $\mathrm{K}_{2} \mathrm{O}$, do so. The oxide ion, which is a stronger base than $\mathrm{OH}^{-}$, immediately takes a proton from water to form $\mathrm{OH}^{-}$:

$$
2 \mathrm{~K}^{+}(a q)+\mathrm{O}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{~K}^{+}(a q)+2 \mathrm{OH}^{-}(a q)
$$

No matter what species we try, any acid stronger than $\mathrm{H}_{3} \mathrm{O}^{+}$simply donates its proton to $\mathrm{H}_{2} \mathrm{O}$, and any base stronger than $\mathrm{OH}^{-}$accepts a proton from $\mathrm{H}_{2} \mathrm{O}$. Thus, water exerts a leveling effect on any strong acid or base by reacting with it to form the products of water's autoionization. Acting as a base, water levels the strength of all strong acids by making them appear equally strong, and acting as an acid, it levels the strength of all strong bases as well.

To rank strong acids in terms of relative strength, we must dissolve them in a solvent that is a weaker base than water, one that accepts their protons less readily. For example, you saw in Figure 18.11 that the hydrohalic acids increase in
strength as the halogen becomes larger, as a result of the longer, weaker $\mathrm{H}-\mathrm{X}$ bond. In water, HF is weaker than the other hydrogen halides, but $\mathrm{HCl}, \mathrm{HBr}$, and HI appear equally strong because water causes them to dissociate completely. When we dissolve them in pure acetic acid, however, the acetic acid acts as the base and accepts a proton from the acids:
$\begin{array}{c}\text { acid } \\ \text { base } \\ \mathrm{HCl}(g)\end{array}+\mathrm{CH}_{3} \mathrm{COOH}(l) \rightleftharpoons \mathrm{Cl}^{-}($acet $)+\mathrm{CH}_{3} \mathrm{COOH}_{2}{ }^{+}$(acet) $)$
[The use of (acet) instead of (aq) indicates solvation by $\mathrm{CH}_{3} \mathrm{COOH}$.] However, because acetic acid is a weaker base than water, the three acids protonate it to different extents. Measurements show that HI protonates the solvent to a greater extent than HBr , and HBr does so more than HCl ; that is, in pure acetic acid, $K_{\mathrm{HI}}>K_{\mathrm{HBr}}>K_{\mathrm{HCl}}$. Therefore, HCl is a weaker acid than HBr , which is weaker than HI. Similarly, the relative strength of strong bases is determined in a solvent that is a weaker acid than $\mathrm{H}_{2} \mathrm{O}$, such as liquid $\mathrm{NH}_{3}$.

## Section Summary

Strong acids (or strong bases) dissociate completely to yield $\mathrm{H}_{3} \mathrm{O}^{+}$(or $\mathrm{OH}^{-}$) in water; in effect, water equalizes (levels) their strengths. Acids that are equally strong in water show differences in strength when dissolved in a solvent that is a weaker base than water, such as acetic acid.

### 18.9 ELECTRON-PAIR DONATION AND THE LEWIS ACID-BASE DEFINITION-

The final acid-base concept we consider was developed by Gilbert N. Lewis, whose contribution to understanding the importance of valence electron pairs in molecular bonding we discussed in Chapter 9. Whereas the Brønsted-Lowry concept focuses on the proton in defining a species as an acid or a base, the Lewis concept highlights the role of the electron pair. The Lewis acid-base definition holds that

- A base is any species that donates an electron pair.
- An acid is any species that accepts an electron pair.

The Lewis definition, like the Brønsted-Lowry definition, requires that a base have an electron pair to donate, so it does not expand the classes of bases. However, it greatly expands the classes of acids. Many species, such as $\mathrm{CO}_{2}$ and $\mathrm{Cu}^{2+}$, that do not contain H in their formula (and thus cannot be Brønsted-Lowry acids) function as Lewis acids by accepting an electron pair in their reactions. Lewis stated his objection to the proton as the defining feature of an acid this way: "To restrict the group of acids to those substances which contain hydrogen interferes as seriously with the systematic understanding of chemistry as would the restriction of the term oxidizing agent to those substances containing oxygen." Moreover, in the Lewis sense, the proton itself functions as an acid because it accepts the electron pair donated by a base:

$$
\mathrm{B}: \overparen{+\mathrm{H}^{+}} \rightleftharpoons \mathrm{B}-\mathrm{H}^{+}
$$

Thus, all Brønsted-Lowry acids donate $H^{+}$, a Lewis acid.
The product of any Lewis acid-base reaction is called an adduct, a single species that contains a new covalent bond:

$$
\hat{A^{\prime}+}: \mathrm{B} \rightleftharpoons \mathrm{~A}-\mathrm{B} \text { (adduct) }
$$

Thus, the Lewis concept radically broadens the idea of acid-base reactions. What to Arrhenius was the formation of $\mathrm{H}_{2} \mathrm{O}$ from $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$became, to Brønsted and Lowry, the transfer of a proton from a stronger acid to a stronger base to form a weaker base and weaker acid. To Lewis, the same process became the donation and acceptance of an electron pair to form a covalent bond in an adduct.

As we've seen, the key feature of a Lewis base is a lone pair of electrons to donate. The key feature of a Lewis acid is a vacant orbital (or the ability to rearrange its bonds to form one) to accept that lone pair and form a new bond. In the upcoming discussion, you'll encounter a variety of neutral molecules and positively charged ions that satisfy this requirement.

## Molecules as Lewis Acids

Many neutral molecules function as Lewis acids. In every case, the atom that accepts the electron pair is low in electron density because of either an electron deficiency or a polar multiple bond.
Lewis Acids with Electron-Deficient Atoms Some molecular Lewis acids contain a central atom that is electron deficient, one surrounded by fewer than eight valence electrons. The most important of these acids are covalent compounds of the Group $3 \mathrm{~A}(13)$ elements boron and aluminum. As noted in Chapters 10 and 14, these compounds react to complete their octet. For example, boron trifluoride accepts an electron pair from ammonia to form a covalent bond in a gaseous Lewis acid-base reaction:

## 

Unexpected solubility behavior is sometimes due to adduct formation. Aluminum chloride, for instance, dissolves freely in relatively nonpolar diethyl ether because of a Lewis acid-base reaction, in which the ether's O atom donates an electron pair to Al to form a covalent bond:

This acidic behavior of boron and aluminum halides is put to use in many organic syntheses. For example, toluene, an important solvent and organic reagent, can be made by the action of $\mathrm{CH}_{3} \mathrm{Cl}$ on benzene in the presence of $\mathrm{AlCl}_{3}$. The Lewis acid $\mathrm{AlCl}_{3}$ abstracts the Lewis base $\mathrm{Cl}^{-}$from $\mathrm{CH}_{3} \mathrm{Cl}$ to form an adduct that has a reactive $\mathrm{CH}_{3}{ }^{+}$group, which attacks the benzene ring:

Lewis Acids with Polar Multiple Bonds Molecules that contain a polar double bond also function as Lewis acids. As the electron pair on the Lewis base approaches the partially positive end of the double bond, one of the bonds breaks to form the new bond in the adduct. For example, consider the reaction that occurs when $\mathrm{SO}_{2}$ dissolves in water. The electronegative O atoms in $\mathrm{SO}_{2}$ withdraw electron density from the central S , so it is partially positive. The O atom of water
donates a lone pair to the S , breaking one of the $\pi$ bonds and forming an $\mathrm{S}-\mathrm{O}$ bond, and a proton is transferred from water to that O . The resulting adduct is sulfurous acid, and the overall process is

The formation of carbonates from a metal oxide and carbon dioxide is an analogous reaction that occurs in a nonaqueous heterogeneous system. The $\mathrm{O}^{2-}$ ion (shown below from CaO ) donates an electron pair to the partially positive C in $\mathrm{CO}_{2}$, a $\pi$ bond breaks, and the $\mathrm{CO}_{3}{ }^{2-}$ ion forms as the adduct:

## Metal Cations as Lewis Acids

Earlier we saw that certain hydrated metal ions act as Brønsted-Lowry acids. In the Lewis sense, the hydration process itself is an acid-base reaction. The hydrated cation is the adduct, as lone electron pairs on the O atoms of water form covalent bonds to the positively charged ion; thus, any metal ion acts as a Lewis acid when it dissolves in water:

Ammonia is a stronger Lewis base than water because it displaces $\mathrm{H}_{2} \mathrm{O}$ from a hydrated ion when aqueous $\mathrm{NH}_{3}$ is added:

We discuss the equilibrium nature of these acid-base reactions in greater detail in Chapter 19, and we investigate the structures of these ions in Chapter 23.

Many biomolecules are Lewis adducts with central metal ions. Most often, O and N atoms of organic groups, with their lone pairs, serve as the Lewis bases. Chlorophyll is a Lewis adduct of a central $\mathrm{Mg}^{2+}$ ion and the four N atoms of an organic tetrapyrrole ring system (Figure 18.14). Vitamin $\mathrm{B}_{12}$ has a similar structure with a central $\mathrm{Co}^{3+}$, and so does heme, but with a central $\mathrm{Fe}^{2+}$. Several other metal ions, such as $\mathrm{Zn}^{2+}, \mathrm{Mo}^{2+}$, and $\mathrm{Cu}^{2+}$, are bound at the active sites of enzymes and function as Lewis acids in the catalytic action.

## SAMPLE PROBLEM 18.15 Identifying Lewis Acids and Bases

PROBLEM Identify the Lewis acids and Lewis bases in the following reactions:
(a) $\mathrm{H}^{+}+\mathrm{OH}^{-} \rightleftharpoons \mathrm{H}_{2} \mathrm{O}$
(b) $\mathrm{Cl}^{-}+\mathrm{BCl}_{3} \rightleftharpoons \mathrm{BCl}_{4}^{-}$
(c) $\mathrm{K}^{+}+6 \mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{K}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{+}$

PLAN We examine the formulas to see which species accepts the electron pair (Lewis acid) and which donates it (Lewis base) in forming the adduct.

Figure $\mathbf{1 8 . 1 4}$ The $\mathrm{Mg}^{2+}$ ion as a Lewis acid in the chlorophyll molecule. Many biomolecules contain metal ions that act as Lewis acids. In chlorophyll, $\mathrm{Mg}^{2+}$ accepts electron pairs from surrounding N atoms that are part of the large organic portion of the molecule.

SOLUTION (a) The $\mathrm{H}^{+}$ion accepts an electron pair from the $\mathrm{OH}^{-}$ion in forming a bond. $\mathrm{H}^{+}$is the acid and $\mathrm{OH}^{-}$is the base.
(b) The $\mathrm{Cl}^{-}$ion has four lone pairs and uses one to form a new bond to the central B . Therefore, $\mathrm{BCl}_{3}$ is the acid and $\mathrm{Cl}^{-}$is the base.
(c) The $\mathrm{K}^{+}$ion does not have any valence electrons to provide, so the bond is formed when electron pairs from O atoms of water enter empty orbitals on $\mathrm{K}^{+}$. Thus, $\mathrm{K}^{+}$is the acid and $\mathrm{H}_{2} \mathrm{O}$ is the base.
CHECK The Lewis acids $\left(\mathrm{H}^{+}, \mathrm{BCl}_{3}\right.$, and $\left.\mathrm{K}^{+}\right)$each have an unfilled valence shell that can accept an electron pair from the Lewis bases $\left(\mathrm{OH}^{-}, \mathrm{Cl}^{-}\right.$, and $\left.\mathrm{H}_{2} \mathrm{O}\right)$.
FOLLOW-UP PROBLEM 18.15 Identify the Lewis acids and Lewis bases in each of the following reactions:
(a) $\mathrm{OH}^{-}+\mathrm{Al}(\mathrm{OH})_{3} \rightleftharpoons \mathrm{Al}(\mathrm{OH})_{4}{ }^{-}$
(b) $\mathrm{SO}_{3}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{2} \mathrm{SO}_{4}$
(c) $\mathrm{Co}^{3+}+6 \mathrm{NH}_{3} \rightleftharpoons \mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+}$

## An Overview of Acid-Base Definitions

By looking closely at the essential chemical change involved, chemists can see a common theme in reactions as diverse as a standardized base being used to analyze an unknown fatty acid, baking soda being used in breadmaking, and even oxygen binding to hemoglobin in a blood cell. From this broader chemical perspective, the diversity of acid-base reactions takes on more unity. Let's stand back and survey the scope of the three acid-base definitions and see how they fit together.

The Arrhenius definition, which was the first attempt at describing acids and bases on the molecular level, is the most limited and narrow of the three definitions. It applies only to species whose structures include an H atom or an OH group that is released as an ion when the species dissolves in water. Because relathetyafy specesthave these strecturererequisites, Arrhenius acid-base reactions are relatively few in number, and all such reactions occur in $\mathrm{H}_{2} \mathrm{O}$ and result in the formation of $\mathrm{H}_{2} \mathrm{O}$.

The Brønsted-Lowry definition is more general, seeing acid-base reactions as proton-transfer processes and eliminating the requirement that they occur in water. Whereas a Brønsted-Lowry acid, like an Arrhenius acid, still must have an H, a Brønsted-Lowry base is defined as any species with an electron pair available to accept a transferred proton. This definition includes a great many more species as bases. Furthermore, it defines the acid-base reaction in terms of conjugate acidbase pairs, with an acid and a base on both sides of the reaction. The system reaches an equilibrium state based on the relative strengths of the acid, the base, and their conjugates.

The Lewis definition has the widest scope of the three. The defining event of a Lewis acid-base reaction is the donation and acceptance of an electron pair to form a new covalent bond. Lewis bases still must have an electron pair to donate, but Lewis acids-as electron-pair acceptors-include many species not encompassed by the other two definitions, including molecules with electron-deficient atoms or with polar double bonds, metal ions, and the proton itself.

## Section Summary

The Lewis acid-base definition focuses on the donation or acceptance of an electron pair to form a new covalent bond in an adduct, the product of an acid-base reaction. Lewis bases donate the electron pair, and Lewis acids accept it. • Thus, many species that do not contain H are Lewis acids. Molecules with polar double bonds act as Lewis acids, as do those with electron-deficient atoms. - Metal ions act as Lewis acids when they dissolve in water, which acts as a Lewis base, to form the adduct, a hydrated cation. - Many metal ions function as Lewis acids in biomolecules.

## Chapter Perspective

In this chapter, we extended the principles of equilibrium to acids and bases. We also investigated one direction in which the science of chemistry matured, as narrow definitions of acids and bases progressively widened to encompass different species, physical states, solvent systems, and reaction types. Acids and bases, by whatever definition, are an extremely important group of substances. In Chapter 19, we continue our discussion of acid-base behavior and apply many of the ideas developed here to other aqueous equilibria.

## CHAPTER REVIEW GUIDE The following sections provide many aids to help you study this chapter. (Numbers in parentheses refer to pages, unless noted otherwise.)

Learning Objectives These are concepts and skills you should know after studying this chapter.

Relevant section and/or sample problem (SP) numbers appear in parentheses.

## Understand These Concepts

1. Why the proton is bonded to a water molecule, as $\mathrm{H}_{3} \mathrm{O}^{+}$, in all aqueous acid-base systems (Section 18.1)
2. The Arrhenius definitions of an acid and a base (Section 18.1)
3. Why all reactions of a strong acid and a strong base have the same $\Delta H_{\mathrm{rxn}}^{\circ}$ (Section 18.1)
4. How the strength of an acid (or base) relates to the extent of its dissociation into ions in water (Section 18.1)
5. How relative acid strength is expressed by the acid-dissociation constant $K_{\mathrm{a}}$ (Section 18.1)
6. Why water is a very weak electrolyta and hoy its autoipnization is expressed by $K_{\mathrm{w}}$ (Section 18.2)
7. Why $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$is inversely related to $\left[\mathrm{OH}^{-}\right]$in any aqueous solution (Section 18.2)
8. How the relative magnitudes of $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$define whether a solution is acidic, basic, or neutral (Section 18.2)
9. The Brønsted-Lowry definitions of an acid and a base and how an acid-base reaction can be viewed as a proton-transfer process (Section 18.3)
10. How water acts as a base (or as an acid) when an acid (or a base) dissolves in it (Section 18.3)
11. How a conjugate acid-base pair differs by one proton (Section 18.3)
12. How a Brønsted-Lowry acid-base reaction involves two conjugate acid-base pairs (Section 18.3)
13. Why a stronger acid and base react $\left(K_{\mathrm{c}}>1\right)$ to form a weaker base and acid (Section 18.3)
14. How the percent dissociation of a weak acid increases as its concentration decreases (Section 18.4)
15. How a polyprotic acid dissociates in two or more steps and why only the first step supplies significant $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$(Section 18.4)
16. How weak bases in water accept a proton rather than dissociate; the meaning of $K_{\mathrm{b}}$ and $\mathrm{p} K_{\mathrm{b}}$ (Section 18.5)
17. How ammonia, amines, and weak-acid anions act as weak bases in water (Section 18.5)
18. Why relative concentrations of HA and $\mathrm{A}^{-}$determine the acidity or basicity of their solution (Section 18.5)
19. The relationship of the $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ of a conjugate acid-base pair to $K_{\mathrm{w}}$ (Section 18.5)
20. The effects of electronegativity, bond polarity, and bond strength on acid strength (Section 18.6)
21. Why aqueous solutions of small, highly charged metal ions are acidic (Section 18.6)
22. The various combinations of cations and anions that lead to acidic, basic, or neutral salt solutions (Section 18.7)
23. Why the strengths of strong acids are leveled in water but differentiated in a less basic solvent (Section 18.8)
24. The Lewis definitions of an acid and a base and how a Lewis acid-base reaction involves the donation and acceptance of an electron pair to form a covalent bond (Section 18.9)
25. How molecules with electron-deficient atoms, molecules with polar multiple bonds, and metal cations act as Lewis acids (Sec-

## Master These Skills

1. Classifying strong and weak acids and bases from their formulas (SP 18.1)
2. Using $K_{\mathrm{w}}$ to calculate $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$or $\left[\mathrm{OH}^{-}\right]$in an aqueous solution (SP 18.2)
3. Using p-scales to express $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right],\left[\mathrm{OH}^{-}\right]$, and $K$ (Section 18.2)
4. Calculating $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right], \mathrm{pH},\left[\mathrm{OH}^{-}\right]$, and $\mathrm{pOH}(\mathrm{SP}$ 18.3)
5. Identifying conjugate acid-base pairs (SP 18.4)
6. Using relative acid strengths to predict the net direction of an acid-base reaction (SPs 18.5, 18.6)
7. Calculating $K_{\mathrm{a}}$ of a weak acid from pH (SP 18.7)
8. Calculating $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$(and, thus, pH ) from $K_{\mathrm{a}}$ and $[\mathrm{HA}]_{\text {init }}$ (SP 18.8)
9. Applying the quadratic equation to find a concentration (Follow-up Problem 18.8)
10. Calculating the percent dissociation of a weak acid (Section 18.4 and SP 18.9)
11. Calculating $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and other concentrations for a polyprotic acid (SP 18.10)
12. Calculating pH from $K_{\mathrm{b}}$ and $[\mathrm{B}]_{\text {init }}$ (SP 18.11)
13. Finding $K_{\mathrm{b}}$ of $\mathrm{A}^{-}$from $K_{\mathrm{a}}$ of HA and $K_{\mathrm{w}}$ (Section 18.5 and SP 18.12)
14. Calculating pH from $K_{\mathrm{b}}$ of $\mathrm{A}^{-}$and $\left[\mathrm{A}^{-}\right]_{\text {init }}$ (SP 18.12)
15. Predicting relative acid strengths of nonmetal hydrides and oxoacids (Section 18.6)
16. Predicting the relative acidity of a salt solution from the nature of the cation and anion (SPs 18.13, 18.14)
17. Identifying Lewis acids and bases (SP 18.15)

Key Terms These important terms appear in boldface in the chapter and are defined again in the Glossary.

## Key Equations and Relationships Numbered and screened concepts are listed for you to refer to or memorize.

18.1 Defining the acid-dissociation constant (786):

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}
$$

18.2 Defining the ion-product constant for water (789):

$$
K_{\mathrm{w}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-14}\left(\text { at } 25^{\circ} \mathrm{C}\right)
$$

18.3 Defining pH (791):

$$
\mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]
$$

18.4 Relating $\mathrm{p} K_{\mathrm{w}}$ to pH and pOH (792):

$$
\mathrm{p} K_{\mathrm{w}}=\mathrm{pH}+\mathrm{pOH}=14.00\left(\text { at } 25^{\circ} \mathrm{C}\right)
$$

18.5 Finding the percent dissociation of HA (802):

$$
\text { Percent HA dissociated }=\frac{[\mathrm{HA}]_{\text {dissoc }}}{[\mathrm{HA}]_{\text {init }}} \times 100
$$

18.6 Defining the base-dissociation constant (805):

$$
K_{\mathrm{b}}=\frac{\left[\mathrm{BH}^{+}\right]\left[\mathrm{OH}^{-}\right]}{[\mathrm{B}]}
$$

18.7 Expressing the relationship among $K_{\mathrm{a}}, K_{\mathrm{b}}$, and $K_{\mathrm{w}}$ (809):

$$
K_{\mathrm{a}} \times K_{\mathrm{b}}=K_{\mathrm{w}}
$$

Highlighted Figures and Tables These figures (F) and tables (T) provide a visual review of key ideas.

Entries in bold contain frequently used data.
F18.1 Extent of dissociation for strong acids ( $\overline{785}$ )
F18.2 Extent of dissociation for weak acids (786)
F18.4 Relationship between $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$and relative acidity of solutions (790)
F18.6 Relations among $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right], \mathrm{pH},\left[\mathrm{OH}^{-}\right]$, and pOH (792)
F18.8 Proton transfer in Brønsted-Lowry acid-base reactions (794)

T18.4 Some conjugate acid-base pairs (795)
F18.9 Strengths of conjugate acid-base pairs (797)
F18.11 Effects of atomic and molecular properties on nonmetal hydride acidity (810)
F18.12 Relative strengths of oxoacids (811)
T18.8 Behavior of salts in water (815)

Brief Solutions to FOLLOW-UP PROBLEMS Compare your solutions to these calculation steps and answers.
18.1 (a) $\mathrm{HClO}_{3}$; (b) HCl ; (c) NaOH
$18.2\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\frac{1.0 \times 10^{-14}}{6.7 \times 10^{-2}}=1.5 \times 10^{-13} \mathrm{M}$; basic
$18.3 \mathrm{pOH}=14.00-9.52=4.48$
$\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-9.52}=3.0 \times 10^{-10} \mathrm{M}$
$\left[\mathrm{OH}^{-}\right]=\frac{1.0 \times 10^{-14}}{3.0 \times 10^{-10}}=3.3 \times 10^{-5} \mathrm{M}$
18.4 (a) $\mathrm{CH}_{3} \mathrm{COOH} / \mathrm{CH}_{3} \mathrm{COO}^{-}$and $\mathrm{H}_{3} \mathrm{O}^{+} / \mathrm{H}_{2} \mathrm{O}$
(b) $\mathrm{H}_{2} \mathrm{O} / \mathrm{OH}^{-}$and $\mathrm{HF} / \mathrm{F}^{-}$
$18.5(a) \mathrm{NH}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{4}{ }^{+}(a q)+\mathrm{OH}^{-}(a q)$
(b) $\mathrm{NH}_{3}(g)+\mathrm{H}_{3} \mathrm{O}^{+}(a q$; from HCl$) \longrightarrow \mathrm{NH}_{4}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$
(c) $\mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q$; from NaOH$) \longrightarrow \mathrm{NH}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l)$
18.6 There are more HB molecules than HA , so $K_{\mathrm{c}}>1$.
$18.7 \mathrm{NH}_{4}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{3}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)$
$\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-\mathrm{pH}}=10^{-5.0}=1 \times 10^{-5} \mathrm{M}=\left[\mathrm{NH}_{3}\right]$
From reaction table, $K_{\mathrm{a}}=\frac{\left[\mathrm{NH}_{3}\right]\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}{\left[\mathrm{NH}_{4}{ }^{+}\right]}=\frac{(x)(x)}{0.2-x}$

$$
\approx \frac{\left(1 \times 10^{-5}\right)^{2}}{0.2}=5 \times 10^{-10}
$$

$18.8 K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OCN}^{-}\right]}{[\mathrm{HOCN}]}=\frac{(x)(x)}{0.10-x}=3.5 \times 10^{-4}$
Since $\frac{[H O C N]_{\text {init }}}{K_{\mathrm{a}}}=\frac{0.10}{3.5 \times 10^{-4}}=286<400$, you must solve a quadratic equation: $x^{2}+\left(3.5 \times 10^{-4}\right) x-\left(3.5 \times 10^{-5}\right)=0$. $x=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=5.7 \times 10^{-3} \mathrm{M} ; \mathrm{pH}=2.24$
18.9 There is no single correct scene: any scene in which the total number of $\mathrm{HB}+\mathrm{H}_{3} \mathrm{O}^{+}$( or $\mathrm{HB}+\mathrm{B}^{-}$) is less than in the original solution, yet the number of HB dissociated is greater, would be correct. For example,

$18.10 K_{\mathrm{a} 1}=\frac{\left[\mathrm{HC}_{2} \mathrm{O}_{4}{ }^{-}\right]\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}{\left[\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right]}=\frac{x^{2}}{0.150-x}=5.6 \times 10^{-2}$
Since $\frac{\left[\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right]_{\text {init }}}{K_{\mathrm{a} 1}}<400$, you must solve a quadratic equation:
$x^{2}+\left(5.6 \times 10^{-2}\right) x-\left(8.4 \times 10^{-3}\right)=0$
$x=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=0.068 \mathrm{M} ; \mathrm{pH}=1.17$
$x=\left[\mathrm{HC}_{2} \mathrm{O}_{4}{ }^{-}\right]=0.068 \mathrm{M} ;\left[\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right]=0.150 \mathrm{M}-x=0.082 \mathrm{M}$
$\left[\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}\right]=\frac{\left(K_{\mathrm{a} 2}\right)\left[\mathrm{HC}_{2} \mathrm{O}_{4}^{-}\right]}{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}=\frac{\left(5.4 \times 10^{-5}\right)(0.068)}{0.068}$

$$
=5.4 \times 10^{-5} M
$$

$18.11 K_{\mathrm{b}}=\frac{\left[\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NH}^{+}\right]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\right]}=10^{-8.77}=1.7 \times 10^{-9}$
Assuming $0.10 M-x \approx 0.10 M, K_{\mathrm{b}}=1.7 \times 10^{-9} \approx \frac{(x)(x)}{0.10}$;
$x=\left[\mathrm{OH}^{-}\right] \approx 1.3 \times 10^{-5} \mathrm{M} ;\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=7.7 \times 10^{-10} \mathrm{M}$;
$\mathrm{pH}=9.11$
$18.12 K_{\mathrm{b}}$ of $\mathrm{ClO}^{-}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}} \text { of } \mathrm{HClO}}=\frac{1.0 \times 10^{-14}}{2.9 \times 10^{-8}}=3.4 \times 10^{-7}$
Assuming $0.20 M-x \approx 0.20 M$,
$K_{\mathrm{b}}=3.4 \times 10^{-7}=\frac{[\mathrm{HClO}]\left[\mathrm{OH}^{-}\right]}{\left[\mathrm{ClO}^{-}\right]} \approx \frac{x^{2}}{0.20} ;$
$x=\left[\mathrm{OH}^{-}\right] \approx 2.6 \times 10^{-4} \mathrm{M} ;\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=3.8 \times 10^{-11} \mathrm{M}$;
$\mathrm{pH}=10.42$
18.13 (a) Basic:

$$
\mathrm{ClO}_{2}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HCIO}(a q)+\mathrm{OH}^{-}(a q)
$$

$\mathrm{K}^{+}$is from strong base KOH .
(b) Acidic:
$\mathrm{CH}_{3} \mathrm{NH}_{3}{ }^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{CH}_{3} \mathrm{NH}_{2}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)$
$\mathrm{NO}_{3}{ }^{-}$is from strong acid $\mathrm{HNO}_{3}$.
(c) Neutral: $\mathrm{Cs}^{+}$is from strong base $\mathrm{CsOH} ; \mathrm{I}^{-}$is from strong acid HI.
18.14 (a) $K_{\mathrm{a}}$ of $\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}=3 \times 10^{-8}$
$K_{\mathrm{b}}$ of $\mathrm{CH}_{3} \mathrm{COO}^{-}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}} \text { of } \mathrm{CH}_{3} \mathrm{COOH}}=5.6 \times 10^{-10}$
Since $K_{\mathrm{a}}>K_{\mathrm{b}}, \mathrm{Cu}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2}(a q)$ is acidic.
(b) $K_{\mathrm{a}}$ of $\mathrm{NH}_{4}^{+}=\frac{K_{\mathrm{w}}}{K_{\mathrm{b}} \text { of } \mathrm{NH}_{3}}=5.7 \times 10^{-10}$
$K_{\mathrm{b}}$ of $\mathrm{F}^{-}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}} \text { of } \mathrm{HF}}=1.5 \times 10^{-11}$
Because $K_{\mathrm{a}}>K_{\mathrm{b}}, \mathrm{NH}_{4} \mathrm{~F}(\mathrm{aq})$ is acidic.
(c) From Appendix C, $K_{\mathrm{a}}$ of $\mathrm{HSO}_{3}^{-}=6.5 \times 10^{-8}$
$K_{\mathrm{b}}$ of $\mathrm{HSO}_{3}^{-}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}} \text { of } \mathrm{H}_{2} \mathrm{SO}_{3}}=7.1 \times 10^{-13}$
Because $K_{\mathrm{a}}>K_{\mathrm{b}}, \mathrm{KHSO}_{3}(a q)$ is acidic
18.15 (a) $\mathrm{OH}^{-}$is the Lewis base; $\mathrm{Al}(\mathrm{OH})_{3}$ is the Lewis acid.
(b) $\mathrm{H}_{2} \mathrm{O}$ is the Lewis base; $\mathrm{SO}_{3}$ is the Lewis acid.
(c) $\mathrm{NH}_{3}$ is the Lewis base; $\mathrm{Co}^{3+}$ is the Lewis acid.

## PROBLEMS

Problems with colored numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and provide the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.
Note: Unless stated otherwise, all problems refer to aqueous solutions at $298 \mathrm{~K}\left(25^{\circ} \mathrm{C}\right)$.

## Acids and Bases in Water

(Sample Problem 18.1)

## - Concept Review Questions

18.1 What is the role of water in the Arrhenius acid-base definition? 18.2 What do Arrhenius acids have in common? What do Arrhenius bases have in common? Explain neutralization in terms of the Arrhenius acid-base definition. What data led Arrhenius to propose this idea of neutralization?
18.3 Why is the Arrhenius acid-base definition too limited? Give an example for which the Arrhenius definition does not apply.
18.4 What do "strong" and "weak" mean for acids and bases? $K_{\mathrm{a}}$ values of weak acids vary over more than 10 orders of magnitude. What do the acids have in common that makes them "weak"?

## Skill-Building Exercises (grouped in similar pairs)

18.5 Which of the following are Arrhenius acids?
(a) $\mathrm{H}_{2} \mathrm{O}$
(b) $\mathrm{Ca}(\mathrm{OH})_{2}$
(c) $\mathrm{H}_{3} \mathrm{PO}_{3}$
(d) HI
18.6 Which of the following are Arrhenius acids?
(a) $\mathrm{NaHSO}_{4}$
(b) $\mathrm{CH}_{4}$
(c) NaH
(d) $\mathrm{H}_{3} \mathrm{~N}$
18.7 Which of the following are Arrhenius bases?
(a) $\mathrm{H}_{3} \mathrm{AsO}_{4}$
(b) $\mathrm{Ba}(\mathrm{OH})_{2}$
(c) HClO
(d) KOH
18.8 Which of the following are Arrhenius bases?
(a) $\mathrm{CH}_{3} \mathrm{COOH}$
(b) HOH
(c) $\mathrm{CH}_{3} \mathrm{OH}$
(d) $\mathrm{H}_{2} \mathrm{NNH}_{2}$
18.9 Write the $K_{\mathrm{a}}$ expression for each of the following in water:
(a) HCN
(b) $\mathrm{HCO}_{3}{ }^{-}$
(c) HCOOH
18.10 Write the $K_{\mathrm{a}}$ expression for each of the following in water:
(a) $\mathrm{CH}_{3} \mathrm{NH}_{3}{ }^{+}$
(b) HClO
(c) $\mathrm{H}_{2} \mathrm{~S}$
18.11 Write the $K_{\mathrm{a}}$ expression for each of the following in water:
(a) $\mathrm{HNO}_{2}$
(b) $\mathrm{CH}_{3} \mathrm{COOH}$
(c) $\mathrm{HBrO}_{2}$
18.12 Write the $K_{\mathrm{a}}$ expression for each of the following in water:
(a) $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}$
(b) $\mathrm{H}_{3} \mathrm{PO}_{2}$
(c) $\mathrm{HSO}_{4}{ }^{-}$
18.13 Use Appendix C to rank the following in order of increasing acid strength: $\mathrm{HIO}_{3}, \mathrm{HI}, \mathrm{CH}_{3} \mathrm{COOH}, \mathrm{HF}$.
18.14 Use Appendix C to rank the following in order of decreasing acid strength: $\mathrm{HClO}, \mathrm{HCl}, \mathrm{HCN}, \mathrm{HNO}_{2}$.
18.15 Classify each as a strong or weak acid or base:
(a) $\mathrm{H}_{3} \mathrm{AsO}_{4}$
(b) $\mathrm{Sr}(\mathrm{OH})_{2}$
(c) HIO
(d) $\mathrm{HClO}_{4}$
18.16 Classify each as a strong or weak acid or base:
(a) $\mathrm{CH}_{3} \mathrm{NH}_{2}$
(b) $\mathrm{K}_{2} \mathrm{O}$
(c) HI
(d) HCOOH
18.17 Classify each as a strong or weak acid or base:
(a) RbOH
(b) HBr
(c) $\mathrm{H}_{2} \mathrm{Te}$
(d) HClO
18.18 Classify each as a strong or weak acid or base:
(a) $\mathrm{HOCH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}$
(b) $\mathrm{H}_{2} \mathrm{SeO}_{4}$
(c) $\mathrm{HS}^{-}$
(d) $\mathrm{B}(\mathrm{OH})_{3}$

## Autoionization of Water and the pH Scale

(Sample Problems 18.2 and 18.3)

## - Concept Review Questions

18.19 What is an autoionization reaction? Write equations for the autoionization reactions of $\mathrm{H}_{2} \mathrm{O}$ and of $\mathrm{H}_{2} \mathrm{SO}_{4}$.
18.20 What is the difference between $K_{\mathrm{c}}$ and $K_{\mathrm{w}}$ for the autoionization of water?
18.21 (a) What is the change in pH when $\left[\mathrm{OH}^{-}\right]$increases by a factor of 10 ? (b) What is the change in $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$when the pH decreases by 3 units?
18.22 Which solution has the higher pH ? Explain.
(a) A $0.1 M$ solution of an acid with $K_{\mathrm{a}}=1 \times 10^{-4}$ or one with $K_{\mathrm{a}}=4 \times 10^{-5}$
(b) A $0.1 M$ solution of an acid with $\mathrm{p} K_{\mathrm{a}}=3.0$ or one with $\mathrm{p} K_{\mathrm{a}}=3.5$
(c) A 0.1 M solution or a 0.01 M solution of a weak acid
(d) A 0.1 M solution of a weak acid or a 0.1 M solution of a strong acid
(e) A $0.1 M$ solution of an acid or a $0.01 M$ solution of a base
(f) A solution of pOH 6.0 or one of pOH 8.0

Skill-Building Exercises (grouped in similar pairs)
18.23 (a) What is the pH of 0.0111 M NaOH ? Is the solution neutral, acidic, or basic? (b) What is the pOH of $1.35 \times 10^{-3} \mathrm{M} \mathrm{HCl}$ ? Is the solution neutral, acidic, or basic?
18.24 (a) What is the pH of $0.0333 \mathrm{M} \mathrm{HNO}_{3}$ ? Is the solution neutral, acidic, or basic? (b) What is the pOH of 0.0347 M KOH ? Is the solution neutral, acidic, or basic?
18.25 (a) What is the pH of $6.14 \times 10^{-3} \mathrm{M} \mathrm{HI}$ ? Is the solution neutral, acidic, or basic? (b) What is the pOH omes5deatohl? Is the solution neutral, acidic, or basic?
18.26 (a) What is the pH of $7.52 \times 10^{-4} \mathrm{M} \mathrm{CsOH}$ ? Is the solution neutral, acidic, or basic? (b) What is the pOH of $1.59 \times 10^{-3} \mathrm{M}$ $\mathrm{HClO}_{4}$ ? Is the solution neutral, acidic, or basic?
18.27 (a) What are $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right],\left[\mathrm{OH}^{-}\right]$, and pOH in a solution with a pH of 9.85 ? (b) What are $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right],\left[\mathrm{OH}^{-}\right]$, and pH in a solution with a pOH of 9.43 ?
18.28 (a) What are $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right],\left[\mathrm{OH}^{-}\right]$, and pOH in a solution with a pH of 3.47 ? (b) What are $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right],\left[\mathrm{OH}^{-}\right]$, and pH in a solution with a pOH of 4.33 ?
18.29 (a) What are $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right],\left[\mathrm{OH}^{-}\right]$, and pOH in a solution with a pH of 4.77 ? (b) What are $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right],\left[\mathrm{OH}^{-}\right]$, and pH in a solution with a pOH of 5.65 ?
18.30 (a) What are $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right],\left[\mathrm{OH}^{-}\right]$, and pOH in a solution with a pH of 8.97 ? (b) What are $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right],\left[\mathrm{OH}^{-}\right]$, and pH in a solution with a pOH of 11.27 ?
18.31 How many moles of $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$must you add per liter of HA solution to adjust its pH from 3.15 to 3.65? Assume a negligible volume change.
18.32 How many moles of $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$must you add per liter of HA solution to adjust its pH from 9.33 to 9.07? Assume a negligible volume change.
18.33 How many moles of $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$must you add to 5.6 L of HA solution to adjust its pH from 4.52 to 5.25 ? Assume a negligible volume change.
18.34 How many moles of $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$must you add to 87.5 mL of HA solution to adjust its pH from 8.92 to 6.33 ? Assume a negligible volume change.

## Problems in Context

18.35 The two molecular scenes below depict the relative concentrations of $\mathrm{H}_{3} \mathrm{O}^{+}$(purple) in solutions of the same volume (with counter ions and solvent molecules omitted for clarity). If the pH in scene A is 4.8 , what is the pH in scene B ?

18.36 Like any equilibrium constant, $K_{\mathrm{w}}$ changes with temperature. (a) Given that autoionization is endothermic, how does $K_{\mathrm{w}}$ change with rising $T$ ? Explain with a reaction that includes heat as reactant or product. (b) In many medical applications, the value of $K_{\mathrm{w}}$ at $37^{\circ} \mathrm{C}$ (body temperature) may be more appropriate than the value at $25^{\circ} \mathrm{C}, 1.0 \times 10^{-14}$. The pH of pure water at $37^{\circ} \mathrm{C}$ is 6.80. Calculate $K_{\mathrm{w}}, \mathrm{pOH}$, and $\left[\mathrm{OH}^{-}\right]$at this temperature.

## Proton Transfer and the Brønsted-Lowry Acid-Base Definition

(Sample Problems 18.4 to 18.6)

## Concept Review Questions

18.37 How are the Arrhenius and Brønsted-Lowry acid-base definitions different? How are they similar? Name two BrønstedLowry bases that are not Arrhenius bases. Can you do the same foracids? Explain?
18.38 What is a conjugate acid-base pair? What is the relationship between the two members of the pair?
18.39 (a) A Brønsted-Lowry acid-base reaction proceeds in the net direction in which a stronger acid and stronger base form a weaker acid and weaker base. Explain.
(b) The molecular scene at right depicts an aqueous solution of two conjugate acid-base pairs: $\mathrm{HA} / \mathrm{A}^{-}$and $\mathrm{HB} / \mathrm{B}^{-}$. The base in the first pair is represented by red spheres and the base in the second pair by green spheres; solvent molecules are omitted for clarity. Which is the stronger acid? Stronger base? Explain.

18.40 What is an amphiprotic species? Name one and write balanced equations that show why it is amphiprotic.

## Skill-Building Exercises (grouped in similar pairs)

18.41 Write balanced equations and $K_{\mathrm{a}}$ expressions for these Brønsted-Lowry acids in water:
(a) $\mathrm{H}_{3} \mathrm{PO}_{4}$
(b) $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}$
(c) $\mathrm{HSO}_{4}^{-}$
18.42 Write balanced equations and $K_{\mathrm{a}}$ expressions for these Brønsted-Lowry acids in water:
(a) HCOOH
(b) $\mathrm{HClO}_{3}$
(c) $\mathrm{H}_{2} \mathrm{AsO}_{4}^{-}$
18.43 Give the formula of the conjugate base:
(a) HCl
(b) $\mathrm{H}_{2} \mathrm{CO}_{3}$
(c) $\mathrm{H}_{2} \mathrm{O}$
18.44 Give the formula of the conjugate base:
(a) $\mathrm{HPO}_{4}{ }^{2-}$
(b) $\mathrm{NH}_{4}{ }^{+}$
(c) $\mathrm{HS}^{-}$
18.45 Give the formula of the conjugate acid:
(a) $\mathrm{NH}_{3}$
(b) $\mathrm{NH}_{2}{ }^{-}$
(c) nicotine, $\mathrm{C}_{10} \mathrm{H}_{14} \mathrm{~N}_{2}$
18.46 Give the formula of the conjugate acid:
(a) $\mathrm{O}^{2-}$
(b) $\mathrm{SO}_{4}{ }^{2-}$
(c) $\mathrm{H}_{2} \mathrm{O}$
18.47 In each equation, label the acids, bases, and conjugate pairs:
(a) $\mathrm{HCl}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{Cl}^{-}+\mathrm{H}_{3} \mathrm{O}^{+}$
(b) $\mathrm{HClO}_{4}+\mathrm{H}_{2} \mathrm{SO}_{4} \rightleftharpoons \mathrm{ClO}_{4}^{-}+\mathrm{H}_{3} \mathrm{SO}_{4}^{+}$
(c) $\mathrm{HPO}_{4}^{2-}+\mathrm{H}_{2} \mathrm{SO}_{4} \rightleftharpoons \mathrm{H}_{2} \mathrm{PO}_{4}^{-}+\mathrm{HSO}_{4}^{-}$
18.48 In each equation, label the acids, bases, and conjugate pairs:
(a) $\mathrm{NH}_{3}+\mathrm{HNO}_{3} \rightleftharpoons \mathrm{NH}_{4}{ }^{+}+\mathrm{NO}_{3}{ }^{-}$
(b) $\mathrm{O}^{2-}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{OH}^{-}+\mathrm{OH}^{-}$
(c) $\mathrm{NH}_{4}^{+}+\mathrm{BrO}_{3}^{-} \rightleftharpoons \mathrm{NH}_{3}+\mathrm{HBrO}_{3}$
18.49 In each equation, label the acids, bases, and conjugate pairs:
(a) $\mathrm{NH}_{3}+\mathrm{H}_{3} \mathrm{PO}_{4} \rightleftharpoons \mathrm{NH}_{4}^{+}+\mathrm{H}_{2} \mathrm{PO}_{4}^{-}$
(b) $\mathrm{CH}_{3} \mathrm{O}^{-}+\mathrm{NH}_{3} \rightleftharpoons \mathrm{CH}_{3} \mathrm{OH}+\mathrm{NH}_{2}^{-}$
(c) $\mathrm{HPO}_{4}^{2-}+\mathrm{HSO}_{4}^{-} \rightleftharpoons \mathrm{H}_{2} \mathrm{PO}_{4}^{-}+\mathrm{SO}_{4}^{2-}$
18.50 In each equation, label the acids, bases, and conjugate pairs:
(a) $\mathrm{NH}_{4}^{+}+\mathrm{CN}^{-} \rightleftharpoons \mathrm{NH}_{3}+\mathrm{HCN}$
(b) $\mathrm{H}_{2} \mathrm{O}+\mathrm{HS}^{-} \rightleftharpoons \mathrm{OH}^{-}+\mathrm{H}_{2} \mathrm{~S}$
(c) $\mathrm{HSO}_{3}^{-}+\mathrm{CH}_{3} \mathrm{NH}_{2} \rightleftharpoons \mathrm{SO}_{3}^{2-}+\mathrm{CH}_{3} \mathrm{NH}_{3}^{+}$
18.51 Write balanced net ionic equations for the following reactions, and label the conjugate acid-base pairs:
(a) $\mathrm{NaOH}(a q)+\mathrm{NaH}_{2} \mathrm{PO}_{4}(a q) \rightleftharpoons \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Na}_{2} \mathrm{HPO}_{4}(a q)$
(b) $\mathrm{KHSO}_{4}(a q)+\mathrm{K}_{2} \mathrm{CO}_{3}(a q) \rightleftharpoons \mathrm{K}_{2} \mathrm{SO}_{4}(a q)+\mathrm{KHCO}_{3}(a q)$
18.52 Write balanced net ionic equations for the following reactions, and label the conjugate acid-base pairs:
(a) $\mathrm{HNO}_{3}(a q)+\mathrm{Li}_{2} \mathrm{CO}_{3}(a q) \rightleftharpoons \mathrm{LiNO}_{3}(a q)+\mathrm{LiHCO}_{3}(a q)$
(b) $2 \mathrm{NH}_{4} \mathrm{Cl}(a q)+\mathrm{Ba}(\mathrm{OH})_{2}(a q) \rightleftharpoons$
$2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{BaCl}_{2}(a q)+2 \mathrm{NH}_{3}(a q)$
18.53 The following aqueous species ponstitute tyo conjugate acid-base pairs. Use them to write one acid-base reaction with $K_{\mathrm{c}}>1$ and another with $K_{\mathrm{c}}<1$ : $\mathrm{HS}^{-}, \mathrm{Cl}^{-}, \mathrm{HCl}, \mathrm{H}_{2} \mathrm{~S}$.
18.54 The following aqueous species constitute two conjugate acid-base pairs. Use them to write one acid-base reaction with $K_{\mathrm{c}}>1$ and another with $K_{\mathrm{c}}<1: \mathrm{NO}_{3}{ }^{-}, \mathrm{F}^{-}, \mathrm{HF}, \mathrm{HNO}_{3}$.
18.55 Use Figure 18.9 (p. 797) to determine whether $K_{\mathrm{c}}>1$ for
(a) $\mathrm{HCl}+\mathrm{NH}_{3} \rightleftharpoons \mathrm{NH}_{4}^{+}+\mathrm{Cl}^{-}$
(b) $\mathrm{H}_{2} \mathrm{SO}_{3}+\mathrm{NH}_{3} \rightleftharpoons \mathrm{HSO}_{3}^{-}+\mathrm{NH}_{4}^{+}$
18.56 Use Figure 18.9 (p. 797) to determine whether $K_{\mathrm{c}}>1$ for
(a) $\mathrm{OH}^{-}+\mathrm{HS}^{-} \rightleftharpoons \mathrm{H}_{2} \mathrm{O}+\mathrm{S}^{2-}$
(b) $\mathrm{HCN}+\mathrm{HCO}_{3}^{-} \rightleftharpoons \mathrm{H}_{2} \mathrm{CO}_{3}+\mathrm{CN}^{-}$
18.57 Use Figure 18.9 (p. 797) to determine whether $K_{\mathrm{c}}<1$ for
(a) $\mathrm{NH}_{4}^{+}+\mathrm{HPO}_{4}{ }^{2-} \rightleftharpoons \mathrm{NH}_{3}+\mathrm{H}_{2} \mathrm{PO}_{4}^{-}$
(b) $\mathrm{HSO}_{3}^{-}+\mathrm{HS}^{-} \rightleftharpoons \mathrm{H}_{2} \mathrm{SO}_{3}+\mathrm{S}^{2-}$
18.58 Use Figure 18.9 (p. 797) to determine whether $K_{\mathrm{c}}<1$ for
(a) $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}+\mathrm{F}^{-} \rightleftharpoons \mathrm{HPO}_{4}^{2-}+\mathrm{HF}$
(b) $\mathrm{CH}_{3} \mathrm{COO}^{-}+\mathrm{HSO}_{4}^{-} \rightleftharpoons \mathrm{CH}_{3} \mathrm{COOH}+\mathrm{SO}_{4}{ }^{2-}$

## Solving Problems Involving Weak-Acid Equilibria

(Sample Problems 18.7 to 18.10)

## - Concept Review Questions

18.59 In each of the following cases, is the concentration of acid before and after dissociation nearly the same or very different? Explain your reasoning: (a) a concentrated solution of a strong acid; (b) a concentrated solution of a weak acid; (c) a dilute solution of a weak acid; (d) a dilute solution of a strong acid.
18.60 A sample of 0.0001 M HCl has $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$close to that of a sample of 0.1 MCH COOH . Are acetic acid and hydrochloric acid equally strong in these samples? Explain.
18.61 In which of the following solutions will $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$be approximately equal to $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]$: (a) $0.1 \mathrm{M} \mathrm{CH} 3 \mathrm{COOH}^{2}$; (b) $1 \times 10^{-7} \mathrm{M} \mathrm{CH}_{3} \mathrm{COOH}$; (c) a solution containing both 0.1 M $\mathrm{CH}_{3} \mathrm{COOH}$ and 0.1 M CH 3 COONa? Explain.
18.62 Why do successive $K_{\mathrm{a}}$ 's decrease for all polyprotic acids?

## Skill-Building Exercises (grouped in similar pairs)

18.63 A 0.15 M solution of butanoic acid, $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{COOH}$, contains $1.51 \times 10^{-3} M \mathrm{H}_{3} \mathrm{O}^{+}$. What is the $K_{\mathrm{a}}$ of butanoic acid?
18.64 A 0.035 M solution of a weak acid (HA) has a pH of 4.88 . What is the $K_{\mathrm{a}}$ of the acid?
18.65 Nitrous acid, $\mathrm{HNO}_{2}$, has a $K_{\mathrm{a}}$ of $7.1 \times 10^{-4}$. What are $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right],\left[\mathrm{NO}_{2}{ }^{-}\right]$, and $\left[\mathrm{OH}^{-}\right]$in 0.60 M HNO 2 ?
18.66 Hydrofluoric acid, HF, has a $K_{\mathrm{a}}$ of $6.8 \times 10^{-4}$. What are $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right],\left[\mathrm{F}^{-}\right]$, and $\left[\mathrm{OH}^{-}\right]$in 0.75 M HF ?
18.67 Chloroacetic acid, $\mathrm{ClCH}_{2} \mathrm{COOH}$, has a $\mathrm{p} K_{\mathrm{a}}$ of 2.87. What are $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right], \mathrm{pH},\left[\mathrm{ClCH}_{2} \mathrm{COO}^{-}\right]$, and $\left[\mathrm{ClCH}_{2} \mathrm{COOH}\right]$ in 1.25 M $\mathrm{ClCH}_{2} \mathrm{COOH}$ ?
18.68 Hypochlorous acid, HClO , has a $\mathrm{p} K_{\mathrm{a}}$ of 7.54 . What are $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right], \mathrm{pH},\left[\mathrm{ClO}^{-}\right]$, and $[\mathrm{HClO}]$ in 0.115 M HClO ?
18.69 In a 0.20 M solution, a weak acid is $3.0 \%$ dissociated.
(a) Calculate the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right], \mathrm{pH},\left[\mathrm{OH}^{-}\right]$, and pOH of the solution.
(b) Calculate $K_{\mathrm{a}}$ of the acid.
18.70 In a $0.735 M$ solution, a weak acid is $12.5 \%$ dissociated.
(a) Calculate the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right], \mathrm{pH},\left[\mathrm{OH}^{-}\right]$, and pOH of the solution.
(b) Calculate $K_{\mathrm{a}}$ of the acid.
18.71 A $0.250-\mathrm{mol}$ sample of HX is dissolved in enough $\mathrm{H}_{2} \mathrm{O}$ to form 655 mL of solution. If the pH of the solution is 3.54 , what Fnisthenofye?
18.72 A $4.85 \times 10^{-3}-\mathrm{mol}$ sample of HY is dissolved in enough $\mathrm{H}_{2} \mathrm{O}$ to form 0.095 L of solution. If the pH of the solution is 2.68 , what is the $K_{\mathrm{a}}$ of HY?
18.73 The weak acid HZ has a $K_{\mathrm{a}}$ of $2.55 \times 10^{-4}$.
(a) Calculate the pH of 0.075 M HZ .
(b) Calculate the pOH of 0.045 M HZ .
18.74 The weak acid HQ has a $\mathrm{p} K_{\mathrm{a}}$ of 4.89 .
(a) Calculate the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$of $3.5 \times 10^{-2} \mathrm{M} \mathrm{HQ}$.
(b) Calculate the $\left[\mathrm{OH}^{-}\right]$of 0.65 M HQ .
18.75 (a) Calculate the pH of 0.175 M HY , if $K_{\mathrm{a}}=1.50 \times 10^{-4}$.
(b) Calculate the pOH of 0.175 M HX , if $K_{\mathrm{a}}=2.00 \times 10^{-2}$.
18.76 (a) Calculate the pH of 0.55 M HCN , if $K_{\mathrm{a}}=6.2 \times 10^{-10}$.
(b) Calculate the pOH of $0.044 \mathrm{M} \mathrm{HIO}_{3}$, if $K_{\mathrm{a}}=0.16$.
18.77 Use Appendix C to calculate the percent dissociation of 0.55 M benzoic acid, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}$.
18.78 Use Appendix C to calculate the percent dissociation of $0.050 \mathrm{M} \mathrm{CH}_{3} \mathrm{COOH}$.
18.79 Use Appendix C to calculate $\left[\mathrm{H}_{2} \mathrm{~S}\right],\left[\mathrm{HS}^{-}\right],\left[\mathrm{S}^{2-}\right],\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$, $\mathrm{pH},\left[\mathrm{OH}^{-}\right]$, and pOH in a 0.10 M solution of the diprotic acid hydrosulfuric acid.
18.80 Use Appendix C to calculate $\left[\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right],\left[\mathrm{HC}_{2} \mathrm{O}_{4}{ }^{-}\right]$, $\left[\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}\right],\left[\mathrm{H}_{3} \mathrm{O}^{+}\right], \mathrm{pH},\left[\mathrm{OH}^{-}\right]$, and pOH in a 0.200 M solution of the diprotic acid oxalic acid.

## - Problems in Context

18.81 Acetylsalicylic acid (aspirin), $\mathrm{HC}_{9} \mathrm{H}_{7} \mathrm{O}_{4}$, is the most widely used pain reliever and fever reducer. Find the pH of 0.018 M aqueous aspirin at body temperature ( $K_{\mathrm{a}}$ at $37^{\circ} \mathrm{C}=3.6 \times 10^{-4}$ ).
18.82 Formic acid, HCOOH , the simplest carboxylic acid, is used in the textile and rubber industries and is secreted as a defense by many species of ants (family Formicidae). Calculate the percent dissociation of 0.75 M HCOOH .

## Weak Bases and Their Relation to Weak Acids <br> (Sample Problems 18.11 and 18.12)

## - Concept Review Questions

18.83 What is the key structural feature of all Brønsted-Lowry bases? How does this feature function in an acid-base reaction?
18.84 Why are most anions basic in $\mathrm{H}_{2} \mathrm{O}$ ? Give formulas of four anions that are not basic.
18.85 Except for the $\mathrm{Na}^{+}$spectator ion, aqueous solutions of $\mathrm{CH}_{3} \mathrm{COOH}$ and $\mathrm{CH}_{3} \mathrm{COONa}$ contain the same species. (a) What are the species (other than $\mathrm{H}_{2} \mathrm{O}$ )? (b) Why is $0.1 \mathrm{M} \mathrm{CH}_{3} \mathrm{COOH}$ acidic and $0.1 \mathrm{M} \mathrm{CH}_{3} \mathrm{COONa}$ basic?

- Skill-Building Exercises (grouped in similar pairs)
18.86 Write balanced equations and $K_{\mathrm{b}}$ expressions for these Brønsted-Lowry bases in water:
(a) Pyridine, $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}$
(b) $\mathrm{CO}_{3}{ }^{2-}$
18.87 Write balanced equations and $K_{\mathrm{b}}$ expressions for these Brønsted-Lowry bases in water:
(a) Benzoate ion, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}$
(b) $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{~N}$
18.88 Write balanced equations and $K_{\mathrm{b}}$ expressions for these Brønsted-Lowry bases in water:
(a) Hydroxylamine, $\mathrm{HO}-\mathrm{NH}_{2}$
(b) $\mathrm{HPO}_{4}{ }^{2-}$
18.89 Write balanced equations and $K_{\mathrm{b}}$ expressions for these Brønsted-Lowry bases in water: Apago P.
(a) Guanidine, $\left(\mathrm{H}_{2} \mathrm{~N}\right)_{2} \mathrm{C}=\mathrm{NH}$ (double-bonded N is most basic)
(b) Acetylide ion, $\mathrm{HC} \equiv \mathrm{C}^{-}$
18.90 What is the pH of 0.070 M dimethylamine?
18.91 What is the pH of 0.12 M diethylamine?
18.92 What is the pH of 0.25 M ethanolamine?
18.93 What is the pH of 0.26 M aniline?
18.94 (a) What is the $K_{\mathrm{b}}$ of the acetate ion?
(b) What is the $K_{\mathrm{a}}$ of the anilinium ion, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3}{ }^{+}$?
18.95 (a) What is the $K_{\mathrm{b}}$ of the benzoate ion, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}$?
(b) What is the $K_{\mathrm{a}}$ of the 2-hydroxyethylammonium ion, $\mathrm{HOCH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{3}{ }^{+}\left(\mathrm{p} K_{\mathrm{b}}\right.$ of $\left.\mathrm{HOCH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}=4.49\right)$ ?
18.96 (a) What is the $\mathrm{p} K_{\mathrm{b}}$ of $\mathrm{ClO}_{2}{ }^{-}$?
(b) What is the $\mathrm{p} K_{\mathrm{a}}$ of the dimethylammonium ion, $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}_{2}{ }^{+}$?
18.97 (a) What is the $\mathrm{p} K_{\mathrm{b}}$ of $\mathrm{NO}_{2}^{-}$?
(b) What is the $\mathrm{p} K_{\mathrm{a}}$ of the hydrazinium ion, $\mathrm{H}_{2} \mathrm{~N}-\mathrm{NH}_{3}{ }^{+}$ $\left(K_{\mathrm{b}}\right.$ of hydrazine $\left.=8.5 \times 10^{-7}\right)$ ?
18.98 (a) What is the pH of 0.150 MKCN ?
(b) What is the pH of 0.40 M triethylammonium chloride, $\left(\mathrm{CH}_{3} \mathrm{CH}_{2}\right)_{3} \mathrm{NHCl}$ ?
18.99 (a) What is the pH of 0.100 M sodium phenolate, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{ONa}$, the sodium salt of phenol?
(b) What is the pH of 0.15 M methylammonium bromide, $\mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{Br}\left(K_{\mathrm{b}}\right.$ of $\left.\mathrm{CH}_{3} \mathrm{NH}_{2}=4.4 \times 10^{-4}\right)$ ?
18.100 (a) What is the pH of 0.65 M potassium formate, HCOOK?
(b) What is the pH of $0.85 \mathrm{M} \mathrm{NH}_{4} \mathrm{Br}$ ?
18.101 (a) What is the pH of 0.75 M NaF ?
(b) What is the pH of 0.88 M pyridinium chloride, $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NHCl}$ ?

## Problems in Context

18.102 Sodium hypochlorite solution, sold as "chlorine bleach," is potentially dangerous because of the basicity of $\mathrm{ClO}^{-}$, the active bleaching ingredient. What is $\left[\mathrm{OH}^{-}\right]$in an aqueous solution that is $6.5 \% \mathrm{NaClO}$ by mass? What is the pH of the solution? (Assume $d$ of solution $=1.0 \mathrm{~g} / \mathrm{mL}$.)
18.103 Codeine $\left(\mathrm{C}_{18} \mathrm{H}_{21} \mathrm{NO}_{3}\right)$ is a narcotic pain reliever that forms a salt with HCl . What is the pH of 0.050 M codeine hydrochloride $\left(\mathrm{p} K_{\mathrm{b}}\right.$ of codeine $\left.=5.80\right)$ ?

## Molecular Properties and Acid Strength

## - Concept Review Questions

18.104 Across a period, how does the electronegativity of a nonmetal affect the acidity of its binary hydride?
18.105 How does the atomic size of a nonmetal affect the acidity of its binary hydride?
18.106 A strong acid has a weak bond to its acidic proton, whereas a weak acid has a strong bond to its acidic proton. Explain.
18.107 Perchloric acid, $\mathrm{HClO}_{4}$, is the strongest of the halogen oxoacids, and hypoiodous acid, HIO, is the weakest. What two factors govern this difference in acid strength?

## Skill-Building Exercises (grouped in similar pairs)

18.108 Choose the stronger acid in each of the following pairs:
(a) $\mathrm{H}_{2} \mathrm{SeO}_{3}$ or $\mathrm{H}_{2} \mathrm{SeO}_{4}$
(b) $\mathrm{H}_{3} \mathrm{PO}_{4}$ or $\mathrm{H}_{3} \mathrm{AsO}_{4}$
(c) $\mathrm{H}_{2} \mathrm{~S}$ or $\mathrm{H}_{2} \mathrm{Te}$ 18.109 Choose the weaker acid in each of the following pairs:
(a) HBr or $\mathrm{H}_{2} \mathrm{Se}$
(b) $\mathrm{HClO}_{4}$ or $\mathrm{H}_{2} \mathrm{SO}_{4}$
(c) $\mathrm{H}_{2} \mathrm{SO}_{3}$ or $\mathrm{H}_{2} \mathrm{SO}_{4}$
18.110 Choose the stronger acid in each of the following pairs:
(a) $\mathrm{H}_{2} \mathrm{Se}$ or $\mathrm{H}_{3} \mathrm{As}$
(b) $\mathrm{B}(\mathrm{OH})_{3}$ or $\mathrm{Al}(\mathrm{OH})_{3}$
(c) $\mathrm{HBrO}_{2}$ or HBrO
(a) HI or HBr
(b) $\mathrm{H}_{3} \mathrm{AsO}_{4}$ or $\mathrm{H}_{2} \mathrm{SeO}_{4}$
(c) $\mathrm{HNO}_{3}$ or $\mathrm{HNO}_{2}$
18.112 Use Appendix C to choose the solution with the lower pH :
(a) $0.5 \mathrm{M} \mathrm{CuSO}_{4}$ or $0.25 \mathrm{M} \mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}$
(b) 0.3 M ZnCl 2 or $0.3 ~ M \mathrm{PbCl}_{2}$
18.113 Use Appendix C to choose the solution with the lower pH :
(a) $0.1 \mathrm{M} \mathrm{FeCl}_{3}$ or $0.1 \mathrm{M} \mathrm{AlCl}_{3}$
(b) $0.1 \mathrm{M} \mathrm{BeCl}_{2}$ or $0.1 \mathrm{M} \mathrm{CaCl}_{2}$
18.114 Use Appendix C to choose the solution with the higher pH :
(a) $0.2 \mathrm{M} \mathrm{Ni}\left(\mathrm{NO}_{3}\right)_{2}$ or $0.2 \mathrm{M} \mathrm{Co}\left(\mathrm{NO}_{3}\right)_{2}$
(b) $0.35 \mathrm{M} \mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}$ or $0.35 \mathrm{M} \mathrm{Cr}\left(\mathrm{NO}_{3}\right)_{3}$
18.115 Use Appendix C to choose the solution with the higher pH :
(a) 0.1 M NiCl 2 or 0.1 M NaCl
(b) $0.1 \mathrm{M} \mathrm{Sn}\left(\mathrm{NO}_{3}\right)_{2}$ or $0.1 \mathrm{M} \mathrm{Co}\left(\mathrm{NO}_{3}\right)_{2}$

## Acid-Base Properties of Salt Solutions

(Sample Problems 18.13 and 18.14)

## - Concept Review Questions

18.116 What determines whether an aqueous solution of a salt will be acidic, basic, or neutral? Give an example of each type of salt. 18.117 Why is aqueous NaF basic but aqueous NaCl neutral?
18.118 The $\mathrm{NH}_{4}{ }^{+}$ion forms acidic solutions, and the $\mathrm{CH}_{3} \mathrm{COO}^{-}$ion forms basic solutions. However, a solution of ammonium acetate is almost neutral. Do all of the ammonium salts of weak acids form neutral solutions? Explain your answer.

## Skill-Building Exercises (grouped in similar pairs)

18.119 Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a) KBr ; (b) $\mathrm{NH}_{4} \mathrm{I}$; (c) KCN .
18.120 Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a) $\mathrm{Cr}\left(\mathrm{NO}_{3}\right)_{3}$; (b) NaHS ; (c) $\mathrm{Zn}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2}$.
18.121 Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a) $\mathrm{Na}_{2} \mathrm{CO}_{3}$; (b) $\mathrm{CaCl}_{2}$; (c) $\mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}$.
18.122 Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a) $\mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{Cl}$; (b) $\mathrm{KClO}_{4}$; (c) $\mathrm{CoF}_{2}$.
18.123 Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a) $\mathrm{SrBr}_{2}$; (b) $\mathrm{Ba}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2}$; (c) $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}_{2} \mathrm{Br}$.
18.124 Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a) $\mathrm{Fe}\left(\mathrm{HCOO}_{3}\right.$; (b) $\mathrm{KHCO}_{3}$; (c) $\mathrm{K}_{2} \mathrm{~S}$.
18.125 Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a) $\left(\mathrm{NH}_{4}\right)_{3} \mathrm{PO}_{4}$; (b) $\mathrm{Na}_{2} \mathrm{SO}_{4}$; (c) LiClO .
18.126 Explain with equations and calculations, when necessary, whether an aqueous solution of each of these salts is acidic, basic, or neutral: (a) $\mathrm{Pb}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2}$; (b) $\mathrm{Cr}\left(\mathrm{NO}_{2}\right)_{3}$; (c) CsI.
18.127 Rank the following salts in order of increasing pH of their 0.1 M aqueous solutions:
(a) $\mathrm{KNO}_{3}, \mathrm{~K}_{2} \mathrm{SO}_{3}, \mathrm{~K}_{2} \mathrm{~S}, \mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{2}$
(b) $\mathrm{NH}_{4} \mathrm{NO}_{3}, \mathrm{NaHSO}_{4}, \mathrm{NaHCO}_{3}, \mathrm{Na}_{2} \mathrm{CO}_{3}$
18.128 Rank the following salts in order of decreasing pH of their 0.1 M aqueous solutions:
(a) $\mathrm{FeCl}_{2}, \mathrm{FeCl}_{3}, \mathrm{MgCl}_{2}, \mathrm{KClO}_{2}$
(b) $\mathrm{NH}_{4} \mathrm{Br}, \mathrm{NaBrO}_{2}, \mathrm{NaBr}, \mathrm{NaClO}_{2}$ AOagO PDE

## Generalizing the Brønsted-Lowry Concept: The Leveling Effect

## - Concept Review Questions

18.129 The methoxide ion, $\mathrm{CH}_{3} \mathrm{O}^{-}$, and amide ion, $\mathrm{NH}_{2}{ }^{-}$, are very strong bases that are "leveled" by water. What does this mean? Write the reactions that occur in the leveling process. What species do the two leveled solutions have in common?
18.130 Explain the differing extents of dissociation of $\mathrm{H}_{2} \mathrm{SO}_{4}$ in $\mathrm{CH}_{3} \mathrm{COOH}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{NH}_{3}$.
18.131 In $\mathrm{H}_{2} \mathrm{O}$, HF is weak and the other hydrohalic acids are equally strong. In $\mathrm{NH}_{3}$, however, all the hydrohalic acids are equally strong. Explain.

## Electron-Pair Donation and the Lewis Acid-Base Definition (Sample Problem 18.15)

## - Concept Review Questions

18.132 What feature must a molecule or ion have for it to act as a Lewis base? A Lewis acid? Explain the roles of these features.
18.133 How do Lewis acids differ from Brønsted-Lowry acids? How are they similar? Do Lewis bases differ from BrønstedLowry bases? Explain.
18.134 (a) Is a weak Brønsted-Lowry base necessarily a weak Lewis base? Explain with an example.
(b) Identify the Lewis bases in the following reaction:
$\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}(a q)+4 \mathrm{CN}^{-}(a q) \rightleftharpoons \mathrm{Cu}(\mathrm{CN})_{4}{ }^{2-}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)$ (c) Given that $K_{\mathrm{c}}>1$ for the reaction in part (b), which Lewis base is stronger?
18.135 In which of the three acid-base concepts can water be a product of an acid-base reaction? In which is it the only product? 18.136 (a) Give an example of a substance that is a base in two of the three acid-base definitions, but not in the third.
(b) Give an example of a substance that is an acid in one of the three acid-base definitions, but not in the other two.

## - Skill-Building Exercises (grouped in similar pairs)

18.137 Which are Lewis acids and which are Lewis bases?
(a) $\mathrm{Cu}^{2+}$
(b) $\mathrm{Cl}^{-}$
(c) $\mathrm{SnCl}_{2}$
(d) $\mathrm{OF}_{2}$
18.138 Which are Lewis acids and which are Lewis bases?
(a) $\mathrm{Na}^{+}$
(b) $\mathrm{NH}_{3}$
(c) $\mathrm{CN}^{-}$
(d) $\mathrm{BF}_{3}$
18.139 Which are Lewis acids and which are Lewis bases?
(a) $\mathrm{BF}_{3}$
(b) $\mathrm{S}^{2-}$
(c) $\mathrm{SO}_{3}{ }^{2-}$
(d) $\mathrm{SO}_{3}$
18.140 Which are Lewis acids and which are Lewis bases?
(a) $\mathrm{Mg}^{2+}$
(b) $\mathrm{OH}^{-}$
(c) $\mathrm{SiF}_{4}$
(d) $\mathrm{BeCl}_{2}$
18.141 Identify the Lewis acid and Lewis base in each equation:
(a) $\mathrm{Na}^{+}+6 \mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{Na}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{+}$
(b) $\mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{2} \mathrm{CO}_{3}$
(c) $\mathrm{F}^{-}+\mathrm{BF}_{3} \rightleftharpoons \mathrm{BF}_{4}^{-}$
18.142 Identify the Lewis acid and Lewis base in each equation:
(a) $\mathrm{Fe}^{3+}+2 \mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{FeOH}^{2+}+\mathrm{H}_{3} \mathrm{O}^{+}$
(b) $\mathrm{H}_{2} \mathrm{O}+\mathrm{H}^{-} \rightleftharpoons \mathrm{OH}^{-}+\mathrm{H}_{2}$
(c) $4 \mathrm{CO}+\mathrm{Ni} \rightleftharpoons \mathrm{Ni}(\mathrm{CO})_{4}$
18.143 Classify the following as Arrhenius, Brønsted-Lowry, or Lewis acid-base reactions. A reaction may fit all, two, one, or none of the categories:
(a) $\mathrm{Ag}^{+}+2 \mathrm{NH}_{3} \rightleftharpoons \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}$

F (b) $\mathrm{H}_{2} \mathrm{SO}_{4}+\mathrm{NH}_{3} \rightleftharpoons \mathrm{HSO}_{4}^{-}+\mathrm{NH}_{4}^{+}$
(c) $2 \mathrm{HCl} \rightleftharpoons \mathrm{H}_{2}+\mathrm{Cl}_{2}$
(d) $\mathrm{AlCl}_{3}+\mathrm{Cl}^{-} \rightleftharpoons \mathrm{AlCl}_{4}^{-}$
18.144 Classify the following as Arrhenius, Brønsted-Lowry, or Lewis acid-base reactions. A reaction may fit all, two, one, or none of the categories:
(a) $\mathrm{Cu}^{2+}+4 \mathrm{Cl}^{-} \rightleftharpoons \mathrm{CuCl}_{4}^{2-}$
(b) $\mathrm{Al}(\mathrm{OH})_{3}+3 \mathrm{HNO}_{3} \rightleftharpoons \mathrm{Al}^{3+}+3 \mathrm{H}_{2} \mathrm{O}+3 \mathrm{NO}_{3}{ }^{-}$
(c) $\mathrm{N}_{2}+3 \mathrm{H}_{2} \rightleftharpoons 2 \mathrm{NH}_{3}$
(d) $\mathrm{CN}^{-}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{HCN}+\mathrm{OH}^{-}$

## Comprehensive Problems

18.145 Pantothenic acid $\left(\mathrm{C}_{9} \mathrm{H}_{17} \mathrm{NO}_{5}\right.$; vitamin $\left.\mathrm{B}_{3}\right)$ is shown below. This biologically active molecule is an optical isomer that behaves like a monoprotic Brønsted-Lowry acid in water.

(a) Use the molecular formula to write the equation for the reaction of pantothenic acid with water and the $K_{\mathrm{a}}$ expression.
(b) Which C atom is the chiral center?
18.146 Chloral $\left(\mathrm{Cl}_{3} \mathrm{C}-\mathrm{CH}=\mathrm{O}\right)$ forms a monohydrate, chloral hydrate, the sleep-inducing depressant called "knockout drops" in old movies. (a) Write two possible structures for chloral hydrate, one involving hydrogen bonding and one that is a Lewis
adduct. (b) What spectroscopic method could be used to identify the real structure? Explain.
18.147 In humans, blood pH is maintained within a narrow range: acidosis occurs if the blood pH is below 7.35, and alkalosis occurs if the pH is above 7.45 . Given that the $\mathrm{p} K_{\mathrm{w}}$ of blood is 13.63 at $37^{\circ} \mathrm{C}$ (body temperature), what is the normal range of $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$ and of $\left[\mathrm{OH}^{-}\right]$in blood?
18.148 The disinfectant phenol, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}$, has a $\mathrm{p} K_{\mathrm{a}}$ of 10.0 in water, but 14.4 in methanol. (a) Why are the values different? (b) Is methanol is a stronger or weaker base than water? (c) Write the dissociation reaction of phenol in methanol. (d) Write an expression for the autoionization constant of methanol.
18.149 When carbon dioxide dissolves in water, it undergoes a multistep equilibrium process, with $K_{\text {overall }}=4.5 \times 10^{-7}$, which is simplified to the following:

$$
\begin{aligned}
\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \rightleftharpoons \mathrm{H}_{2} \mathrm{CO}_{3}(a q) \\
\mathrm{H}_{2} \mathrm{CO}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) & \rightleftharpoons \mathrm{HCO}_{3}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)
\end{aligned}
$$

(a) Classify each step as a Lewis or a Brønsted-Lowry reaction.
(b) What is the pH of nonpolluted rainwater in equilibrium with clean air $\left(P_{\mathrm{CO}_{2}}\right.$ in clean air $=3.2 \times 10^{-4} \mathrm{~atm}$; Henry's law constant for $\mathrm{CO}_{2}$ at $25^{\circ} \mathrm{C}$ is $\left.0.033 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm}\right)$ ?
(c) What is $\left[\mathrm{CO}_{3}{ }^{2-}\right]$ in rainwater $\left(K_{\mathrm{a}}\right.$ of $\left.\mathrm{HCO}_{3}{ }^{-}=4.7 \times 10^{-11}\right)$ ?
(d) If the partial pressure of $\mathrm{CO}_{2}$ in clean air doubles in the next few decades, what will the pH of rainwater become?
18.150 Seashells are mostly calcium carbonate, which reacts with $\mathrm{H}_{3} \mathrm{O}^{+}$according to the equation
$\mathrm{CaCO}_{3}(s)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \rightleftharpoons \mathrm{Ca}^{2+}(a q)+\mathrm{HCO}_{3}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$
If $K_{\mathrm{w}}$ increases at higher pressure, will seashells dissolve more rapidly near the surface of the ocean or at great depths? Explain. 18.151 Many molecules with central atoms fromPeried erhigherDE take part in Lewis acid-base reactions in whichthe central atom expands its valence shell. $\mathrm{SnCl}_{4}$ reacts with $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{~N}$ as follows:

(a) Identify the Lewis acid and the Lewis base in the reaction.
(b) Give the $n l$ designation of the sublevel of the central atom in the acid before it accepts the lone pair.
18.152 A chemist makes four successive 1:10 dilutions of $1.0 \times 10^{-5} M \mathrm{HCl}$. Calculate the pH of the original solution and of each diluted solution (through $1.0 \times 10^{-9} \mathrm{M} \mathrm{HCl}$ ).
18.153 Chlorobenzene, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$, is a key intermediate in the manufacture of dyes and pesticides. It is made by the chlorination of benzene, catalyzed by $\mathrm{FeCl}_{3}$, in this series of steps:
(1) $\mathrm{Cl}_{2}+\mathrm{FeCl}_{3} \rightleftharpoons \mathrm{FeCl}_{5}$ ( or $\mathrm{Cl}^{+} \mathrm{FeCl}_{4}^{-}$)
(2) $\mathrm{C}_{6} \mathrm{H}_{6}+\mathrm{Cl}^{+} \mathrm{FeCl}_{4}^{-} \rightleftharpoons \mathrm{C}_{6} \mathrm{H}_{6} \mathrm{Cl}^{+}+\mathrm{FeCl}_{4}^{-}$
(3) $\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{Cl}^{+} \rightleftharpoons \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}+\mathrm{H}^{+}$
(4) $\mathrm{H}^{+}+\mathrm{FeCl}_{4}^{-} \rightleftharpoons \mathrm{HCl}+\mathrm{FeCl}_{3}$
(a) Which of the step(s) is (are) Lewis acid-base reactions?
(b) Identify the Lewis acids and bases in each of those steps.
18.154 The beakers shown contain 0.300 L of aqueous solutions of a moderately weak acid HY. Each particle represents 0.010 mol ; solvent molecules are omitted for clarity. (a) The reaction in
beaker A is at equilibrium. Calculate $Q$ for $\mathrm{B}, \mathrm{C}$, and D to determine which, if any, is also at equilibrium. (b) For any not at equilibrium, in which direction does the reaction proceed? (c) Does dilution affect the extent of dissociation of a weak acid? Explain.

18.155 Hydrogen peroxide, $\mathrm{H}_{2} \mathrm{O}_{2}\left(\mathrm{p} K_{\mathrm{a}}=11.75\right)$, is a bleaching agent and antiseptic. It is sold as $3 \% \mathrm{H}_{2} \mathrm{O}_{2}$ by mass and contains $0.001 \% \mathrm{H}_{3} \mathrm{PO}_{4}$ by mass to stabilize the solution. Which contributes more $\mathrm{H}_{3} \mathrm{O}^{+}$to the solution, the $\mathrm{H}_{2} \mathrm{O}_{2}$ or the $\mathrm{H}_{3} \mathrm{PO}_{4}$ ?
18.156 The strength of an acid or base is related to its strength as an electrolyte. (a) Is the electrical conductivity of 0.1 M HCl higher, lower, or the same as that of $0.1 \mathrm{M} \mathrm{CH}_{3} \mathrm{COOH}$ ? Explain. (b) Is the electrical conductivity of $1 \times 10^{-7} \mathrm{M} \mathrm{HCl}$ higher, lower, or the same as that of $1 \times 10^{-7} M \mathrm{CH}_{3} \mathrm{COOH}$ ? Explain.
18.157 Esters, $\mathrm{RCOOR}^{\prime}$, are formed by the reaction of carboxylic acids, RCOOH , and alcohols, $\mathrm{R}^{\prime} \mathrm{OH}$, where R and $\mathrm{R}^{\prime}$ are hydrocarbon groups. Many esters are responsible for the odors of fruit and, thus, have important uses in the food and cosmetics industries. The first two steps in the mechanism of ester formation are

Identify the Lewis acids and Lewis bases in these two steps.
18.158 Three beakers contain $100 . \mathrm{mL}$ of 0.10 M acid, either HCl , $\mathrm{HClO}_{2}$, or HClO . (a) Find the pH of each. (b) Describe quantitatively how to make the pH equal in the beakers through the addition of water only.
18.159 Human urine has a normal pH of 6.2. If a person eliminates an average of $1250 . \mathrm{mL}$ of urine per day, how many $\mathrm{H}^{+}$ions are eliminated per week?
18.160 Liquid ammonia autoionizes like water:

$$
2 \mathrm{NH}_{3}(l) \longrightarrow \mathrm{NH}_{4}^{+}(a m)+\mathrm{NH}_{2}^{-}(a m)
$$

where $(\mathrm{am})$ represents solvation by $\mathrm{NH}_{3}$.
(a) Write the ion-product constant expression, $K_{\mathrm{am}}$.
(b) What are the strongest acid and base that can exist in $\mathrm{NH}_{3}(l)$ ?
(c) $\mathrm{HNO}_{3}$ and HCOOH are leveled in $\mathrm{NH}_{3}(l)$. Explain with equations.
(d) At the boiling point $\left(-33^{\circ} \mathrm{C}\right), K_{\mathrm{am}}=5.1 \times 10^{-27}$. Calculate $\left[\mathrm{NH}_{4}{ }^{+}\right]$at this temperature.
(e) Pure sulfuric acid also autoionizes. Write the ion-product constant expression, $K_{\text {sulf }}$, and find the concentration of the conjugate base at $20^{\circ} \mathrm{C}\left(K_{\text {sulf }}=2.7 \times 10^{-4}\right.$ at $\left.20^{\circ} \mathrm{C}\right)$.
18.161 Autoionization (see Problem 18.160) occurs in methanol $\left(\mathrm{CH}_{3} \mathrm{OH}\right)$ and in ethylenediamine $\left(\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\right)$.
(a) The autoionization constant of methanol $\left(K_{\text {met }}\right)$ is $2 \times 10^{-17}$. What is $\left[\mathrm{CH}_{3} \mathrm{O}^{-}\right.$] in pure $\mathrm{CH}_{3} \mathrm{OH}$ ?
(b) The concentration of $\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{3}{ }^{+}$in pure $\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}$ is $2 \times 10^{-8} \mathrm{M}$. What is the autoionization constant of ethylenediamine ( $K_{\text {en }}$ )?
18.162 Thiamine hydrochloride $\left(\mathrm{C}_{12} \mathrm{H}_{18} \mathrm{ON}_{4} \mathrm{SCl}_{2}\right)$ is a watersoluble form of thiamine (vitamin $\mathrm{B}_{1} ; K_{\mathrm{a}}=3.37 \times 10^{-7}$ ). How many grams of the hydrochloride must be dissolved in 10.00 mL of water to give a pH of 3.50 ?
18.163 Tris(hydroxymethyl)aminomethane, known as TRIS or THAM, is a water-soluble base used to synthesize surfactants and pharmaceuticals, as an emulsifying agent in cosmetics, and in cleaning mixtures for textiles and leather. In biomedical research, solutions of TRIS are used to maintain nearly constant pH for the study of enzymes and other cellular components. Given that the $\mathrm{p} K_{\mathrm{b}}$ is 5.91 , calculate the pH of $0.075 M$ TRIS.
18.164 When $\mathrm{Fe}^{3+}$ salts are dissolved in water, the solution becomes acidic due to formation of $\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{OH}^{2+}$ and $\mathrm{H}_{3} \mathrm{O}^{+}$. The overall process involves both Lewis and Brønsted-Lowry acid-base reactions. Write the equations for the process.
18.165 What is the pH of a vinegar with $5.0 \%(\mathrm{w} / \mathrm{v})$ acetic acid in water?
18.166 How would you differentiate between a strong and a weak monoprotic acid from the results of the following procedures?
(a) Electrical conductivity of an equimolar solution of each acid is measured. (b) Equal molarities of each are tested with pH paper. (c) Zinc metal is added to solutions of equal concentration.
18.167 At $50^{\circ} \mathrm{C}$ and $1 \mathrm{~atm}, K_{\mathrm{w}}=5.19 \times 10^{-14}$. At these conditions, find (a) $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$in pure water, (b) $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$in 0.010 M NaOH , and (c) $\left[\mathrm{OH}^{-}\right]$in $0.0010 M \mathrm{HClO}_{4}$. (d) Find $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$in 0.0100 M KOH at $100^{\circ} \mathrm{C}$ and $1000 \mathrm{~atm}\left(K_{\mathrm{w}}=1.10 \times 10^{-12}\right)$. (e) Find the pH of pure water at $100^{\circ} \mathrm{C}$ and 1000 atm.O OO PDE
18.168 The catalytic efficiency of an enzyme is called its activity and refers to the rate at which it catalyzes the reaction. Most enzymes have optimum activity over a relatively narrow pH range, which is related to the pH of the local cellular fluid. The pH profiles of three digestive enzymes are shown.

Salivary amylase begins digestion of starches in the mouth and has optimum activity at a pH of 6.8 ; pepsin begins protein digestion in the stomach and has optimum activity at a pH of 2.0 ; and trypsin, released in pancreatic juices, continues protein digestion in the small intestine and has optimum activity at a pH of 9.5. Calculate $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$in the local cellular fluid for each enzyme.
18.169 Acetic acid has a $K_{\mathrm{a}}$ of $1.8 \times 10^{-5}$, and ammonia has a $K_{\mathrm{b}}$ of $1.8 \times 10^{-5}$. Find $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right],\left[\mathrm{OH}^{-}\right], \mathrm{pH}$, and pOH for (a) 0.240 M acetic acid and (b) 0.240 M ammonia.
18.170 The uses of sodium phosphate include clarifying crude sugar, manufacturing paper, removing boiler scale, and washing concrete. What is the pH of a solution containing 33 g of $\mathrm{Na}_{3} \mathrm{PO}_{4}$ per liter? What is $\left[\mathrm{OH}^{-}\right]$of this solution?
18.171 The Group $5 \mathrm{~A}(15)$ hydrides react with boron trihalides in a reversible Lewis acid-base reaction. When 0.15 mol of
$\mathrm{PH}_{3} \mathrm{BCl}_{3}(s)$ is introduced into a 3.0-L container at a certain temperature, $8.4 \times 10^{-3} \mathrm{~mol}$ of $\mathrm{PH}_{3}$ is present at equilibrium: $\mathrm{PH}_{3} \mathrm{BCl}_{3}(s) \rightleftharpoons \mathrm{PH}_{3}(g)+\mathrm{BCl}_{3}(g)$. (a) Find $K_{\mathrm{c}}$ for the reaction at this temperature. (b) Draw a Lewis structure for the reactant.
18.172 A 1.000 m solution of chloroacetic acid $\left(\mathrm{ClCH}_{2} \mathrm{COOH}\right)$ freezes at $-1.93^{\circ} \mathrm{C}$. Find the $K_{\mathrm{a}}$ of chloroacetic acid. (Assume the molarities equal the molalities.)
18.173 Sodium stearate $\left(\mathrm{C}_{17} \mathrm{H}_{35} \mathrm{COONa}\right)$ is a major component of bar soap. The $K_{\mathrm{a}}$ of the stearic acid is $1.3 \times 10^{-5}$. What is the pH of 10.0 mL of a solution containing 0.42 g of sodium stearate?
18.174 Calcium propionate $\left[\mathrm{Ca}\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{COO}\right)_{2}\right.$; calcium propanoate] is a mold inhibitor used in food, tobacco, and pharmaceuticals. (a) Use balanced equations to show whether aqueous calcium propionate is acidic, basic, or neutral. (b) Use Appendix C to find the resulting pH when 8.75 g of $\mathrm{Ca}\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{COO}\right)_{2}$ dissolves in enough water to give 0.500 L of solution.
18.175 A site in Pennsylvania receives a total annual deposition of $2.688 \mathrm{~g} / \mathrm{m}^{2}$ of sulfate from fertilizer and acid rain. The ratio by mass of ammonium sulfate/ammonium bisulfate/sulfuric acid is 3.0/5.5/1.0. (a) How much acid, expressed as kg of sulfuric acid, is deposited over an area of $10 . \mathrm{km}^{2}$ ? (b) How many pounds of $\mathrm{CaCO}_{3}$ are needed to neutralize this acid? (c) If $10 . \mathrm{km}^{2}$ is the area of an unpolluted lake 3 m deep and there is no loss of acid, what pH would be attained in the year? (Assume constant volume.) 18.176 (a) If $K_{\mathrm{w}}=1.139 \times 10^{-15}$ at $0^{\circ} \mathrm{C}$ and $5.474 \times 10^{-14}$ at $50^{\circ} \mathrm{C}$, find $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and pH of water at $0^{\circ} \mathrm{C}$ and $50^{\circ} \mathrm{C}$.
(b) The autoionization constant for heavy water (deuterium oxide, $\mathrm{D}_{2} \mathrm{O}$ ) is $3.64 \times 10^{-16}$ at $0^{\circ} \mathrm{C}$ and $7.89 \times 10^{-15}$ at $50^{\circ} \mathrm{C}$. Find $\left[\mathrm{D}_{3} \mathrm{O}^{+}\right]$and pD of heavy water at $0^{\circ} \mathrm{C}$ and $50^{\circ} \mathrm{C}$.
Fif Sugestaneason for these differences.
$18.177 \mathrm{HX}(\mathcal{M}=150 \mathrm{~g} / \mathrm{mol})$ and $\mathrm{HY}(\mathcal{M}=50.0 \mathrm{~g} / \mathrm{mol})$ are weak acids. A solution of $12.0 \mathrm{~g} / \mathrm{L}$ of HX has the same pH as one containing $6.00 \mathrm{~g} / \mathrm{L}$ of HY. Which is the stronger acid? Why?
18.178 The beakers below depict the aqueous dissociations of weak acids HA (blue and green) and HB (blue and yellow); solvent molecules are omitted for clarity. If the HA solution is 0.50 L , and the HB solution is 0.25 L , and each particle represents 0.010 mol, find the $K_{\mathrm{a}}$ of each acid. Which acid, if either, is stronger?

18.179 In his acid-base studies, Arrhenius discovered an important fact involving reactions like the following:

$$
\begin{aligned}
\mathrm{KOH}(a q)+\mathrm{HNO}_{3}(a q) & \longrightarrow ? \\
\mathrm{NaOH}(a q)+\mathrm{HCl}(a q) & \longrightarrow ?
\end{aligned}
$$

(a) Complete the reactions and use the data for the individual ions in Appendix B to calculate each $\Delta H_{\mathrm{rxn}}^{\circ}$.
(b) Explain your results and use them to predict $\Delta H_{\mathrm{rxn}}^{\circ}$ for

$$
\mathrm{KOH}(a q)+\mathrm{HCl}(a q) \longrightarrow \text { ? }
$$

18.180 Putrescine $\left[\mathrm{NH}_{2}\left(\mathrm{CH}_{2}\right)_{4} \mathrm{NH}_{2}\right]$, found in rotting animal tissue, is now known to be in all cells and essential for normal and abnormal (cancerous) growth. It also plays a key role in the formation of GABA, a neurotransmitter. A 0.10 M aqueous solution of putrescine has $\left[\mathrm{OH}^{-}\right]=2.1 \times 10^{-3}$. What is the $K_{\mathrm{b}}$ ?
18.181 The molecular scene depicts the relative concentrations of $\mathrm{H}_{3} \mathrm{O}^{+}$(purple) and $\mathrm{OH}^{-}$(green) in an aqueous solution at $25^{\circ} \mathrm{C}$. (Counter ions and solvent molecules are omitted for clarity.) (a) Calculate the pH. (b) How many $\mathrm{H}_{3} \mathrm{O}^{+}$ions would you have to draw for every $\mathrm{OH}^{-}$ion to depict a solution of pH 4 ?

18.182 Polymers are not very soluble in water, but their solubility increases if they have charged groups. (a) Casein, a milk protein, contains many - $\mathrm{COO}^{-}$groups on its side chains. How does the solubility of casein vary with pH ? (b) Histones are proteins essential to the function of DNA. They are weakly basic due to the presence of side chains with $-\mathrm{NH}_{2}$ and $=\mathrm{NH}$ groups. How does the solubility of a histone vary with pH ?
18.183 Hemoglobin $(\mathrm{Hb})$ transports oxygen in the blood:
$\mathrm{HbH}^{+}(a q)+\mathrm{O}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{HbO}_{2}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)$ In blood, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$is held nearly constant at $4 \times 10^{-8} \mathrm{M}$.
(a) How does the equilibrium position change in the lungs?
(b) How does it change in $\mathrm{O}_{2}$-deficient cells?
(c) Excessive vomiting may lead to metabolic alkalosis, in which $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$in blood decreases. How does this condition affect the ability of Hb to transport $\mathrm{O}_{2}$ ?
(d) Diabetes mellitus may lead to metabolic acidosis, in which $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$in blood increases. How does this condition affect the ability of Hb to transport $\mathrm{O}_{2}$ ?
18.184 Nitrogen is discharged from wastewater treatment facilities into rivers and streams, usually as $\mathrm{NH}_{3}$ and $\mathrm{NH}_{4}{ }^{+}$:
$\mathrm{NH}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q) \quad K_{\mathrm{b}}=1.76 \times 10^{-5}$ One strategy for removing it is to raise the pHaff crfip" the $\mathrm{NH}_{3}$ from solution by bubbling air through the water. (a) At pH 7.00 , what fraction of the total nitrogen in solution is $\mathrm{NH}_{3}$, defined as $\left[\mathrm{NH}_{3}\right] /\left(\left[\mathrm{NH}_{3}\right]+\left[\mathrm{NH}_{4}{ }^{+}\right]\right)$? (b) What is the fraction at pH 10.00? (c) Explain the basis of ammonia stripping.
18.185 Kevlar®, a polymeric aromatic amide, is synthesized from the monomers $p$-phenylenediamine (left) and terephthaloyl chloride (right). The polymer strands are initially aligned randomly, but they are dissolved and spun to give a lightweight, flexible product that is five times stronger than steel of the same weight.

The first step in the reaction of an amine with an acid chloride is

(a) Describe this step in terms of a Lewis acid-base reaction.
(b) Would you expect water or ammonia to react faster with an acid chloride? Explain.
18.186 A solution of propanoic acid $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{COOH}\right)$, made by dissolving 7.500 g in sufficient water to make 100.0 mL , has a freezing point of $-1.890^{\circ} \mathrm{C}$.
(a) Calculate the molarity of the solution.
(b) Calculate the molarity of the propanoate ion. (Assume the molarity of the solution equals the molality.)
(c) Calculate the percent dissociation of propanoic acid.
18.187 The antimalarial properties of quinine $\left(\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{~N}_{2} \mathrm{O}_{2}\right)$ saved thousands of lives during construction of the Panama Canal. This substance is a classic example of the medicinal wealth of tropical forests. Both N atoms are basic, but the N (colored) of the $3^{\circ}$ amine group is far more ba$\operatorname{sic}\left(\mathrm{p} K_{\mathrm{b}}=5.1\right)$ than the N within the
 aromatic ring system ( $\mathrm{p} K_{\mathrm{b}}=9.7$ ).
(a) A saturated solution of quinine in water is only $1.6 \times 10^{-3} M$. What is the pH of this solution?
(b) Show that the aromatic N contributes negligibly to the pH of the solution.
(c) Because of its low solubility, quinine is given as the salt quinine hydrochloride $\left(\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{~N}_{2} \mathrm{O}_{2} \cdot \mathrm{HCl}\right)$, which is 120 times more soluble than quinine. What is the pH of 0.33 M quinine hydrochloride?
(d) An antimalarial concentration in water is $1.5 \%$ quinine hy-

18.188 Drinking water is often disinfected with $\mathrm{Cl}_{2}$, which hydrolyzes to form HClO , a weak acid but powerful disinfectant: $\mathrm{Cl}_{2}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{HClO}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{Cl}^{-}(a q)$ The fraction of HClO in solution is defined as

$$
\frac{[\mathrm{HClO}]}{[\mathrm{HClO}]+\left[\mathrm{ClO}^{-}\right]}
$$

(a) What is the fraction of HClO at $\mathrm{pH} 7.00\left(K_{\mathrm{a}}\right.$ of $\mathrm{HClO}=$ $2.9 \times 10^{-8}$ )? (b) What is the fraction at pH 10.00 ?
18.189 The following scenes represent three weak acids HA (where $\mathrm{A}=\mathrm{X}, \mathrm{Y}$, or Z$)$ dissolved in water $\left(\mathrm{H}_{2} \mathrm{O}\right.$ is not shown):

(a) Rank the acids in order of increasing $K_{\mathrm{a}}$. (b) Rank the acids in order of increasing $\mathrm{p} K_{\mathrm{a}}$. (c) Rank the conjugate bases in order of increasing $\mathrm{p} K_{\mathrm{b}}$. (d) What is the percent dissociation of HX?
(e) If equimolar amounts of the sodium salts of the acids ( NaX , NaY , and NaZ ) were dissolved in water, which solution would have the highest pOH ? The lowest pH ?

Magnificent Shifts in Balance Awesome, subterranean limestone formations, such as these in the caves of Nerja on Spain's Costa del Sol, result from gradual shifts in the equilibrium positions of carbonate systems over eons. In this chapter, we explore the quantitative basis of three major types of aqueous ionic equilibriathose involving acid-base buffers, slightly soluble salts, and complex ions.

## Ionic Equilibria in Aqueous Systems

19.1 Equilibria of Acid-Base Buffer Systems
The Common-Ion Effect
The Henderson-Hasselbalch Equation
Buffer Capacity and Range
Preparing a Buffer
19.2 Acid-Base Titration Curves

Acid-Base Indicators
Strong Acid-Strong Base Titrations
Weak Acid-Strong Base Titrations
Weak Base-Strong Acid Titrations
Polyprotic Acid Titrations
Amino Acids as Polyprotic Acids

### 19.3 Equilibria of Slightly Soluble Ionic Compounds

The Solubility-Product Constant ( $K_{\text {sp }}$ )
Calculations Involving $K_{\text {sp }}$
The Effect of a Common Ion
The Effect of pH
$Q_{\text {sp }}$ vs. $K_{\text {sp }}$
Selective Precipitation of Ions

### 19.4 Equilibria Involving Complex Ions

Formation of Complex Ions
Complex Ions and Solubility
Amphoteric Hydroxides

## Concepts \& Skills to Review before you study this chapter

- solubility rules for ionic compounds (Section 4.3)
- effect of concentration on equilibrium position (Section 17.6)
- conjugate acid-base pairs (Section 18.3)
- calculations for weak-acid and weak-base equilibria
(Sections 18.4 and 18.5)
- acid-base properties of salt solutions (Section 18.7)
- Lewis acids and bases
(Section 18.9)

Figure 19.1 The effect of adding acid or base to an unbuffered solution.
A, A $100-\mathrm{mL}$ sample of dilute HCl is adjusted to pH 5.00 . B, After the addition of 1 mL of 1 M HCl (left) or of 1 M NaOH (right), the pH changes by several units.

Europa, one of Jupiter's moons, has an icy surface with hints of vast oceans of liquid water beneath. Is there life on Europa? If so, perhaps some Europan astronomer viewing Earth would be asking the same question, because liquid water is essential for the aqueous systems that maintain life. Every astronaut has felt awe at seeing our "beautiful blue orb" from space. A biologist peering at the fabulous watery world of a living cell probably feels the same way. A chemist is awed by the principles of equilibrium and their universal application to aqueous solutions wherever they occur.

Consider just a few cases of aqueous equilibria. The magnificent formations in limestone caves and the vast expanses of oceanic coral reefs result from subtle shifts in carbonate solubility equilibria. Carbonates also influence soil pH and prevent acidification of lakes by acid rain. Equilibria involving carbon dioxide and phosphates help organisms maintain cellular pH within narrow limits. Equilibria involving clays in soils control the availability of ionic nutrients for plants. The principles of ionic equilibrium also govern how water is softened, how substances are purified by precipitation of unwanted ions, and even how the weak acids in wine and vinegar influence the delicate taste of a fine French sauce.

IN THIS CHAPTER . . . We explore three aqueous ionic equilibrium systems: acid-base buffers, slightly soluble salts, and complex ions. Our discussion of buffers introduces the common-ion effect, an important phenomenon in many ionic equilibria. We discuss why buffers are important, how they work, and how to prepare them, and we then examine the various types of acid-base titrations and how buffered solutions are involved in them. Slightly soluble salts have major roles in the laboratory and in nature, and we'll see how conditions influence their solubility equilibria. Finally, we investigate how complex ions form and change from one type to another.

### 19.1 EQUILIBRIA OF ACID-BASE BUFFER SYSTEMS

Why do some lakes become acidic when showered by acid rain, while others remain unaffected? How does blood maintain a constant pH in contact with countless cellular acid-base reactions? How can a chemist sustain a nearly constant $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right.$] in reactions that consume or produce $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$? The answer in each case depends on the action of a buffer. In everyday language, a buffer is something that lessens the impact of an external force. An acid-base buffer is a solution that lessens the impact on pH from the addition of acid or base. Figure 19.1 shows that a small amount of $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$added to an unbuffered solution (or just water) changes the pH by several units. Note that, because of the logarithmic nature of pH , this change is several orders of magnitude larger than the change that results from the same addition to a buffered solution, shown in Figure 19.2. To withstand the addition of strong acid or strong base without signifi-

cantly changing its pH , a buffer must contain an acidic component that can react with the added $\mathrm{OH}^{-}$ion and a basic component that can react with added $\mathrm{H}_{3} \mathrm{O}^{+}$ ion. However, these buffer components cannot be just any acid and base because they would neutralize each other. Most often, the components of a buffer are the conjugate acid-base pair of a weak acid (or base). The buffer in Figure 19.2, for example, is a mixture of acetic acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$ and acetate ion $\left(\mathrm{CH}_{3} \mathrm{COO}^{-}\right)$.

## How a Buffer Works: The Common-Ion Effect

Buffers work through a phenomenon known as the common-ion effect. An example of this effect occurs when acetic acid dissociates in water and some sodium acetate is added. As you know, acetic acid dissociates only slightly in water:

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)
$$

From Le Châtelier's principle (Section 17.6), we know that if some $\mathrm{CH}_{3} \mathrm{COO}^{-}$ion is added (from the soluble sodium acetate), the equitibrium position shifts to the left; thus, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$decreases, in effect-Howering the extent of acid dissociation:-

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q ; \text { added })
$$

Similarly, if we dissolve acetic acid in a sodium acetate solution, acetate ion and $\mathrm{H}_{3} \mathrm{O}^{+}$ion from the acid enter the solution. The acetate ion already present in the solution acts to suppress the acid from dissociating as much as it would in pure water, thus keeping the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$lower. The effect again is to lower the acid dissociation. Acetate ion is called the common ion in this case because it is "common" to both the acetic acid and sodium acetate solutions; that is, acetate ion from the acid enters a solution in which it is already present. The common-ion effect occurs when a given ion is added to an equilibrium mixture that already contains that ion, and the position of equilibrium shifts away from forming more of it.

Table 19.1 shows the percent dissociation and the pH of an acetic acid solution containing various concentrations of acetate ion (supplied from solid sodium acetate). Note that the common ion, $\mathrm{CH}_{3} \mathrm{COO}^{-}$, suppresses the dissociation of $\mathrm{CH}_{3} \mathrm{COOH}$, which makes the solution less acidic (higher pH ).

| $\left[\mathrm{CH}_{3} \mathrm{COOH}\right]_{\text {init }}$ | $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]_{\text {added }}$ | \% Dissociation* | pH |
| :---: | :---: | :---: | :---: |
| 0.10 | 0.00 | 1.3 | 2.89 |
| 0.10 | 0.050 | 0.036 | 4.44 |
| 0.10 | 0.10 | 0.018 | 4.74 |
| 0.10 | 0.15 | 0.012 | 4.92 |

$* \%$ Dissociation $=\frac{\left[\mathrm{CH}_{3} \mathrm{COOH}\right]_{\text {dissoc }}}{\left[\mathrm{CH}_{3} \mathrm{COOH}\right]_{\text {init }}} \times 100$

Figure 19.2 The effect of adding acid or base to a buffered solution.
A, A $100-\mathrm{mL}$ sample of a buffered solution, made by mixing $1 \mathrm{MCH} \mathrm{COOH}_{3}$ with $1 \mathrm{M} \mathrm{CH}_{3} \mathrm{COONa}$, is adjusted to pH 5.00 . B, After the addition of 1 mL of 1 M HCl (left) or of 1 M NaOH (right), the pH change is negligibly small. Compare these changes with those in Figure 19.1.

The Essential Feature of a Buffer In the previous case, we prepared a buffer by mixing a weak acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$ and its conjugate base $\left(\mathrm{CH}_{3} \mathrm{COO}^{-}\right)$. How does this solution resist pH changes when $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$is added? The essential feature of a buffer is that it consists of high concentrations of the acidic (HA) and basic ( $A^{-}$) components. When small amounts of $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$ions are added to the buffer, they cause a small amount of one buffer component to convert into the other, which changes the relative concentrations of the two components. As long as the amount of $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$added is much smaller than the amounts of HA and $\mathrm{A}^{-}$present originally, the added ions have little effect on the pH because they are consumed by one or the other buffer component: a large excess of $\mathrm{A}^{-}$reacts with any added $\mathrm{H}_{3} \mathrm{O}^{+}$, and a large excess of HA reacts with any added $\mathrm{OH}^{-}$.

Consider what happens quantitatively to a solution containing high $\left[\mathrm{CH}_{3} \mathrm{COOH}\right]$ and high $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]$when we add small amounts of strong acid or base. The expression for HA dissociation at equilibrium is

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}{\left[\mathrm{CH}_{3} \mathrm{COOH}\right]}
$$

Solving for $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$gives

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=K_{\mathrm{a}} \times \frac{\left[\mathrm{CH}_{3} \mathrm{COOH}\right]}{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]}
$$

Note that because $K_{\mathrm{a}}$ is constant, the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$of the solution depends directly on the buffer-component concentration ratio, $\frac{\left[\mathrm{CH}_{3} \mathrm{COOH}\right]}{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]}$:

- If the ratio $[\mathrm{HA}] /\left[\mathrm{A}^{-}\right]$goes up, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$goes up.
- If the ratio $[\mathrm{HA}] /\left[\mathrm{A}^{-}\right]$goes down, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$goes down.
 ion reacts with a stoichiometric amount of acetate ion from the buffer to form more acetic acid:

$$
\mathrm{H}_{3} \mathrm{O}^{+}(a q ; \text { added })+\mathrm{CH}_{3} \mathrm{COO}^{-}(a q ; \text { from buffer }) \longrightarrow \mathrm{CH}_{3} \mathrm{COOH}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

As a result, $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]$goes down by that amount and $\left[\mathrm{CH}_{3} \mathrm{COOH}\right]$ goes up by that amount, which increases the buffer-component concentration ratio (Figure 19.3, left). The $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$also increases but only very slightly.

Figure 19.3 How a buffer works.
A buffer consists of high concentrations of a conjugate acid-base pair, in this case, acetic acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$ and acetate ion $\left(\mathrm{CH}_{3} \mathrm{COO}^{-}\right)$. When a small amount of $\mathrm{H}_{3} \mathrm{O}^{+}$is added (left), that same amount of $\mathrm{CH}_{3} \mathrm{COO}^{-}$combines with it, which increases the amount of $\mathrm{CH}_{3} \mathrm{COOH}$ slightly. Similarly, when a small amount of $\mathrm{OH}^{-}$is added (right), that amount of $\mathrm{CH}_{3} \mathrm{COOH}$ combines with it, which increases the amount of $\mathrm{CH}_{3} \mathrm{COO}^{-}$ slightly. In both cases, the relative changes in amounts of the buffer components are small, so the changes in their concentration ratio, and therefore the pH , are small as well.

Buffer after addition of $\mathrm{H}_{3} \mathrm{O}^{+}$

Buffer with equal concentrations of conjugate base and acid

Adding a small amount of strong base produces the opposite result. It supplies $\mathrm{OH}^{-}$ions, which react with a stoichiometric amount of $\mathrm{CH}_{3} \mathrm{COOH}$ from the buffer, forming that much more $\mathrm{CH}_{3} \mathrm{COO}^{-}$(Figure 19.3, right):

$$
\mathrm{CH}_{3} \mathrm{COOH}(a q \text {; from buffer })+\mathrm{OH}^{-}(a q ; \text { added }) \longrightarrow \mathrm{CH}_{3} \mathrm{COO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

The buffer-component concentration ratio decreases, which decreases $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$, but once again, the change is very slight.

Thus, the buffer components consume virtually all the added $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$. To reiterate, as long as the amount of added $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$is small compared with the amounts of the buffer components, the conversion of one component into the other produces a small change in the buffer-component concentration ratio and, consequently, a small change in $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and in pH . Sample Problem 19.1 demonstrates how small these pH changes typically are. Note that the latter two parts of the problem combine a stoichiometry portion, like the problems in Chapter 3, and a weak-acid dissociation portion, like those in Chapter 18.

SAMPLE PROBLEM 19.1 Calculating the Effect of Added $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$ on Buffer pH
PROBLEM Calculate the pH :
(a) Of a buffer solution consisting of $0.50 \mathrm{M} \mathrm{CH}_{3} \mathrm{COOH}$ and $0.50 \mathrm{M} \mathrm{CH} \mathrm{H}_{3} \mathrm{COONa}$
(b) After adding 0.020 mol of solid NaOH to 1.0 L of the buffer solution in part (a)
(c) After adding 0.020 mol of HCl to 1.0 L of the buffer solution in part (a)
$K_{\mathrm{a}}$ of $\mathrm{CH}_{3} \mathrm{COOH}=1.8 \times 10^{-5}$. (Assume the additions cause negligible volume changes.) PLAN In each case, we know, or can find, $\left[\mathrm{CH}_{3} \mathrm{COOH}\right]_{\text {init }}$ and $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]_{\text {init }}$ and the $K_{\mathrm{a}}$ of $\mathrm{CH}_{3} \mathrm{COOH}\left(1.8 \times 10^{-5}\right)$, and we need to find $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$at equilibrium and convert it to pH . (a) We use the given concentrations of buffer components (each 0.50 M ) as the initial values. As in earlier problems, we assume that $x$, the $\left[\mathrm{CH}_{3} \mathrm{COOH}\right]$ that dissociates, which equals $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$, is so small relative to $\left[\mathrm{CH}_{3} \mathrm{COOH}\right]_{\text {init }}$ that it can be neglected. We set up a reaction table, solve for $x$, and check the assumption. (b) and (c) We assume that the added $\mathrm{OH}^{-}$or $\mathrm{H}_{3} \mathrm{O}^{+}$reacts completely with the buffer components to yield new $\left[\mathrm{CH}_{3} \mathrm{COOH}\right]_{\text {init }}$ and $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]_{\text {init }}$, which then dissociate to an unknown extent. We set up two reaction tables. The first summarizes the stoichiometry of adding strong base $(0.020 \mathrm{~mol})$ or acid $(0.020 \mathrm{~mol})$. The second summarizes the dissociation of the new HA concentrations, so we proceed as in part (a) to find the new $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$.
SOLUTION (a) The original $\mathrm{pH}:\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$in the original buffer.
Setting up a reaction table with $x=\left[\mathrm{CH}_{3} \mathrm{COOH}\right]_{\text {dissoc }}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$(as in Chapter 18, we assume that $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$from $\mathrm{H}_{2} \mathrm{O}$ is negligible and disregard it):

| Concentration $(M)$ | $\mathrm{CH}_{3} \mathrm{COOH}(a q)$ | + | $\mathrm{H}_{2} \mathrm{O}(l)$ | $\rightleftharpoons$ | $\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Initial | 0.50 | - | $\mathrm{H}_{3} \mathrm{O}^{+}(a q)$ |  |  |
| Change | $-x$ | - | 0.50 | 0 |  |
| Equilibrium | $0.50-x$ | - |  | $+x$ | $+x$ |

Making the assumption and finding the equilibrium $\left[\mathrm{CH}_{3} \mathrm{COOH}\right]$ and $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]$: With $K_{\mathrm{a}}$ small, $x$ is small, so we assume
$\left[\mathrm{CH}_{3} \mathrm{COOH}\right]=0.50 \mathrm{M}-x \approx 0.50 \mathrm{M}$ and $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]=0.50 \mathrm{M}+x \approx 0.50 \mathrm{M}$
Solving for $x\left(\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\right.$at equilibrium $)$:

$$
x=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=K_{\mathrm{a}} \times \frac{\left[\mathrm{CH}_{3} \mathrm{COOH}\right]}{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]} \approx\left(1.8 \times 10^{-5}\right) \times \frac{0.50}{0.50}=1.8 \times 10^{-5} \mathrm{M}
$$

Checking the assumption:

$$
\frac{1.8 \times 10^{-5} M}{0.50 M} \times 100=3.6 \times 10^{-3} \%<5 \%
$$

The assumption is justified, and we will use the same assumption in parts (b) and (c).
Calculating pH :

$$
\mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=-\log \left(1.8 \times 10^{-5}\right)=4.74
$$

(b) The pH after adding base $(0.020 \mathrm{~mol}$ of NaOH to 1.0 L of buffer $)$. Finding $\left[\mathrm{OH}^{-}\right]_{\text {added }}$ :

$$
\left[\mathrm{OH}^{-}\right]_{\mathrm{added}}=\frac{0.020 \mathrm{~mol} \mathrm{OH}^{-}}{1.0 \mathrm{~L} \text { soln }}=0.020 \mathrm{M} \mathrm{OH}^{-}
$$

Setting up a reaction table for the stoichiometry of adding $\mathrm{OH}^{-}$to $\mathrm{CH}_{3} \mathrm{COOH}$ :

| Concentration $(M)$ | $\mathrm{CH}_{3} \mathrm{COOH}(a q)$ | $+\mathrm{OH}^{-}(a q)$ | $\longrightarrow$ | $\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)$ | + |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Initial | 0.50 | 0.020 |  | 0.50 | - |
| Change | -0.020 | -0.020 |  | +0.020 | - |
| Final | 0.48 | 0 |  | 0.52 | - |

Setting up a reaction table for the acid dissociation, using these new initial concentrations. As in part (a), $x=\left[\mathrm{CH}_{3} \mathrm{COOH}\right]_{\text {dissoc }}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$:

| Concentration $(M)$ | $\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})$ | $+\mathrm{H}_{\mathbf{2}} \mathrm{O}(l)$ | $\rightleftharpoons$ | $\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})$ | + |
| :--- | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ |  |  |  |  |  |
| Initial | 0.48 | - |  | 0.52 | 0 |
| Change | $-x$ | - |  | $+x$ | $+x$ |
| Equilibrium | $0.48-x$ | - |  | $0.52+x$ | $x$ |

Making the assumption that $x$ is small, and solving for $x$ :
$\left[\mathrm{CH}_{3} \mathrm{COOH}\right]=0.48 M-x \approx 0.48 \mathrm{M}$ and $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]=0.52 M+x \approx 0.52 \mathrm{M}$

$$
x=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=K_{\mathrm{a}} \times \frac{\left[\mathrm{CH}_{3} \mathrm{COOH}\right]}{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]} \approx\left(1.8 \times 10^{-5}\right) \times \frac{0.48}{0.52}=1.7 \times 10^{-5} \mathrm{M}
$$

Calculating the pH :

$$
\begin{aligned}
\mathrm{pH} & =-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=-\log \left(1.7 \times 10^{-5}\right) \\
& =4.77
\end{aligned}
$$

The addition of strong base increased the concentration of the basic buffer component at the expense of the acidic buffer component. Note especially that the pH increased only slightly, from 4.74 to 4.77 .
(c) The pH after adding acid $\left(0.020 \mathrm{~mol}\right.$ of HCl to 1.0 L of buffer). Finding $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {added }}$ :

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]_{\text {added }}=\frac{0.020 \mathrm{~mol} \mathrm{H}_{3} \mathrm{O}^{+}}{1.0 \mathrm{~L} \mathrm{soln}}=0.020 \mathrm{M} \mathrm{H}_{3} \mathrm{O}^{+}
$$

Now we proceed as in part (b), by first setting up a reaction table for the stoichiometry of adding $\mathrm{H}_{3} \mathrm{O}^{+}$to $\mathrm{CH}_{3} \mathrm{COO}^{-}$:

| Concentration $(M)$ | $\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)$ | + | $\mathrm{H}_{3} \mathbf{O}^{+}(a q) \longrightarrow \mathrm{CH}_{3} \mathrm{COOH}(a q)$ | + | $\mathrm{H}_{2} \mathbf{O}(l)$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Initial | 0.50 | 0.020 | 0.50 | - |  |
| Change | -0.020 | -0.020 | +0.020 | - |  |
| Final | 0.48 | 0 | 0.52 | - |  |

The reaction table for the acid dissociation, with $x=\left[\mathrm{CH}_{3} \mathrm{COOH}\right]_{\text {dissoc }}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$is

| Concentration $(M)$ | $\mathrm{CH}_{3} \mathrm{COOH}(a q)$ | + | $\mathrm{H}_{2} \mathrm{O}(l)$ | $\rightleftharpoons$ | $\mathrm{CH}_{3} \mathrm{COO}^{-}(a q)$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| nitial | 0.52 | - |  | $\mathrm{H}_{3} \mathrm{O}^{+}(a q)$ |  |
| Change | $-x$ | - |  | 0.48 | 0 |
| Equilibrium | $0.52-x$ | - |  | $0.48+x$ | $+x$ |

Making the assumption that $x$ is small, and solving for $x$ :

$$
\begin{aligned}
& {\left[\mathrm{CH}_{3} \mathrm{COOH}\right]=0.52 M-x \approx 0.52 \mathrm{M} \text { and }\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]=0.48 \mathrm{M}+x \approx 0.48 \mathrm{M}} \\
& x=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=K_{\mathrm{a}} \times \frac{\left[\mathrm{CH}_{3} \mathrm{COOH}\right]}{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]} \approx\left(1.8 \times 10^{-5}\right) \times \frac{0.52}{0.48}=2.0 \times 10^{-5} \mathrm{M} \\
& \text { Calculating the } \mathrm{pH} \text { : } \\
& \mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=-\log \left(2.0 \times 10^{-5}\right) \\
& =4.70
\end{aligned}
$$

The addition of strong acid increased the concentration of the acidic buffer component at the expense of the basic buffer component and lowered the pH only slightly, from 4.74 to 4.70 .
CHECK The changes in $\left[\mathrm{CH}_{3} \mathrm{COOH}\right]$ and $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]$occur in opposite directions in parts (b) and (c), which makes sense. The additions were of equal amounts, so the pH increase in (b) should equal the pH decrease in (c), within rounding.
COMMENT In part (a), we justified our assumption that $x$ can be neglected. Therefore, in parts (b) and (c), we could have used the "Final" values from the last line of the stoichiometry tables directly for the ratio of buffer components; that would have allowed us to dispense with a reaction table for the dissociation. In subsequent problems in this chapter, we will follow this simplified approach.
FOLLOW-UP PROBLEM 19.1 Calculate the pH of a buffer consisting of 0.50 M HF and $0.45 \mathrm{M} \mathrm{F}^{-}$(a) before and (b) after addition of 0.40 g of NaOH to 1.0 L of the buffer $\left(K_{\mathrm{a}}\right.$ of $\left.\mathrm{HF}=6.8 \times 10^{-4}\right)$.

## The Henderson-Hasselbalch Equation

For any weak acid, HA, the dissociation equation and $K_{\mathrm{a}}$ expression are

$$
\begin{gathered}
\mathrm{HA}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{A}^{-} \\
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}
\end{gathered}
$$

The key variable that determines $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$is the concentration ratio of acid species to base species, so rearranging to isolate $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$gives

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=K_{\mathrm{a}} \times \frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}
$$

Taking the negative common logarithm dasea0) OfDoth sidesgives

$$
-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=-\log K_{\mathrm{a}}-\log \left(\frac{[\mathrm{HA}]}{\left[\mathrm{A}^{-}\right]}\right)
$$

from which we obtain

$$
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}\right)
$$

(Note the inversion of the buffer-component concentration ratio when the sign of the logarithm is changed.) A key point we'll emphasize again later is that when $\left[\mathrm{A}^{-}\right]=[\mathrm{HA}]$, their ratio becomes 1 ; the $\log$ term then becomes 0 , and thus $\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}$.

Generalizing the previous equation for any conjugate acid-base pair gives the

## Henderson-Hasselbalch equation:

$$
\begin{equation*}
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{[\text { base }]}{[\text { acid }]}\right) \tag{19.1}
\end{equation*}
$$

This relationship allows us to solve directly for pH instead of having to calculate $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$first. For instance, by applying the Henderson-Hasselbalch equation in part (b) of Sample Problem 19.1, we could have found the pH of the buffer after the addition of NaOH as follows:

$$
\begin{aligned}
\mathrm{pH} & =\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right]}{\left[\mathrm{CH}_{3} \mathrm{COOH}\right]}\right) \\
& =4.74+\log \left(\frac{0.52}{0.48}\right)=4.77
\end{aligned}
$$

(We just derived the Henderson-Hasselbalch equation from fundamental definitions and simple algebra. Whenever possible, it's a good idea to derive simple relationships rather than having to memorize them.)

Figure 19.4 The relation between buffer capacity and pH change.
The four bars in the graph represent $\mathrm{CH}_{3} \mathrm{COOH} / \mathrm{CH}_{3} \mathrm{COO}^{-}$buffers with the same initial pH (4.74) but different component concentrations (labeled on or near each bar). When a given amount of strong base is added to each buffer, the pH increases. The length of the bar corresponds to the pH increase. Note that the more concentrated the buffer, the greater its capacity, and the smaller the pH change.

## Buffer Capacity and Buffer Range

As you've seen, a buffer resists a pH change as long as the concentrations of buffer components are large compared with the amount of strong acid or base added. Buffer capacity is a measure of this ability to resist pH change and depends on both the absolute and relative component concentrations.

In absolute terms, the more concentrated the components of a buffer, the greater the buffer capacity. In other words, you must add more $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$to a high-capacity (concentrated) buffer than to a low-capacity (dilute) buffer to obtain the same pH change. Conversely, adding the same amount of $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$to buffers of different capacities produces a smaller pH change in the higher capacity buffer (Figure 19.4). It's important to realize that the pH of a buffer is distinct from its buffer capacity. A buffer made of equal volumes of 1.0 M $\mathrm{CH}_{3} \mathrm{COOH}$ and $1.0 \mathrm{M} \mathrm{CH}_{3} \mathrm{COO}^{-}$has the same $\mathrm{pH}(4.74)$ as a buffer made of equal volumes of $0.10 \mathrm{M} \mathrm{CH}_{3} \mathrm{COOH}$ and $0.10 \mathrm{M}_{\mathrm{CH}}^{3} \mathrm{COO}^{-}$, but the more concentrated buffer has a much larger capacity for resisting a pH change.

Buffer capacity is also affected by the relative concentrations of the buffer components. As a buffer functions, the concentration of one component increases relative to the other. Because the ratio of these concentrations determines the pH , the less the ratio changes, the less the pH changes. For a given addition of acid or base, the buffer-component concentration ratio changes less when the concentrations are similar than when they are different. Suppose that a buffer has $[\mathrm{HA}]=\left[\mathrm{A}^{-}\right]=1.000 \mathrm{M}$. When we add 0.010 mol of $\mathrm{OH}^{-}$to 1.00 L of buffer, [ $\mathrm{A}^{-}$] becomes 1.010 M and [HA] becomes 0.990 M :

$$
\frac{\left[\mathrm{A}^{-}\right]_{\text {init }}}{[\mathrm{HA}]_{\text {nit }}}=\frac{1.000 \mathrm{M}}{1.000 \mathrm{M}}=1.000 \quad \frac{\left[\mathrm{~A}^{-}\right]_{\text {final }}}{[\mathrm{HA}]_{\text {final }}}=\frac{1.010 \mathrm{M}}{0.990 \mathrm{M}}=1.02
$$

## 

Now let us suppose that the component concentrations are [HA] $=0.250 \mathrm{M}$ and $\left[\mathrm{A}^{-}\right]=1.750 \mathrm{M}$. The same addition of 0.010 mol of $\mathrm{OH}^{-}$to 1.00 L of buffer gives $[\mathrm{HA}]=0.240 \mathrm{M}$ and $\left[\mathrm{A}^{-}\right]=1.760 \mathrm{M}$, so the ratios are

$$
\begin{gathered}
\frac{\left[\mathrm{A}^{-}\right]_{\text {init }}}{[\mathrm{HA}]_{\text {init }}}=\frac{1.750 M}{0.250 M}=7.00 \quad \frac{\left[\mathrm{~A}^{-}\right]_{\text {final }}}{[\mathrm{HA}]_{\text {final }}}=\frac{1.760 M}{0.240 M}=7.33 \\
\text { Percent change }=\frac{7.33-7.00}{7.00} \times 100=4.7 \%
\end{gathered}
$$

As you can see, the change in the buffer-component concentration ratio is much larger when the initial concentrations of the components are very different.

It follows that $a$ buffer has the highest capacity when the component concentrations are equal, that is, when $\left[\mathrm{A}^{-}\right] /[\mathrm{HA}]=1$ :

$$
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}\right)=\mathrm{p} K_{\mathrm{a}}+\log 1=\mathrm{p} K_{\mathrm{a}}+0=\mathrm{p} K_{\mathrm{a}}
$$

Note this important result: for a given concentration, a buffer whose pH is equal to or near the $\mathrm{p} K_{a}$ of its acid component has the highest buffer capacity.

The buffer range is the pH range over which the buffer acts effectively, and it is related to the relative component concentrations. The further the buffercomponent concentration ratio is from 1 , the less effective the buffering action (that is, the lower the buffer capacity). In practice, if the $\left[\mathrm{A}^{-}\right] /[\mathrm{HA}]$ ratio is greater than 10 or less than 0.1 -that is, if one component concentration is more than 10 times the other-buffering action is poor. Recalling that $\log 10=+1$ and $\log 0.1=-1$, we find that buffers have a usable range within $\pm 1 \mathrm{pH}$ unit of the $\mathrm{p} K_{a}$ of the acid component:

$$
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{10}{1}\right)=\mathrm{p} K_{\mathrm{a}}+1 \quad \text { and } \quad \mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{1}{10}\right)=\mathrm{p} K_{\mathrm{a}}-1
$$

SAMPLE PROBLEM 19.2 Using Molecular Scenes to Examine Buffers
PROBLEM The molecular scenes below represent samples of four HA/A ${ }^{-}$buffer solutions. (HA is blue and green, $\mathrm{A}^{-}$is green, and other ions and water are not shown.)

(a) Which buffer has the highest pH ?
(b) Which buffer has the greatest capacity?
(c) Should we add a small amount of concentrated strong acid or strong base to convert sample 1 to sample 2 (assuming no volume change)?
PLAN The molecular scenes show varying numbers of weak acid molecules (HA) and the conjugate base anion ( $\mathrm{A}^{-}$). Numbers correspond to moles and, because the volumes are equal, the scenes represent molarities as well. (a) As the pH rises, more HA donates its $\mathrm{H}^{+}$ and becomes $\mathrm{A}^{-}$, so the $\left[\mathrm{A}^{-}\right] /[\mathrm{HA}]$ ratio will increase. We examine the scenes to see which has the highest ratio. (b) Buffer capacity depends on buffer-component concentration and ratio. We examine the scenes to see which has a high concentration and a ratio close to 1 . (c) Adding strong acid converts some $\mathrm{A}^{-}$to HA, and adding strong base does the opposite. Comparing the $\left[\mathrm{A}^{-}\right] /[\mathrm{HA}]$ ratios in samples 1 and 2 tells us which to add.
SOLUTION (a) The $\left[\mathrm{A}^{-}\right] /[\mathrm{HA}]$ ratios are as follows: For sample $1,\left[\mathrm{~A}^{-}\right] /[\mathrm{HA}]=3 / 3=1$. Similarly, sample $2=0.5$; sample $3=1$; sample $4=2$. Sample 4 has the highest pH because it has the highest $\left[\mathrm{A}^{-}\right] /[\mathrm{HA}]$ ratio.
(b) Samples 1 and 3 have a $\left[\mathrm{A}^{-}\right] /[\mathrm{HA}]$ ratio of 1 , but sample 3 has the greater capacity because it has a higher concentration.
(c) Sample 2 has a lower $\left[\mathrm{A}^{-}\right] /[\mathrm{HA}]$ ratio than sample 1 , so we would add strong acid to sample 1 to convert some $\mathrm{A}^{-}$to HA.
FOLLOW-UP PROBLEM 19.2 The molecular scene (see margin) shows a sample of an $\mathrm{HB} / \mathrm{B}^{-}$buffer solution. ( HB is blue and yellow, $\mathrm{B}^{-}$is yellow, and other ions and water are not shown.) (a) Would you add a small amount of concentrated strong acid or strong base to increase the buffer capacity? (b) Assuming no volume change, draw a scene that represents the buffer with the highest possible capacity after the addition in part (a).

## Preparing a Buffer

Any large chemical supply-house catalog lists many common buffers in a variety of pH values and concentrations. So, you might ask, why learn how to prepare a buffer? In many cases, a common buffer is simply not available with the desired pH or concentration, and you have to make it yourself. In many environmental or biomedical research applications, a buffer of unusual composition may be required to simulate an ecosystem or stabilize a fragile biological macromolecule. Even the most sophisticated, automated laboratory frequently relies on personnel with a good knowledge of basic chemistry to prepare a buffer. Several steps are required to prepare a buffer of a desired pH :

1. Choose the conjugate acid-base pair. First, decide on the chemical composition of the buffer, that is, the conjugate acid-base pair. This choice is determined to a large extent by the desired pH . Remember that a buffer is most effective when the ratio of its component concentrations is close to 1 , in which case the $\mathrm{pH} \approx \mathrm{p} K_{\mathrm{a}}$ of the acid.

Suppose that, for a biochemical experiment, you need a buffer whose pH is 3.90: the $\mathrm{p} K_{\mathrm{a}}$ of the acid component should be as close to 3.90 as possible; or $K_{\mathrm{a}}=10^{-3.90}=1.3 \times 10^{-4}$. A table of acid-dissociation constants (see Appendix C) shows that lactic acid ( $\mathrm{p} K_{\mathrm{a}}=3.86$ ), glycolic acid ( $\mathrm{p} K_{\mathrm{a}}=3.83$ ), and formic acid $\left(\mathrm{p} K_{\mathrm{a}}=3.74\right)$ are good choices. To avoid common biological species, you use
formic acid. Therefore, the buffer components will be formic acid, HCOOH , and formate ion, $\mathrm{HCOO}^{-}$, supplied by a soluble salt, such as sodium formate, HCOONa.
2. Calculate the ratio of buffer component concentrations. Next, find the ratio of $\left[\mathrm{A}^{-}\right] /[\mathrm{HA}]$ that gives the desired pH . With the Henderson-Hasselbalch equation, we have

$$
\begin{array}{lll}
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{\left[\mathrm{A}^{-}\right]}{[\mathrm{HA}]}\right) & \text { or } & 3.90=3.74+\log \left(\frac{\left[\mathrm{HCOO}^{-}\right]}{[\mathrm{HCOOH}]}\right) \\
\log \left(\frac{\left[\mathrm{HCOO}^{-}\right]}{[\mathrm{HCOOH}]}\right)=0.16 & \text { so } & \left(\frac{\left[\mathrm{HCOO}^{-}\right]}{[\mathrm{HCOOH}]}\right)=10^{0.16}=1.4
\end{array}
$$

Thus, for every 1.0 mol of HCOOH in a given volume of solution, you need 1.4 mol of HCOONa .
3. Determine the buffer concentration. Next, decide how concentrated the buffer should be. Remember that the higher the concentrations of components, the greater the buffer capacity. For most laboratory-scale applications, concentrations of about 0.5 M are suitable, but the decision is often based on availability of stock solutions.

Suppose you have a large stock of 0.40 M HCOOH and you need approximately 1.0 L of final buffer. First, find the moles of sodium formate that will give the needed 1.4/1.0 ratio, and then convert to grams:

$$
\begin{aligned}
& \text { Moles of } \mathrm{HCOOH}=1.0 \mathrm{~L} \text { soln } \times \frac{0.40 \mathrm{~mol} \mathrm{HCOOH}}{1.0 \mathrm{~L} \text { soln }}=0.40 \mathrm{~mol} \mathrm{HCOOH} \\
& \text { Moles of } \mathrm{HCOONa}=0.40 \mathrm{~mol} \mathrm{HCOOH} \times \frac{1.4 \mathrm{~mol} \mathrm{HCOONa}}{1.0 \mathrm{~mol} \mathrm{HCOOH}}=0.56 \mathrm{~mol} \mathrm{HCOONa}
\end{aligned}
$$

$$
\text { Mass(g) \& } \mathrm{HCOONa}=0.56 \mathrm{mofHCOONa} * \frac{68.01 \mathrm{~g} \mathrm{HCOONa}}{1 \mathrm{~mol} \mathrm{HCOONa}}=38 \mathrm{~g} \mathrm{HCOONa}
$$

4. Mix the solution and adjust the $p H$. Thoroughly dissolve 38 g of solid sodium formate in 0.40 M HCOOH to a total volume of 1.0 L . Finally, note that because of the behavior of nonideal solutions (Section 13.6), a buffer prepared in this way may vary from the desired pH by a few tenths of a pH unit. Therefore, after making up the solution, adjust the buffer pH to the desired value by adding strong acid or strong base, while monitoring the solution with a pH meter. (The following sample problem does not refer to the Henderson-Hasselbalch equation.)

## SAMPLE PROBLEM 19.3 Preparing a Buffer

PROBLEM An environmental chemist needs a carbonate buffer of pH 10.00 to study the effects of the acid rain on limestone-rich soils. How many grams of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ must she add to 1.5 L of freshly prepared 0.20 M NaHCO 3 to make the buffer? $K_{\mathrm{a}}$ of $\mathrm{HCO}_{3}{ }^{-}$is $4.7 \times 10^{-11}$.
PLAN The conjugate pair is already chosen, $\mathrm{HCO}_{3}{ }^{-}$(acid) and $\mathrm{CO}_{3}{ }^{2-}$ (base), as are the volume $(1.5 \mathrm{~L})$ and concentration $(0.20 \mathrm{M})$ of $\mathrm{HCO}_{3}{ }^{-}$, so we must find the buffercomponent concentration ratio that gives pH 10.00 and the mass of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ to dissolve. We first convert pH to $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and use the $K_{\mathrm{a}}$ expression from the equation to solve for the required $\left[\mathrm{CO}_{3}{ }^{2-}\right]$. Multiplying by the volume of solution gives the amount (mol) of $\mathrm{CO}_{3}{ }^{2-}$ required, and then we use the molar mass to find the mass (g) of $\mathrm{Na}_{2} \mathrm{CO}_{3}$. SOLUTION Calculating $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]:\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-\mathrm{pH}}=10^{-10.00}=1.0 \times 10^{-10} \mathrm{M}$ Solving for $\left[\mathrm{CO}_{3}{ }^{2-}\right]$ in the concentration ratio:

So

$$
\begin{aligned}
& \mathrm{HCO}_{3}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{CO}_{3}^{2-}(a q) \quad K_{\mathrm{a}} \\
&=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{CO}_{3}{ }^{2-}\right]}{\left[\mathrm{HCO}_{3}^{-}\right]} \\
& {\left[\mathrm{CO}_{3}^{2-}\right] }=K_{\mathrm{a}} \frac{\left[\mathrm{HCO}_{3}^{-}\right]}{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}=\frac{\left(4.7 \times 10^{-11}\right)(0.20)}{1.0 \times 10^{-10}}=0.094 \mathrm{M}
\end{aligned}
$$

Calculating the amount (mol) of $\mathrm{CO}_{3}{ }^{2-}$ needed for the given volume:

$$
\text { Moles of } \mathrm{CO}_{3}{ }^{2-}=1.5 \mathrm{~L} \text { soln } \times \frac{0.094 \mathrm{~mol} \mathrm{CO}_{3}^{2-}}{1 \mathrm{~L} \text { soln }}=0.14 \mathrm{~mol} \mathrm{CO}_{3}{ }^{2-}
$$

Calculating the mass $(\mathrm{g})$ of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ needed:

$$
\text { Mass }(\mathrm{g}) \text { of } \mathrm{Na}_{2} \mathrm{CO}_{3}=0.14 \mathrm{~mol} \mathrm{Na}_{2} \mathrm{CO}_{3} \times \frac{105.99 \mathrm{~g} \mathrm{Na}_{2} \mathrm{CO}_{3}}{1 \mathrm{~mol} \mathrm{Na}_{2} \mathrm{CO}_{3}}=15 \mathrm{~g} \mathrm{Na}_{2} \mathrm{CO}_{3}
$$

We dissolve 15 g of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ into 1.3 L of $0.20 \mathrm{M} \mathrm{NaHCO}_{3}$ and add $0.20 \mathrm{MaHCO}_{3}$ to make 1.5 L . Using a pH meter, we adjust the pH to 10.00 with strong acid or base. CHECK For a useful buffer range, the concentration of the acidic component, $\left[\mathrm{HCO}_{3}{ }^{-}\right]$, must be within a factor of 10 of the concentration of the basic component, $\left[\mathrm{CO}_{3}{ }^{2-}\right]$. We have $(1.5 \mathrm{~L})\left(0.20 \mathrm{M} \mathrm{HCO}_{3}{ }^{-}\right)$, or 0.30 mol of $\mathrm{HCO}_{3}{ }^{-}$, and 0.14 mol of $\mathrm{CO}_{3}{ }^{2-}$; $0.30 / 0.14=2.1$, which seems fine. Make sure the relative amounts of components seem reasonable: since we want a pH lower than the $\mathrm{p} K_{\mathrm{a}}$ of $\mathrm{HCO}_{3}{ }^{-}$(10.33), it makes sense that we have more of the acidic than the basic species.
FOLLOW-UP PROBLEM 19.3 How would you prepare a benzoic acid/benzoate buffer with $\mathrm{pH}=4.25$, starting with 5.0 L of 0.050 M sodium benzoate $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COONa}\right)$ solution and adding the acidic component? $K_{\mathrm{a}}$ of benzoic acid $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}\right)$ is $6.3 \times 10^{-5}$.

Another way to prepare a buffer is to form one of the components during the final mixing step by partial neutralization of the other component. For example, you can prepare an $\mathrm{HCOOH} / \mathrm{HCOO}^{-}$buffer by mixing appropriate amounts of HCOOH solution and NaOH solution. As the $\mathrm{OH}^{-}$ions react with the HCOOH molecules, neutralization of part of the total HCOOH present produces the $\mathrm{HCOO}^{-}$needed:
$\mathrm{HCOOH}(\mathrm{HA}$ total $)+\mathrm{OH}^{-}($amt added)
$\mathrm{HCOOH}\left(\mathrm{HA}\right.$ total $-\mathrm{OH}^{-}$amt added $)+\mathrm{HCOO}^{-}\left(\mathrm{OH}^{-}\right.$amt added $)+\mathrm{H}_{2} \mathrm{O}$
This method is based on the same chemical process that occurs when a weak acid is titrated with a strong base, as you'll see in Section 19.2.

## Section Summary

A buffered solution exhibits a much smaller change in pH when $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$ is added than does an unbuffered solution. - A buffer consists of relatively high concentrations of the components of a conjugate weak acid-base pair. The buffercomponent concentration ratio determines the pH , and the ratio and pH are related by the Henderson-Hasselbalch equation. As $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$is added, one buffer component reacts with it and is converted into the other component; therefore, the buffer-component concentration ratio, and consequently the free $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$(and pH ), changes only slightly. - A concentrated buffer undergoes smaller changes in pH than a dilute buffer. When the buffer pH equals the $\mathrm{p} K_{\mathrm{a}}$ of the acid component, the buffer has its highest capacity. - A buffer has an effective range of $\mathrm{p} K_{\mathrm{a}} \pm 1 \mathrm{pH}$ unit. - To prepare a buffer, choose the conjugate acid-base pair, calculate the ratio of buffer components, determine buffer concentration, and adjust the final solution to the desired pH .

### 19.2 ACID-BASE TITRATION CURVES

In Chapter 4, we discussed the acid-base titration as an analytical method. Let's re-examine it, this time tracking the change in pH with an acid-base titration curve, a plot of pH vs. volume of titrant added. The behavior of an acid-base indicator and its role in the titration are described first. To better understand the titration process, we apply the principles of the acid-base behavior of salt solutions (Section 18.7) and, later in the section, the principles of buffer action.

Figure 19.5 Colors and approximate pH range of some common acid-base indicators. Most have a range of about 2 pH units, in
keeping with the useful buffer range of 2 pH units ( $\mathrm{p} K_{\mathrm{a}} \pm 1$ ). ( pH range depends to some extent on the solvent used to prepare the indicator.)

Figure 19.6 The color change of the indicator bromthymol blue. The acidic form of bromthymol blue is yellow (left) and the basic form is blue (right). Over the pH range in which the indicator is changing, both forms are present, so the mixture appears greenish (center).

## Monitoring pH with Acid-Base Indicators

The two common devices for measuring pH in the laboratory are pH meters and acid-base indicators. (We discuss the operation of pH meters in Chapter 21.) An aqid-bas indicatorisa weak grganic acid (denoted here as HIn) that has a different cobr than its conjugate base (In), with the color change occurring over a specific and relatively narrow pH range. Typically, one or both of the forms are intensely colored, so only a tiny amount of indicator is needed, far too little to affect the pH of the solution being studied.

Indicators are used for estimating the pH of a solution and for monitoring the pH in acid-base titrations and in reactions. Figure 19.5 shows the color changes and their pH ranges for some common acid-base indicators. Selecting an indicator requires that you know the approximate pH of the titration end point, which in turn requires that you know which ionic species are present. You'll see how to identify those in our discussion of acid-base titration curves. Because the indicator molecule is a weak acid, the ratio of the two forms is governed by the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$ of the test solution:

$$
\mathrm{HIn}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{In}^{-}(a q) \quad K_{\mathrm{a}} \text { of } \mathrm{HIn}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{In}^{-}\right]}{[\mathrm{HIn}]}
$$

Therefore,

$$
\frac{[\mathrm{HIn}]}{\left[\mathrm{In}^{-}\right]}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}{K_{\mathrm{a}}}
$$

How we perceive colors has a major influence on the use of indicators. Typically, the experimenter will see the HIn color if the $[\mathrm{HIn}] /\left[\mathrm{In}^{-}\right]$ratio is $10 / 1$ or greater and the $\mathrm{In}^{-}$color if the $[\mathrm{HIn}] /\left[\mathrm{In}^{-}\right]$ratio is $1 / 10$ or less. Between these extremes, the colors of the two forms merge into an intermediate hue. Therefore, an indicator has a color range that reflects a $10^{2}$-fold range in the [HIn]/[In] ratio, which means that an indicator changes color over a range of about 2 pH units. For example, as you can see in Figure 19.5, bromthymol blue has a pH range of about 6.0 to 7.6 and, as Figure 19.6 shows, it is yellow below that range, blue above it, and greenish in between.

## Strong Acid-Strong Base Titration Curves

A typical curve for the titration of a strong acid with a strong base appears in Figure 19.7, along with the data used to construct it.
Features of the Curve There are three distinct regions of the curve, which correspond to three major changes in slope:

1. The pH starts out low, reflecting the high $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$of the strong acid, and increases slowly as acid is gradually neutralized by the added base.
2. Suddenly, the pH rises steeply. This rise begins when the moles of $\mathrm{OH}^{-}$that have been added nearly equal the moles of $\mathrm{H}_{3} \mathrm{O}^{+}$originally present in the acid. An additional drop or two of base neutralizes the final tiny excess of acid and introduces a tiny excess of base, so the pH jumps 6 to 8 units.
3. Beyond this steep portion, the pH increases slowly as more base is added.

The equivalence point, which occurs within the nearly vertical portion of the curve, is the point at which the number of moles of added $\mathrm{OH}^{-}$equals the number of moles of $\mathrm{H}_{3} \mathrm{O}^{+}$originally present. At the equivalence point of a strong acid-strong base titration, the solution consists of the anion of the strong acid and the cation of the strong base. Recall from Chapter 18 that these ions do not react with water, so the solution is neutral: $p H=7.00$. The volume and concentration of base needed to reach the equivalence point allow us to calculate the amount of acid originally present (see Sample Problem 4.6, p. 154).

Before the titration begins, we add a few drops of an appropriate indicator to the acid solution to signal when we reach the equivalence point. The end point of the titration occurs when the indicator changes color. We choose an indicator with an end point close to the equivalence point, one that changes color in the pH range on the steep vertical portion of the curve. Figure 19.7 shows the color changes for two indicators that are suitable for a strong acid-strong base titration. Methyl red changes from red at pH 4.2 to yellow at pH 6.3 , whereas phenolphthalein changes from colorless at pH 8.3 to pink at pH 10.0. Even though neither color change occurs at the equivalence point ( pH 7.00 ), both occur on the vertical portion of the curve, where a single drop of base causes a large pH change: when methyl red turns yellow, or when phenolphthalein turns pink, we know we are within a drop or two of the equivalence point. For example, in going from 39.90 to 39.99 mL , one to two drops, the pH changes one whole unit. For all practical purposes, then, the visible change in color of the indicator (end point) signals the invisible point at which moles of added base equal the original moles of acid (equivalence point).
Calculating the pH By knowing the chemical species present during the titration, we can calculate the pH at various points along the way:

1. Original solution of strong HA. In Figure 19.7, 40.00 mL of 0.1000 M HCl is titrated with 0.1000 M NaOH . Because a strong acid is completely dissociated, $[\mathrm{HCl}]=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=0.1000 \mathrm{M}$. Therefore, the initial pH is*

$$
\mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=-\log (0.1000)=1.00
$$

2. Before the equivalence point. As soon as we start adding base, two changes occur that affect the pH calculations: (1) some acid is neutralized, and (2) the volume of solution increases. To find the pH at various points up to the equivalence peint we find the initial mont mol) of $\mathrm{H}_{3} \mathrm{O}^{+}$present, subtract the amount reacted, wioh equals the amount (mol) of $\mathrm{OH}^{-}$added, and then use the change in volume to calculate the concentration, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$, and convert to pH . For example, after adding 20.00 mL of 0.1000 M NaOH :

- Find the moles of $\mathrm{H}_{3} \mathrm{O}^{+}$remaining. Subtracting the number of moles of $\mathrm{H}_{3} \mathrm{O}^{+}$ reacted from the number initially present gives the number remaining. Moles of $\mathrm{H}_{3} \mathrm{O}^{+}$reacted equals moles of $\mathrm{OH}^{-}$added, so

$$
\begin{aligned}
& \text { Initial moles of } \mathrm{H}_{3} \mathrm{O}^{+}=0.04000 \mathrm{~L} \times 0.1000 \mathrm{M}=0.004000 \mathrm{~mol} \mathrm{H}_{3} \mathrm{O}^{+} \\
& - \text {Moles of } \mathrm{OH}^{-} \text {added }=0.02000 \mathrm{~L} \times 0.1000 \mathrm{M}=0.002000 \mathrm{~mol} \mathrm{OH}^{-}
\end{aligned}
$$

- Calculate $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$, taking the total volume into account. To find the ion concentrations, we use the total volume because the water of one solution dilutes the ions of the other:

$$
\begin{aligned}
{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] } & =\frac{\text { amount }(\mathrm{mol}) \text { of } \mathrm{H}_{3} \mathrm{O}^{+} \text {remaining }}{\text { original volume of acid }+ \text { volume of added base }} \\
& =\frac{0.002000 \mathrm{~mol} \mathrm{H}_{3} \mathrm{O}^{+}}{0.04000 \mathrm{~L}+0.02000 \mathrm{~L}}=0.03333 \mathrm{M} \quad \mathrm{pH}=1.48
\end{aligned}
$$

Given the moles of $\mathrm{OH}^{-}$added, we are halfway to the equivalence point; but we are still on the initial slow rise of the curve, so the pH is still very low. Similar calculations give values up to the equivalence point.
3. At the equivalence point. After 40.00 mL of 0.1000 M NaOH has been added, the equivalence point is reached. All the $\mathrm{H}_{3} \mathrm{O}^{+}$from the acid has been

[^29]neutralized, and the solution contains $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$, neither of which reacts with water. Because of the autoionization of water, however,
$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=1.0 \times 10^{-7} M \quad \mathrm{pH}=7.00
$$

In this example, 0.004000 mol of $\mathrm{OH}^{-}$reacted with 0.004000 mol of $\mathrm{H}_{3} \mathrm{O}^{+}$to reach the equivalence point.
4. After the equivalence point. From the equivalence point on, the pH calculation is based on the moles of excess $\mathrm{OH}^{-}$present. For example, after adding 50.00 mL of NaOH , we have

$$
\begin{gathered}
\begin{array}{c}
\text { Total moles of } \mathrm{OH}^{-} \text {added }=0.05000 \mathrm{~L} \times 0.1000 \mathrm{M}=0.005000 \mathrm{~mol} \mathrm{OH}^{-} \\
- \text {Moles of } \mathrm{H}_{3} \mathrm{O}^{+} \text {consumed }=0.04000 \mathrm{~L} \times 0.1000 \mathrm{M}=0.004000 \mathrm{~mol} \mathrm{H}_{3} \mathrm{O}^{+} \\
\hline \text { Moles of excess } \mathrm{OH}^{-}= \\
{\left[\mathrm{OH}^{-}\right]=\frac{0.001000 \mathrm{~mol} \mathrm{OH}}{}{ }^{-}} \\
0.04000 \mathrm{~L}+0.05000 \mathrm{~L}
\end{array}=0.01111 \mathrm{M} \quad \mathrm{pOH}=1.95 \\
\mathrm{pH}=\mathrm{p} K_{\mathrm{w}}-\mathrm{pOH}=14.00-1.95=12.05
\end{gathered}
$$

## Weak Acid-Strong Base Titration Curves

Now let's turn to the titration of a weak acid with a strong base. Figure 19.8 shows the curve obtained when we use 0.1000 M NaOH to titrate 40.00 mL of 0.1000 M propanoic acid, a weak organic acid $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{COOH} ; K_{\mathrm{a}}=1.3 \times 10^{-5}\right)$. (We abbreviate the acid as HPr and the conjugate base, $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{COO}^{-}$, as $\mathrm{Pr}^{-}$.)

Figure 19.8 Curve for a weak acidstrong base titration. The curve for the titration of 40.00 mL of 0.1000 M $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{COOH}$ (HPr) with 0.1000 M NaOH is compared with that for the strong acid HCl (dotted portion). Note the buffer region and the equivalence point, which is above pH 7 , as indicated by the change in color of phenolphthalein (photo). The blow-up circles depict the relative numbers of species present at key points during the titration.

Features of the Curve When we compare this weak acid-strong base titration curve with the strong acid-strong base titration curve (dotted curve portion in Figure 19.8 corresponds to bottom half of curve in Figure 19.7), four key regions appear, and the first three differ from the strong acid case:

1. The initial pH is higher. Because the weak acid (HPr) dissociates slightly, much less $\mathrm{H}_{3} \mathrm{O}^{+}$is present than with the strong acid.
2. A gradually rising portion of the curve, called the buffer region, appears before the steep rise to the equivalence point. As HPr reacts with the strong base, more and more conjugate base ( $\mathrm{Pr}^{-}$) forms, which creates an $\mathrm{HPr} / \mathrm{Pr}^{-}$buffer. At the midpoint of the buffer region, half the original HPr has reacted, so $[\mathrm{HPr}]=\left[\mathrm{Pr}^{-}\right]$, or $\left[\mathrm{Pr}^{-}\right] /[\mathrm{HPr}]=1$. Therefore, the pH equals the $\mathrm{p} K_{\mathrm{a}}$ :

$$
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{\left[\mathrm{Pr}^{-}\right]}{[\mathrm{HPr}]}\right)=\mathrm{p} K_{\mathrm{a}}+\log 1=\mathrm{p} K_{\mathrm{a}}+0=\mathrm{p} K_{\mathrm{a}}
$$

Observing the pH at the midpoint of the buffer region is a common method for estimating the $\mathrm{p} K_{\mathrm{a}}$ of an unknown acid.
3. The pH at the equivalence point is greater than 7.00. The solution contains the strong-base cation $\mathrm{Na}^{+}$, which does not react with water, and the weak-acid anion $\mathrm{Pr}^{-}$, which acts as a weak base to accept a proton from $\mathrm{H}_{2} \mathrm{O}$ and yield $\mathrm{OH}^{-}$.
4. Beyond the equivalence point, the pH increases slowly as excess $\mathrm{OH}^{-}$is added.

Our choice of indicator is more limited here than for a strong acid-strong base titration because the steep rise occurs over a smaller pH range. Phenolphthalein is suitable because its color change lies within this range (Figure 19.8). However, the figure shows that methyl red, our other choice for the strong acid-strong base titration, changes color earlier and slowly over a large volume $(\sim 10 \mathrm{~mL})$ of titrant, thereby giving a vague and false indication of the equivalence point.
Câculating the PHDThe catcuaton proce fue for the weak acid-strong base titration is different from that for the strong acid-strong base titration because we have to consider the partial dissociation of the weak acid and the reaction of the conjugate base with water. There are four key regions of the titration curve, each of which requires a different type of calculation to find $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$:

1. Solution of $H A$. Before base is added, the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$is that of a weak-acid solution, so we find $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$as in Section 18.4: we set up a reaction table with $x=[\mathrm{HPr}]_{\text {dissoc }}$, assume $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=[\mathrm{HPr}]_{\text {dissoc }} \ll[\mathrm{HPr}]_{\text {init }}$, and solve for $x$ :

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{Pr}^{-}\right]}{[\mathrm{HPr}]} \approx \frac{x^{2}}{[\mathrm{HPr}]_{\mathrm{init}}} \quad \text { therefore, } \quad x=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \approx \sqrt{K_{\mathrm{a}} \times[\mathrm{HPr}]_{\text {init }}}
$$

2. Solution of HA and added base. As soon as we add NaOH , it reacts with HPr to form $\mathrm{Pr}^{-}$. This means that up to the equivalence point, we have a mixture of acid and conjugate base, and an $\mathrm{HPr} / \mathrm{Pr}^{-}$buffer solution exists over much of that interval. Therefore, we find $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$from the relationship

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=K_{\mathrm{a}} \times \frac{[\mathrm{HPr}]}{\left[\mathrm{Pr}^{-}\right]}
$$

(Of course, we can find pH directly with the Henderson-Hasselbalch equation, which is just an alternative form of this relationship.) Note that in this calculation we do not have to consider the new total volume because the volumes cancel in the ratio of concentrations. That is, $[\mathrm{HPr}] /\left[\mathrm{Pr}^{-}\right]=$moles of $\mathrm{HPr} /$ moles of $\mathrm{Pr}^{-}$, so we need not calculate concentrations.
3. Equivalent amounts of HA and added base. At the equivalence point, the original amount of HPr has reacted, so the flask contains a solution of $\mathrm{Pr}^{-}$, a weak base that reacts with water to form $\mathrm{OH}^{-}$:

$$
\operatorname{Pr}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HPr}(a q)+\mathrm{OH}^{-}(a q)
$$

Therefore, as mentioned previously, in a weak acid-strong base titration, the solution at the equivalence point is slightly basic, $\mathrm{pH}>7.00$. We calculate $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$ as in Section 18.5: we first find $K_{\mathrm{b}}$ of $\operatorname{Pr}^{-}$from $K_{\mathrm{a}}$ of HPr , set up a reaction table (assume $\left[\mathrm{Pr}^{-}\right] \gg\left[\mathrm{Pr}^{-}\right]_{\text {reacting }}$ ), and solve for $\left[\mathrm{OH}^{-}\right]$. We need a single concentration, $\left[\mathrm{Pr}^{-}\right]$, to solve for $\left[\mathrm{OH}^{-}\right]$, so we do need the total volume. Then, we convert to $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$. These two steps are
(1) $\left[\mathrm{OH}^{-}\right] \approx \sqrt{K_{\mathrm{b}} \times\left[\mathrm{Pr}^{-}\right]}$, where $K_{\mathrm{b}}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}}}$ and $\left[\mathrm{Pr}^{-}\right]=\frac{\text { moles of } \mathrm{HPr}_{\text {init }}}{\text { total volume }}$
(2) $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\frac{K_{\mathrm{w}}}{\left[\mathrm{OH}^{-}\right]}$

Combining them into one step gives

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \approx \frac{K_{\mathrm{w}}}{\sqrt{K_{\mathrm{b}} \times\left[\mathrm{Pr}^{-}\right]}}
$$

4. Solution of excess added base. Beyond the equivalence point, we are just adding excess $\mathrm{OH}^{-}$ion, so the calculation is the same as for the strong acid-strong base titration:

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\frac{K_{\mathrm{w}}}{\left[\mathrm{OH}^{-}\right]}, \quad \text { where }\left[\mathrm{OH}^{-}\right]=\frac{\text { moles of excess } \mathrm{OH}^{-}}{\text {total volume }}
$$

Sample Problem 19.4 shows the overall approach.

## SAMPLE PROBLEM 19.4 Finding the pH During a Weak AcidStrong Base Titration

PROBLEM Calculate the pH during the titration of 40.00 mL of 0.1000 M propanoic acid $\left(\mathrm{HPr} ; K_{\mathrm{a}}=1.3 \times 10^{-5}\right)$ after each of the following volumes of 0.1000 M NaOH has been added:
(a) 0.00 mL
(b) 30.00 mL
(c) 40.00 mL
(d) 50.00 mL

PLAN (a) 0.00 mL : No base has been added yet, so this is a weak-acid solution. Thus, we calculate the pH as we did in Section 18.4. (b) 30.00 mL : A mixture of $\mathrm{Pr}^{-}$and HPr is present. We find the amount (mol) of each, substitute into the $K_{\mathrm{a}}$ expression to solve for $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$, and convert to pH . (c) 40.00 mL : The amount (mol) of NaOH added equals the initial amount (mol) of HPr, so a solution of $\mathrm{Na}^{+}$and the weak base $\mathrm{Pr}^{-}$exists. We calculate the pH as we did in Section 18.5, except that we need total volume to find $\left[\mathrm{Pr}^{-}\right]$. (d) 50.00 mL : Excess NaOH is added, so we calculate the amount (mol) of excess $\mathrm{OH}^{-}$ in the total volume and convert to $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and then pH .
SOLUTION (a) 0.00 mL of 0.1000 M NaOH added. Following the approach used in Sample Problem 18.8 and just described in the text, we obtain

$$
\begin{aligned}
& {\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \approx \sqrt{K_{\mathrm{a}} \times[\mathrm{HPr}]_{\text {init }}}=\sqrt{\left(1.3 \times 10^{-5}\right)(0.1000)}=1.1 \times 10^{-3} M} \\
& \quad \mathrm{pH}=2.96
\end{aligned}
$$

(b) 30.00 mL of 0.1000 M NaOH added. Calculating the ratio of moles of HPr to $\mathrm{Pr}^{-}$:

$$
\begin{aligned}
\text { Original moles of } \mathrm{HPr} & =0.04000 \mathrm{~L} \times 0.1000 M \\
\text { Moles of } \mathrm{NaOH} \text { added } & =0.03000 \mathrm{~L} \times 0.1000 M
\end{aligned}=0.003000 \mathrm{~mol} \mathrm{HPr}^{-2} \mathrm{~mol}^{-}-2 .
$$

For 1 mol of NaOH that reacts, 1 mol of $\mathrm{Pr}^{-}$forms, so we construct the following reaction table for the stoichiometry:

| Amount (mol) | $\mathbf{H P r}(\mathbf{a q})$ | + | $\mathbf{O H}^{-}(a q)$ | $\longrightarrow$ | $\operatorname{Pr}^{-}(a q)$ | + |
| :--- | ---: | :---: | :---: | :---: | :---: | :---: |
| Initial | 0.004000 |  | 0.003000 | 0 |  | - |
| Change | -0.003000 | -0.003000 |  | +0.003000 | - |  |
| Final | 0.001000 | 0 | 0.003000 | - |  |  |

The last line of this table shows the new initial amounts of HPr and $\mathrm{Pr}^{-}$that will react to attain a new equilibrium. However, with $x$ very small, we assume that the $[\mathrm{HPr}] /\left[\mathrm{Pr}^{-}\right]$
ratio at equilibrium is essentially equal to the ratio of these new initial amounts (see Comment in Sample Problem 19.1). Thus,

$$
\frac{[\mathrm{HPr}]}{\left[\mathrm{Pr}^{-}\right]}=\frac{0.001000 \mathrm{~mol}}{0.003000 \mathrm{~mol}}=0.3333
$$

Solving for $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$:

$$
\begin{aligned}
{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] } & =K_{\mathrm{a}} \times \frac{[\mathrm{HPr}]}{\left[\mathrm{Pr}^{-}\right]}=\left(1.3 \times 10^{-5}\right)(0.3333)=4.3 \times 10^{-6} \mathrm{M} \\
\mathrm{pH} & =5.37
\end{aligned}
$$

(c) 40.00 mL of 0.1000 M NaOH added. Calculating $\left[\mathrm{Pr}^{-}\right]$after all HPr has reacted:

$$
\begin{aligned}
{\left[\operatorname{Pr}^{-}\right] } & =\frac{0.004000 \mathrm{~mol}}{0.04000 \mathrm{~L}+0.04000 \mathrm{~L}}=0.05000 \mathrm{M} \\
\text { Calculating } K_{\mathrm{b}}: \quad K_{\mathrm{b}} & =\frac{K_{\mathrm{w}}}{K_{\mathrm{a}}}=\frac{1.0 \times 10^{-14}}{1.3 \times 10^{-5}}=7.7 \times 10^{-10}
\end{aligned}
$$

Solving for $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$as described in the text:

$$
\begin{aligned}
{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] } & \approx \frac{K_{\mathrm{w}}}{\sqrt{K_{\mathrm{b}} \times\left[\mathrm{Pr}^{-}\right]}}=\frac{1.0 \times 10^{-14}}{\sqrt{\left(7.7 \times 10^{-10}\right)(0.05000)}}=1.6 \times 10^{-9} \mathrm{M} \\
\mathrm{pH} & =8.80
\end{aligned}
$$

(d) 50.00 mL of 0.1000 M NaOH added.

$$
\text { Moles of excess } \mathrm{OH}^{-}=(0.1000 \mathrm{M})(0.05000 \mathrm{~L}-0.04000 \mathrm{~L})=0.001000 \mathrm{~mol}
$$

$$
\begin{aligned}
{\left[\mathrm{OH}^{-}\right] } & =\frac{\text { moles of excess } \mathrm{OH}^{-}}{\text {total volume }}=\frac{0.001000 \mathrm{~mol}}{0.09000 \mathrm{~L}}=0.01111 \mathrm{M} \\
{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] } & =\frac{K_{\mathrm{w}}}{\left[\mathrm{OH}^{-}\right]}=\frac{1.0 \times 10^{-14}}{0.01111}=9.0 \times 10^{-13} \mathrm{M} \\
\mathrm{pH} & =12.05
\end{aligned}
$$

CHECK As expected from the continuous addition of base, the pH increases through the four stages. Be sure to round off and check the arithmetic along the way.

FOLLOW-UP PROBLEM 19.4 A chemist titrates 20.00 mL of 0.2000 M HBrO $\left(K_{\mathrm{a}}=2.3 \times 10^{-9}\right)$ with 0.1000 M NaOH . What is the $\mathrm{pH}(\mathbf{a})$ before any base is added; (b) when $[\mathrm{HBrO}]=\left[\mathrm{BrO}^{-}\right] ;(\mathbf{c})$ at the equivalence point; (d) when the moles of $\mathrm{OH}^{-}$ added are twice the moles of HBrO originally present? (e) Sketch the titration curve.

## Weak Base-Strong Acid Titration Curves

In the previous case, we titrated a weak acid with a strong base. The opposite process is the titration of a weak base $\left(\mathrm{NH}_{3}\right)$ with a strong acid $(\mathrm{HCl})$, shown in Figure 19.9. Note that the curve has the same shape as the weak acid-strong base curve (Figure 19.8, p. 845), but it is inverted. Thus, the regions of the curve have the same features, but the pH decreases throughout the process:

1. The initial solution is that of a weak base, so the pH starts out above 7.00.
2. The pH decreases gradually in the buffer region, where significant amounts of base $\left(\mathrm{NH}_{3}\right)$ and conjugate acid $\left(\mathrm{NH}_{4}{ }^{+}\right)$are present. At the midpoint of the buffer region, the pH equals the $\mathrm{p} K_{\mathrm{a}}$ of the ammonium ion.
3. After the buffer region, the curve drops vertically to the equivalence point, at which all the $\mathrm{NH}_{3}$ has reacted and the solution contains only $\mathrm{NH}_{4}^{+}$and $\mathrm{Cl}^{-}$. Note that the pH at the equivalence point is below 7.00 because $\mathrm{Cl}^{-}$does not react with water and $\mathrm{NH}_{4}^{+}$is acidic:

$$
\mathrm{NH}_{4}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{3}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)
$$

4. Beyond the equivalence point, the pH decreases slowly as excess $\mathrm{H}_{3} \mathrm{O}^{+}$is added.

Figure 19.9 Curve for a weak base-strong acid titration. Titrating 40.00 mL of $0.1000 \mathrm{M} \mathrm{NH}_{3}$ with a solution of 0.1000 M HCl leads to a curve whose shape is the same as that of the weak acid-strong base curve in Figure 19.8 but inverted. The midpoint of the buffer region oc-
curs when $\left[\mathrm{NH}_{3}\right]=\left[\mathrm{NH}_{4}^{+}\right]$; the pH at this point equals the $\mathrm{p} K_{\mathrm{a}}$ of the acid, $\mathrm{NH}_{4}{ }^{+}$. In this case, methyl red (photo) is a suitable indicator because it changes color on the steep portion. The blow-up circles depict the relative numbers of species present at key points during the titration.

For this titration also, we must be more careful in choosing the indicator than we would be for a strong acid-strong base titration. Phenolphthalein changes color too soon and too slowly to indicate the equivalence point; but methyl red lies on the steep portion of the curve and straddles the equivalence point, so it is a perfect choice.

## Titration Curves for Polyprotic Acids

As we discussed in Section 18.4, polyprotic acids have more than one ionizable proton. Except for sulfuric acid, the common polyprotic acids are all weak. The successive $K_{\mathrm{a}}$ values for a polyprotic acid differ by several orders of magnitude, which means that the first $\mathrm{H}^{+}$is lost much more easily than subsequent ones, as these values for sulfurous acid show:

$$
\begin{gathered}
\mathrm{H}_{2} \mathrm{SO}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HSO}_{3}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \\
K_{\mathrm{a} 1}=1.4 \times 10^{-2} \quad \text { and } \quad \mathrm{p} K_{\mathrm{a} 1}=1.85 \\
\mathrm{HSO}_{3}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{SO}_{3}{ }^{2-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \\
K_{\mathrm{a} 2}=6.5 \times 10^{-8} \quad \text { and } \quad \mathrm{p} K_{\mathrm{a} 2}=7.19
\end{gathered}
$$

In a titration of a diprotic acid such as $\mathrm{H}_{2} \mathrm{SO}_{3}$, two $\mathrm{OH}^{-}$ions are required to completely remove both $\mathrm{H}^{+}$ions from each molecule of acid. Figure 19.10 shows the titration curve for sulfurous acid with strong base. Because of the large difference in $K_{\mathrm{a}}$ values, we assume that each mole of $\mathrm{H}^{+}$is titrated separately; that is, all $\mathrm{H}_{2} \mathrm{SO}_{3}$ molecules lose one $\mathrm{H}^{+}$before any $\mathrm{HSO}_{3}{ }^{-}$ions lose one:

$$
\mathrm{H}_{2} \mathrm{SO}_{3} \xrightarrow{1 \mathrm{~mol} \mathrm{OH}^{-}} \mathrm{HSO}_{3}^{-} \xrightarrow{1 \mathrm{~mol} \mathrm{OH}^{-}} \mathrm{SO}_{3}{ }^{2-}
$$

As you can see from the curve in Figure 19.10, the loss of each mole of $\mathrm{H}^{+}$ shows up as a separate equivalence point and buffer region. As on the curve for a weak monoprotic acid (Figure 19.8, p. 845), the pH at the midpoint of the buffer region is equal to the $\mathrm{p} K_{\mathrm{a}}$ of that acidic species. Note also that the same volume of added base (in this case, 40.00 mL of $0.1000 \mathrm{M} \mathrm{OH}^{-}$) is required to remove each mole of $\mathrm{H}^{+}$.

## Amino Acids as Biological Polyprotic Acids

Amino acids, the molecules that link together to form proteins (Sections 13.2 and 15.6), have the general formula $\mathrm{NH}_{2}-\mathrm{CH}(\mathrm{R})-\mathrm{COOH}$, where R can be one of about 20 different groups. At low pH , both the amino group $\left(-\mathrm{NH}_{2}\right)$ and the acid group $(-\mathrm{COOH})$ are protonated: ${ }^{+} \mathrm{NH}_{3}-\mathrm{CH}(\mathrm{R})-\mathrm{COOH}$. Thus, in this form the amino acid behaves like a polyprotic acid. In the case of glycine $(\mathrm{R}=$ H ), the simplest amino acid, the dissociation reactions and $\mathrm{p} K_{\mathrm{a}}$ values are

$$
\begin{aligned}
& { }^{+} \mathrm{NH}_{3} \mathrm{CH}_{2} \mathrm{COOH}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons{ }^{+} \mathrm{NH}_{3} \mathrm{CH}_{2} \mathrm{COO}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \\
& \mathrm{p} K_{\mathrm{a} 1}=2.35 \\
& { }^{+} \mathrm{NH}_{3} \mathrm{CH}_{2} \mathrm{COO}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{COO}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q)
\end{aligned} \mathrm{p} K_{\mathrm{a} 2}=9.78
$$

The $\mathrm{p} K_{\mathrm{a}}$ values show that the -COOH group is much more acidic than the $-\mathrm{NH}_{3}{ }^{+}$group. As we saw with $\mathrm{H}_{2} \mathrm{SO}_{3}$, the protons are titrated separately, so virtually all the -COOH protons are removed before any $-\mathrm{NH}_{3}{ }^{+}$protons are:

Thus, at physiological $\mathrm{pH}(\sim 7)$, glycine exists predominantly as a zwitterion (German zwitter, "double"), a species with opposite charges on the same molecule: ${ }^{+} \mathrm{NH}_{3} \mathrm{CH}_{2} \mathrm{COO}^{-}$. Among the 20 different R groups of amino acids in proteins, several have additional $-\mathrm{COO}^{-}$or $-\mathrm{NH}_{3}{ }^{+}$groups at pH 7 (see Figure 15.28, p. 667).

When amino acids link to form a protein, their charged R groups give the protein its overall charge and often play a role in its function. A widely studied example of the effect of charge on function occurs in the hereditary disease sickle cell anemia. Normal red blood cells are packed tightly with molecules of hemoglobin. Two of the amino acids in this protein-both glutamic acid-are critical to the mobility of hemoglobin molecules, and this mobility is critical to the shape of the red blood cells (Figure 19.11). Each glutamic acid has a negatively charged R group ( $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{COO}^{-}$). The abnormal hemoglobin molecules in sickle cell anemia have uncharged $\left(-\mathrm{CH}_{3}\right)$ groups instead of these charged ones. This change in just two of hemoglobin's 574 amino acids lowers the charge repulsions between hemoglobin molecules. As a result, they clump together in fiber-like structures, which leads to the sickle shape of the red blood cells. The misshapen cells block capillaries, and the painful course of sickle cell anemia usually ends in early death.

## Section Summary

An acid-base $(\mathrm{pH})$ indicator is a weak acid that has differently colored acidic and basic forms and changes color over about 2 pH units. - In a strong acid-strong base titration, the pH starts out low, rises slowly, then shoots up near the equivalence point $(\mathrm{pH}=7)$. - In a weak acid-strong base titration, the pH starts out higher than in the strong acid titration, rises slowly in the buffer region ( $\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}$ at the midpoint), then rises more quickly near the equivalence point ( $\mathrm{pH}>7$ ) -A weak base-strong acid titration has a shape that is the inverserfthe weak acid-strong base ease, with the pH decreasing to the equivalence point $(\mathrm{pH}<7)$. • Polyprotic acids have two or more acidic protons, each with its own $K_{\mathrm{a}}$ value. Because the $K_{\mathrm{a}}$ 's differ by several orders of magnitude, each proton is titrated separately. - Amino acids exist in different charged forms that depend on the pH of the solution.

### 19.3 EQUILIBRIA OF SLIGHTLY SOLUBLE IONIC COMPOUNDS

In this section, we explore the aqueous equilibria of slightly soluble ionic compounds, which up to now we've called "insoluble." In Chapter 13, we found that most solutes, even those called "soluble," have a limited solubility in a particular solvent. Add more than this amount, and some solute remains undissolved. In a saturated solution at a particular temperature, equilibrium exists between the undissolved and dissolved solute. Slightly soluble ionic compounds have a relatively low solubility, so they reach equilibrium with relatively little solute dissolved. At this point, it would be a good idea for you to review the solubility rules listed in Table 4.1 (p. 148).

When a soluble ionic compound dissolves in water, it dissociates completely into ions. In this discussion, we will assume that the small amount of a slightly soluble ionic compound that does dissolve in water also dissociates completely into ions. In reality, however, this is not the case. Many slightly soluble salts, particularly those of transition metals and heavy main-group metals, have metalnonmetal bonds with significant covalent character, and their solutions often contain other species that are partially dissociated or even undissociated. For example, when lead(II) chloride is thoroughly stirred in water (see photo), a small amount dissolves, and the solution contains not only the $\mathrm{Pb}^{2+}(a q)$ and $\mathrm{Cl}^{-}(a q)$ ions expected from complete dissociation, but also undissociated $\mathrm{PbCl}_{2}(a q)$

Figure 19.11 Sickle shape of red blood cells in sickle cell anemia.

$\mathrm{PbCl}_{2}$, a slightly soluble ionic compound.
molecules and $\mathrm{PbCl}^{+}(a q)$ ions. In solutions of some other salts, such as $\mathrm{CaSO}_{4}$, there are no molecules, but pairs of ions exist, such as $\mathrm{Ca}^{2+} \mathrm{SO}_{4}{ }^{2-}(a q)$. These species increase the solubility above what we calculate assuming complete dissociation. More advanced courses address these complexities, but we will only hint at some of them in the Comments of several sample problems. For these reasons, it is best to treat our calculations here as first approximations.

## The Ion-Product Expression ( $Q_{\mathrm{sp}}$ ) and the Solubility-Product Constant ( $K_{\text {sp }}$ )

If we make the assumption that there is complete dissociation of a slightly soluble ionic compound into its component ions, then equilibrium exists between solid solute and aqueous ions. Thus, for example, for a saturated solution of lead(II) sulfate in water, we have

$$
\mathrm{PbSO}_{4}(s) \rightleftharpoons \mathrm{Pb}^{2+}(a q)+\mathrm{SO}_{4}^{2-}(a q)
$$

As with all the other equilibrium systems we've looked at, this one can be expressed by a reaction quotient:

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{Pb}^{2+}\right]\left[\mathrm{SO}_{4}^{2-}\right]}{\left[\mathrm{PbSO}_{4}\right]}
$$

As in previous cases, we incorporate the constant concentration of the solid, $\left[\mathrm{PbSO}_{4}\right]$, into the value of $Q_{\mathrm{c}}$, which gives the ion-product expression, $Q_{\mathrm{sp}}$ :

$$
\begin{aligned}
Q_{\mathrm{sp}} & =Q_{\mathrm{c}}\left[\mathrm{PbSO}_{4}\right] \\
& =\left[\mathrm{Pb}^{2+}\right]\left[\mathrm{SO}_{4}{ }^{2-}\right]
\end{aligned}
$$

And, when solid $\mathrm{PbSO}_{4}$ attains equilibrium with $\mathrm{Pb}^{2+}$ and $\mathrm{SO}_{4}{ }^{2-}$ ions, that is, when the solution reaehes saturation the numerical value of $Q_{\text {sp }}$ attains a constant value called the solubility-product constant, $\boldsymbol{K}_{\text {sp }}$. The $K_{\text {sp }}$ for $\mathrm{PbSO}_{4}$ at $25^{\circ} \mathrm{C}$, for example, is $1.6 \times 10^{-8}$.

As we've seen with other equilibrium constants, a given $K_{\text {sp }}$ value depends only on the temperature, not on the individual ion concentrations. Suppose, for example, you add some lead(II) nitrate, a soluble lead salt, to increase the solution's $\left[\mathrm{Pb}^{2+}\right]$. The equilibrium position shifts to the left, and $\left[\mathrm{SO}_{4}{ }^{2-}\right]$ goes down as more $\mathrm{PbSO}_{4}$ precipitates; so the $K_{\text {sp }}$ value is maintained.

The form of $Q_{\mathrm{sp}}$ is identical to that of the other reaction quotients we have written: each ion concentration is raised to an exponent equal to the coefficient in the balanced equation, which in this case also equals the subscript of each ion in the compound's formula. Thus, in general, for a saturated solution of a slightly soluble ionic compound, $\mathrm{M}_{p} \mathrm{X}_{q}$, composed of the ions $\mathrm{M}^{n+}$ and $\mathrm{X}^{z^{-}}$, the equilibrium condition is

$$
\begin{equation*}
Q_{\mathrm{sp}}=\left[\mathrm{M}^{n+}\right]^{p}\left[\mathrm{X}^{z-}\right]^{q}=K_{\mathrm{sp}} \tag{19.2}
\end{equation*}
$$

At saturation, the concentration terms have their equilibrium values, so we can write the ion-product expression directly with the symbol $K_{\text {sp }}$. For example, the equation and ion-product expression that describe a saturated solution of $\mathrm{Cu}(\mathrm{OH})_{2}$ are

$$
\begin{aligned}
\mathrm{Cu}(\mathrm{OH})_{2}(s) & \rightleftharpoons \mathrm{Cu}^{2+}(a q)+2 \mathrm{OH}^{-}(a q) \\
K_{\mathrm{sp}} & =\left[\mathrm{Cu}^{2+}\right]\left[\mathrm{OH}^{-}\right]^{2}
\end{aligned}
$$

Insoluble metal sulfides present a slightly different case. The sulfide ion, $\mathrm{S}^{2-}$, is so basic that it is not stable in water and reacts completely to form the hydrogen sulfide ion $\left(\mathrm{HS}^{-}\right)$and the hydroxide ion $\left(\mathrm{OH}^{-}\right)$:

$$
\mathrm{S}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{HS}^{-}(a q)+\mathrm{OH}^{-}(a q)
$$

For instance, when manganese(II) sulfide is shaken with water, the solution contains $\mathrm{Mn}^{2+}, \mathrm{HS}^{-}$, and $\mathrm{OH}^{-}$ions. Although the sulfide ion does not exist as such
in water, you can imagine the dissolution process as the sum of two steps, with $\mathrm{S}^{2-}$ occurring as an intermediate that is consumed immediately:

$$
\begin{aligned}
& \mathrm{MnS}(s) \rightleftharpoons \mathrm{Mn}^{2+}(a q)+\mathrm{S}^{2-}(a q) \\
& \frac{\mathrm{S}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)}{\mathrm{MnS}(s)+\mathrm{HS}_{2}(a q)+\mathrm{OH}^{-}(a q)} \rightleftharpoons \mathrm{Mn}^{2+}(a q)+\mathrm{HS}^{-}(a q)+\mathrm{OH}^{-}(a q)
\end{aligned}
$$

Therefore, the ion-product expression is

$$
K_{\mathrm{sp}}=\left[\mathrm{Mn}^{2+}\right]\left[\mathrm{HS}^{-}\right]\left[\mathrm{OH}^{-}\right]
$$

## SAMPLE PROBLEM 19.5 Writing Ion-Product Expressions for Slightly

 Soluble Ionic CompoundsPROBLEM Write the ion-product expression for each compound: (a) magnesium carbonate; (b) iron(II) hydroxide; (c) calcium phosphate; (d) silver sulfide.
PLAN We write an equation that describes a saturated solution and then write the ionproduct expression, $K_{\mathrm{sp}}$, according to Equation 19.2, noting the sulfide in part (d).
SOLUTION (a) Magnesium carbonate:

$$
\mathrm{MgCO}_{3}(s) \rightleftharpoons \mathrm{Mg}^{2+}(a q)+\mathrm{CO}_{3}^{2-}(a q) \quad K_{\mathrm{sp}}=\left[\mathrm{Mg}^{2+}\right]\left[\mathrm{CO}_{3}^{2-}\right]
$$

(b) Iron(II) hydroxide:

$$
\mathrm{Fe}(\mathrm{OH})_{2}(s) \rightleftharpoons \mathrm{Fe}^{2+}(a q)+2 \mathrm{OH}^{-}(a q) \quad K_{\mathrm{sp}}=\left[\mathrm{Fe}^{2+}\right]\left[\mathrm{OH}^{-}\right]^{2}
$$

(c) Calcium phosphate:

$$
\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s) \rightleftharpoons 3 \mathrm{Ca}^{2+}(a q)+2 \mathrm{PO}_{4}^{3-}(a q) \quad K_{\mathrm{sp}}=\left[\mathrm{Ca}^{2+}\right]^{3}\left[\mathrm{PO}_{4}^{3-}\right]^{2}
$$

(d) Silver sulfide:

$$
\left.\begin{array}{rl}
\mathrm{Ag}_{2} \mathrm{~S}(s) & \rightleftharpoons 2 \mathrm{Ag}^{+}(a q)+\mathrm{S}^{2-}(a q) \\
\frac{\mathrm{S}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)}{\mathrm{Ag}_{2} \mathrm{~S}(s)+\mathrm{H}_{2} \mathrm{O}(l)} \rightleftharpoons \mathrm{HS}^{-}(a q)+\mathrm{OH}^{-}(a q) & 2 \mathrm{Ag}^{+}(a q)+\mathrm{HS}^{-}(a q)+\mathrm{OH}^{-}(a q)
\end{array} K_{\mathrm{sp}}=\left[\mathrm{Ag}^{+}\right]^{2}\left[\mathrm{HS}^{-}\right]\left[\mathrm{OH}^{-}\right]\right] .
$$

CHECK Except for part (d), you can check by reversing the process to see if you obtain the formula of the compound from $K_{\text {sp }}$.
COMMENT In part (d), we include $\mathrm{H}_{2} \mathrm{O}$ as reactant to obtain a balanced equation.
FOLLOW-UP PROBLEM 19.5 Write the ion-product expression for each compound: (a) calcium sulfate; (b) chromium(III) carbonate; (c) magnesium hydroxide; (d) arsenic(III) sulfide.

The value of $K_{\mathrm{sp}}$ indicates how far to the right the dissolution proceeds at equilibrium (saturation). Table 19.2 presents some representative $K_{\text {sp }}$ values. (Appendix C includes a much more extensive list.) Even though the values are all quite low, they range over many orders of magnitude.

## Calculations Involving the Solubility-Product Constant

In Chapters 17 and 18, we described two types of equilibrium problems. In one type, we use concentrations to find $K$, and in the other, we use $K$ to find concentrations. Here we encounter the same two types.
Determining $K_{\text {sp }}$ from Solubility The solubilities of ionic compounds are determined experimentally, and several chemical handbooks tabulate them. Most solubility values are given in units of grams of solute dissolved in 100. grams of $\mathrm{H}_{2} \mathrm{O}$. Because the mass of compound in solution is small, a negligible error is introduced if we assume that " 100 g of water" is equal to " 100 mL of solution." We then convert the solubility from grams of solute per $100 . \mathrm{mL}$ of solution to molar solubility, the amount (mol) of solute dissolved per liter of solution (that is, the molarity of the solute). Next, we use the equation for the dissolution of the solute to find the molarity of each ion and substitute into the ion-product expression to find the value of $K_{\mathrm{sp}}$.

Table 19.2 Solubility-Product Constants ( $K_{\text {sp }}$ ) of Selected lonic Compounds at $25^{\circ} \mathrm{C}$

| Name, Formula | $K_{\text {sp }}$ |
| :---: | :---: |
| Aluminum hydroxide, $\mathrm{Al}(\mathrm{OH})_{3}$ | $3 \times 10^{-34}$ |
| Cobalt(II) carbonate, $\mathrm{CoCO}_{3}$ | $1.0 \times 10^{-10}$ |
| Iron(II) hydroxide, $\mathrm{Fe}(\mathrm{OH})_{2}$ | $4.1 \times 10^{-15}$ |
| Lead(II) fluoride, $\mathrm{PbF}_{2}$ | $3.6 \times 10^{-8}$ |
| Lead(II) sulfate, $\mathrm{PbSO}_{4}$ | $1.6 \times 10^{-8}$ |
| Mercury(I) iodide, $\mathrm{Hg}_{2} \mathrm{I}_{2}$ | $4.7 \times 10^{-29}$ |
| Silver sulfide, $\mathrm{Ag}_{2} \mathrm{~S}$ | $8 \times 10^{-48}$ |
| Zinc iodate, $\mathrm{Zn}\left(\mathrm{IO}_{3}\right)_{2}$ | $3.9 \times 10^{-6}$ |

## SAMPLE PROBLEM 19.6 Determining $K_{\text {sp }}$ from Solubility

PROBLEM (a) Lead(II) sulfate $\left(\mathrm{PbSO}_{4}\right)$ is a key component in lead-acid car batteries. Its solubility in water at $25^{\circ} \mathrm{C}$ is $4.25 \times 10^{-3} \mathrm{~g} / 100 \mathrm{~mL}$ solution. What is the $K_{\text {sp }}$ of $\mathrm{PbSO}_{4}$ ? (b) When lead(II) fluoride $\left(\mathrm{PbF}_{2}\right)$ is shaken with pure water at $25^{\circ} \mathrm{C}$, the solubility is found to be $0.64 \mathrm{~g} / \mathrm{L}$. Calculate the $K_{\mathrm{sp}}$ of $\mathrm{PbF}_{2}$.
PLAN We are given the solubilities in various units and must find $K_{\mathrm{sp}}$. For each compound, we write an equation for its dissolution to see the number of moles of each ion, and then write the ion-product expression. We convert the solubility to molar solubility, find the molarity of each ion, and substitute into the ion-product expression to calculate $K_{\text {sp }}$.
SOLUTION (a) For $\mathrm{PbSO}_{4}$. Writing the equation and ion-product ( $K_{\mathrm{sp}}$ ) expression:

$$
\mathrm{PbSO}_{4}(s) \rightleftharpoons \mathrm{Pb}^{2+}(a q)+\mathrm{SO}_{4}{ }^{2-}(a q) \quad K_{\mathrm{sp}}=\left[\mathrm{Pb}^{2+}\right]\left[\mathrm{SO}_{4}^{2-}\right]
$$

Converting solubility to molar solubility:

$$
\begin{aligned}
\text { Molar solubility of } \mathrm{PbSO}_{4} & =\frac{0.00425 \mathrm{~g} \mathrm{PbSO}_{4}}{100 \mathrm{~mL} \text { soln }} \times \frac{1000 \mathrm{~mL}}{1 \mathrm{~L}} \times \frac{1 \mathrm{~mol} \mathrm{PbSO}_{4}}{303.3 \mathrm{~g} \mathrm{PbSO}_{4}} \\
& =1.40 \times 10^{-4} M \mathrm{PbSO}_{4}
\end{aligned}
$$

Determining molarities of the ions: Because 1 mol of $\mathrm{Pb}^{2+}$ and 1 mol of $\mathrm{SO}_{4}{ }^{2-}$ form when 1 mol of $\mathrm{PbSO}_{4}$ dissolves, $\left[\mathrm{Pb}^{2+}\right]=\left[\mathrm{SO}_{4}{ }^{2-}\right]=1.40 \times 10^{-4} \mathrm{M}$.
Calculating $K_{\text {sp }}$ :

$$
K_{\mathrm{sp}}=\left[\mathrm{Pb}^{2+}\right]\left[\mathrm{SO}_{4}^{2-}\right]=\left(1.40 \times 10^{-4}\right)^{2}=1.96 \times 10^{-8}
$$

(b) For $\mathrm{PbF}_{2}$. Writing the equation and $K_{\text {sp }}$ expression:

$$
\mathrm{PbF}_{2}(s) \rightleftharpoons \mathrm{Pb}^{2+}(a q)+2 \mathrm{~F}^{-}(a q) \quad K_{\mathrm{sp}}=\left[\mathrm{Pb}^{2+}\right]\left[\mathrm{F}^{-}\right]^{2}
$$

Converting solubility to molar solubility:

$$
\text { Molar solubility of } \mathrm{PbF}_{2}=\frac{0.64 \mathrm{~g} \mathrm{PbF}_{2}}{1 \mathrm{~L} \text { soln }} \times \frac{1 \mathrm{~mol} \mathrm{PbF}_{2}}{245.2 \mathrm{~g} \mathrm{PbF}_{2}}=2.6 \times 10^{-3} M \mathrm{PbF}_{2}
$$

Determining molarities of the ions: Since 1 mol of $\mathrm{Pb}^{2+}$ and 2 mol of $\mathrm{F}^{-}$form when 1 mol of $\mathrm{PbF}_{2}$ dissolves,

$$
\left[\mathrm{Pb}^{2+}\right]=2.6 \times 10^{-3} M \quad \text { and } \quad\left[\mathrm{F}^{-}\right]=2\left(2.6 \times 10^{-3} M\right)=5.2 \times 10^{-3} M
$$

Calculating $K_{\mathrm{sp}}$ :

$$
K_{\mathrm{sp}}=\left[\mathrm{Pb}^{2+}\right]\left[\mathrm{F}^{-}\right]^{2}=\left(2.6 \times 10^{-3}\right)\left(5.2 \times 10^{-3}\right)^{2}=7.0 \times 10^{-8}
$$

CHECK The low solubilities are consistent with $K_{\text {sp }}$ values being small. (a) The molar solubility seems about right: $\sim \frac{4 \times 10^{-2} \mathrm{~g} / \mathrm{L}}{3 \times 10^{2} \mathrm{~g} / \mathrm{mol}} \approx 1.3 \times 10^{-4} M$. Squaring this number gives $1.7 \times 10^{-8}$, close to the calculated $K_{\text {sp }}$. (b) We check the final step as follows: $\sim\left(3 \times 10^{-3}\right)\left(5 \times 10^{-3}\right)^{2}=7.5 \times 10^{-8}$, close to the calculated $K_{\text {sp }}$.
COMMENT 1. In part (b), the formula $\mathrm{PbF}_{2}$ means that $\left[\mathrm{F}^{-}\right]$is twice $\left[\mathrm{Pb}^{2+}\right]$. Then we square this value of $\left[\mathrm{F}^{-}\right]$. Always follow the ion-product expression explicitly.
2. The tabulated $K_{\text {sp }}$ values for these compounds (Table 19.2) are lower than our calculated values. For $\mathrm{PbF}_{2}$, for instance, the tabulated value is $3.6 \times 10^{-8}$, but we calculated $7.0 \times 10^{-8}$ from solubility data. The discrepancy arises because we assumed that the $\mathrm{PbF}_{2}$ in solution dissociates completely to $\mathrm{Pb}^{2+}$ and $\mathrm{F}^{-}$. Here is an example of the complexity pointed out at the beginning of this section. Actually, about a third of the $\mathrm{PbF}_{2}$ dissolves as $\mathrm{PbF}^{+}(a q)$ and a small amount as undissociated $\mathrm{PbF}_{2}(a q)$. The solubility $(0.64 \mathrm{~g} / \mathrm{L})$ is determined experimentally and includes these other species, which we did not include in our simple calculation. This is why we treat such calculated $K_{\text {sp }}$ values as approximations. FOLLOW-UP PROBLEM 19.6 When powdered fluorite ( $\mathrm{CaF}_{2}$; see photo) is shaken with pure water at $18^{\circ} \mathrm{C}, 1.5 \times 10^{-4} \mathrm{~g}$ dissolves for every 10.0 mL of solution. Calculate the $K_{\text {sp }}$ of $\mathrm{CaF}_{2}$ at $18^{\circ} \mathrm{C}$.

Determining Solubility from $\boldsymbol{K}_{\mathbf{s p}}$ The reverse of Sample Problem 19.6 involves finding the solubility of a compound based on its formula and $K_{\text {sp }}$ value. An approach similar to the one we used for weak acids in Sample Problem 18.8 is to define the unknown amount dissolved-molar solubility-as $S$. Then we define the ion concentrations in terms of this unknown in a reaction table, and solve for $S$.

## SAMPLE PROBLEM 19.7 Determining Solubility from $K_{\text {sp }}$

PROBLEM Calcium hydroxide (slaked lime) is a major component of mortar, plaster, and cement, and solutions of $\mathrm{Ca}(\mathrm{OH})_{2}$ are used in industry as a cheap, strong base. Calculate the solubility of $\mathrm{Ca}(\mathrm{OH})_{2}$ in water if the $K_{\text {sp }}$ is $6.5 \times 10^{-6}$.
PLAN We write the dissolution equation and the ion-product expression. We know $K_{\text {sp }}$ $\left(6.5 \times 10^{-6}\right)$; to find molar solubility $(S)$, we set up a reaction table that expresses $\left[\mathrm{Ca}^{2+}\right]$ and $\left[\mathrm{OH}^{-}\right]$in terms of $S$, substitute into the ion-product expression, and solve for $S$.
SOLUTION Writing the equation and ion-product expression:

$$
\mathrm{Ca}(\mathrm{OH})_{2}(s) \rightleftharpoons \mathrm{Ca}^{2+}(a q)+2 \mathrm{OH}^{-}(a q) \quad K_{\mathrm{sp}}=\left[\mathrm{Ca}^{2+}\right]\left[\mathrm{OH}^{-}\right]^{2}=6.5 \times 10^{-6}
$$

Setting up a reaction table, with $S=$ molar solubility:

| Concentration $(M)$ | $\mathbf{C a}(\mathbf{O H})_{2}(s)$ | $\rightleftharpoons$ | $\mathbf{C a}^{2+}(a q)$ | + |
| :--- | :---: | :---: | :---: | :---: |
| Initial | - |  | 0 | $\mathbf{2 O H}^{-}(\mathbf{a q})$ |
| Change | - | $+S$ | 0 |  |
| Equilibrium | - |  | $S$ | $+2 S$ |

Substituting into the ion-product expression and solving for $S$ :

$$
\begin{aligned}
K_{\mathrm{sp}} & =\left[\mathrm{Ca}^{2+}\right]\left[\mathrm{OH}^{-}\right]^{2}=(S)(2 S)^{2}=(S)\left(4 S^{2}\right)=4 S^{3}=6.5 \times 10^{-6} \\
S & =\sqrt[3]{\frac{6.5 \times 10^{-6}}{4}}=1.2 \times 10^{-2} M
\end{aligned}
$$

CHECK We expect a low solubility from a slightly soluble salt. If we reverse the calculation, we should obtain the given $K_{\text {sp }}: 4\left(1.2 \times 10^{-2}\right)^{3}=6.9 \times 10^{-6}$, close to $6.5 \times 10^{-6}$.
COMMENT 1. Note that we did not double and then square $\left[\mathrm{OH}^{-}\right] .2 S$ is the $\left[\mathrm{OH}^{-}\right]$, so we just squared it, as the ion-product expression required.
2. Once again, we assumed that the solid dissociates completely. Actually, the solubility is increased to about $2.0 \times 10^{-2} M$ by the presence of $\mathrm{CaOH}^{+}(\mathrm{aq})$ formed in the reaction $\mathrm{Ca}(\mathrm{OH})_{2}(s) \rightleftharpoons \mathrm{CaOH}^{+}(a q)+\mathrm{OH}^{-}(a q)$. Our calculated answer is only approximate because we did not take this other species into account.
FOLLOW-UP PROBLEM 19.7 A suspension of $\mathrm{Mg}(\mathrm{OH})_{2}$ in water is marketed as "milk of magnesia," which alleviates minor symptoms of indigestion by neutralizing stomach acid. The $\left[\mathrm{OH}^{-}\right]$is too low to harm the mouth and throat, but the suspension dissolves in the acidic stomach juices. What is the molar solubility of $\operatorname{Mg}(\mathrm{OH})_{2}$ ( $K_{\text {sp }}=6.3 \times 10^{-10}$ ) in pure water?

Using $K_{\text {sp }}$ Values to Compare Solubilities The $K_{\text {sp }}$ values provide a guide to relative solubility, as long as we compare compounds whose formulas contain the same total number of ions. In such cases, the higher the $K_{\mathrm{sp}}$, the greater the solubility. Table 19.3 shows this point for several compounds. Note that for compounds that form three ions, the relationship holds whether the cation/anion ratio is $1 / 2$ or $2 / 1$, because the mathematical expression containing $S$ is the same $\left(4 S^{3}\right)$ in the calculation (see Sample Problem 19.7).

| Table 19.3 | Relationship Between $\boldsymbol{K}_{\text {sp }}$ and Solubility at $\mathbf{2 5}{ }^{\circ} \mathbf{C}$ <br> No. of lons | Formula | Cation/Anion | $\boldsymbol{K}_{\text {sp }}$ |
| :---: | :--- | :--- | :---: | :---: |

Figure 19.12 The effect of a common ion on solubility. When a common ion is added to a saturated solution of an ionic compound, the solubility is lowered and more of the compound precipitates. A, Lead(II) chromate, a slightly soluble salt, forms a saturated aqueous solution. $\mathbf{B}$, When $\mathrm{Na}_{2} \mathrm{CrO}_{4}$ solution is added, the amount of $\mathrm{PbCrO}_{4}(\mathrm{~s})$ increases. Thus, $\mathrm{PbCrO}_{4}$ is less soluble in the presence of the common ion $\mathrm{CrO}_{4}{ }^{2-}$.

## The Effect of a Common Ion on Solubility

The presence of a common ion decreases the solubility of a slightly soluble ionic compound. As in acid-base systems, Le Châtelier's principle helps explain this effect. Let's examine the equilibrium condition for a saturated solution of lead(II) chromate:

$$
\mathrm{PbCrO}_{4}(s) \rightleftharpoons \mathrm{Pb}^{2+}(a q)+\mathrm{CrO}_{4}^{2-}(a q) \quad K_{\mathrm{sp}}=\left[\mathrm{Pb}^{2+}\right]\left[\mathrm{CrO}_{4}^{2-}\right]=2.3 \times 10^{-13}
$$

At a given temperature, $K_{\mathrm{sp}}$ depends on the product of the ion concentrations. If the concentration of either ion goes up, the other must go down to maintain $K_{\text {sp }}$. Suppose we add $\mathrm{Na}_{2} \mathrm{CrO}_{4}$, a soluble salt, to the saturated $\mathrm{PbCrO}_{4}$ solution. The concentration of the common ion, $\mathrm{CrO}_{4}{ }^{2-}$, increases, and some of it combines with $\mathrm{Pb}^{2+}$ ion to form more solid $\mathrm{PbCrO}_{4}$ (Figure 19.12). The overall effect is a shift in the position of equilibrium to the left:

$$
\mathrm{PbCrO}_{4}(s) \rightleftharpoons \mathrm{Pb}^{2+}(a q)+\mathrm{CrO}_{4}^{2-}(a q ; \text { added })
$$

After the addition, $\left[\mathrm{CrO}_{4}{ }^{2-}\right]$ is higher, but $\left[\mathrm{Pb}^{2+}\right]$ is lower. In this case, $\left[\mathrm{Pb}^{2+}\right]$ represents the amount of $\mathrm{PbCrO}_{4}$ dissolved; thus, in effect, the solubility of $\mathrm{PbCrO}_{4}$ has decreased. The same result is obtained if we dissolve $\mathrm{PbCrO}_{4}$ in a $\mathrm{Na}_{2} \mathrm{CrO}_{4}$ solution. We also obtain this result by adding a soluble lead(II) salt, such as $\mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}$. The added $\mathrm{Pb}^{2+}$ ion combines with some $\mathrm{CrO}_{4}{ }^{2-}(\mathrm{aq})$, thereby lowering the amount of dissolved $\mathrm{PbCrO}_{4}$.

## SAMPLE PROBLEM 19.8 Calculating the Effect of a Common Ion

 on SolubilityPROBLEM In Sample Problem 19.7, we calculated the solubility of $\mathrm{Ca}(\mathrm{OH})_{2}$ in water. What is its solubility in $0.10 \mathrm{M} \mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}$ ? $K_{\text {sp }}$ of $\mathrm{Ca}(\mathrm{OH})_{2}$ is $6.5 \times 10^{-6}$.
PLAN Addition of $\mathrm{Ca}^{2+}$, the common ion, should lower the solubility. We write the equation and ion-product expression and set up a reaction table, with $\left[\mathrm{Ca}^{2+}\right]_{\text {init }}$ coming from $\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}$ and $S$ equal to $\left[\mathrm{Ca}^{2+}\right]_{\text {from } \mathrm{Ca}(\mathrm{OH})_{2} \text {. To simplify the math, we assume that, because }}$ $K_{\text {sp }}$ is low, $S$ is so small relative to $\left[\mathrm{Ca}^{2+}\right]_{\text {init }}$ that it can be neglected. Then we solve for $S$ and check the assumption.
SOLUTION Writing the equation and ion-product expression:

$$
\mathrm{Ca}(\mathrm{OH})_{2}(s) \rightleftharpoons \mathrm{Ca}^{2+}(a q)+2 \mathrm{OH}^{-}(a q) \quad K_{\mathrm{sp}}=\left[\mathrm{Ca}^{2+}\right]\left[\mathrm{OH}^{-}\right]^{2}=6.5 \times 10^{-6}
$$

Setting up the reaction table, with $S=\left[\mathrm{Ca}^{2+}\right]_{\text {from } \mathrm{Ca}(\mathrm{OH})_{2}}$ :

| Concentration $(M)$ | $\mathbf{C a}(\mathbf{O H})_{2}(\mathbf{s})$ | $\rightleftharpoons$ | $\mathrm{Ca}^{2+}(a \mathbf{q})$ | + | $\mathbf{2 O H}^{-}(a \mathbf{q})$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Initial | - |  | 0.10 | 0 |  |
| Change | - | $+S$ | $+2 S$ |  |  |
| Equilibrium | - |  | $0.10+S$ | $2 S$ |  |

Making the assumption: $K_{\text {sp }}$ is small, so $S \ll 0.10 M$; thus, $0.10 M+S \approx 0.10 M$. Substituting into the ion-product expression and solving for $S$ :

$$
K_{\mathrm{sp}}=\left[\mathrm{Ca}^{2+}\right]\left[\mathrm{OH}^{-}\right]^{2}=6.5 \times 10^{-6} \approx(0.10)(2 S)^{2}
$$

$$
\begin{aligned}
& \text { Therefore, } \quad 4 S^{2} \approx \frac{6.5 \times 10^{-6}}{0.10} \quad \text { so } \quad S \approx \sqrt{\frac{6.5 \times 10^{-5}}{4}}=4.0 \times 10^{-3} M \\
& \text { Checking the assumption: } \quad \frac{4.0 \times 10^{-3} M}{0.10 \mathrm{M}} \times 100=4.0 \%<5 \%
\end{aligned}
$$

CHECK In Sample Problem 19.7, the solubility of $\mathrm{Ca}(\mathrm{OH})_{2}$ was 0.012 M ; here it is 0.0040 M , so the solubility decreased in the presence of added $\mathrm{Ca}^{2+}$, the common ion, as expected.

FOLLOW-UP PROBLEM 19.8 To improve the quality of $x$-ray images used in the diagnosis of intestinal disorders, the patient drinks an aqueous suspension of $\mathrm{BaSO}_{4}$ before the x -ray procedure (see photo). The $\mathrm{Ba}^{2+}$ in the suspension is opaque to x -rays, but it is also toxic; thus, the $\mathrm{Ba}^{2+}$ concentration is lowered by the addition of dilute $\mathrm{Na}_{2} \mathrm{SO}_{4}$. What is the solubility of $\mathrm{BaSO}_{4}\left(K_{\text {sp }}=1.1 \times 10^{-10}\right)$ in (a) pure water and in (b) $0.10 \mathrm{Ma}_{2} \mathrm{SO}_{4}$ ?

## The Effect of pH on Solubility

The hydronium ion concentration can have a profound effect on the solubility of an ionic compound. If the compound contains the anion of a weak acid, addition of $\mathrm{H}_{3} \mathrm{O}^{+}$(from a strong acid) increases its solubility. Once again, Le Châtelier's principle explains why. In a saturated solution of calcium carbonate, for example,

$$
\mathrm{CaCO}_{3}(s) \rightleftharpoons \mathrm{Ca}^{2+}(a q)+\mathrm{CO}_{3}^{2-}(a q)
$$

Adding some strong acid introduces a large amount of $\mathrm{H}_{3} \mathrm{O}^{+}$, which immediately reacts with $\mathrm{CO}_{3}{ }^{2-}$ to form the weak acid $\mathrm{HCO}_{3}{ }^{-}$:

$$
\mathrm{CO}_{3}^{2-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \longrightarrow \mathrm{HCO}_{3}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

If enough $\mathrm{H}_{3} \mathrm{O}^{+}$is added, further reaction occurs to form carbonic acid, which decomposes immediately to $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$, and the gas escapes the container: As this sequence of changes shows, the net effect of added $\mathrm{H}_{3} \mathrm{O}^{+}$is a shift in the equilibrium position to the right, and more $\mathrm{CaCO}_{3}$ dissolves:
$\mathrm{CaCO}_{3}(s) \rightleftharpoons \mathrm{Ca}^{2+}+\mathrm{CO}_{3}{ }^{2-} \xrightarrow{\mathrm{H}_{3} \mathrm{O}^{+}} \mathrm{HCO}_{3}{ }^{-} \xrightarrow{\mathrm{H}_{3} \mathrm{O}^{+}} \mathrm{H}_{2} \mathrm{CO}_{3} \longrightarrow$

$$
\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}+\mathrm{Ca}^{2+}
$$

In fact, this example illustrates a qualitative field test for carbonate minerals because the $\mathrm{CO}_{2}$ bubbles vigorously (Figure 19.13).

In contrast, adding $\mathrm{H}_{3} \mathrm{O}^{+}$to a saturated solution of a compound with a strongacid anion, such as silver chloride, has no effect on the equilibrium position:

$$
\mathrm{AgCl}(s) \rightleftharpoons \mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q)
$$

Because $\mathrm{Cl}^{-}$ion is the conjugate base of a strong acid $(\mathrm{HCl})$, it can coexist in solution with high $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$. The $\mathrm{Cl}^{-}$does not leave the system, so the equilibrium position is not affected.

## SAMPLE PROBLEM 19.9 Predicting the Effect on Solubility of Adding Strong Acid

PROBLEM Write balanced equations to explain whether addition of $\mathrm{H}_{3} \mathrm{O}^{+}$from a strong acid affects the solubility of these ionic compounds:
(a) Lead(II) bromide
(b) Copper(II) hydroxide
(c) Iron(II) sulfide

PLAN We write the balanced dissolution equation and note the anion: Weak-acid anions react with $\mathrm{H}_{3} \mathrm{O}^{+}$and shift the equilibrium position toward more dissolution. Strong-acid anions do not react, so added $\mathrm{H}_{3} \mathrm{O}^{+}$has no effect.
SOLUTION (a) $\mathrm{PbBr}_{2}(s) \rightleftharpoons \mathrm{Pb}^{2+}(a q)+2 \mathrm{Br}^{-}(a q)$
No effect. $\mathrm{Br}^{-}$is the anion of HBr , a strong acid, so it does not react with $\mathrm{H}_{3} \mathrm{O}^{+}$.
(b) $\mathrm{Cu}(\mathrm{OH})_{2}(s) \rightleftharpoons \mathrm{Cu}^{2}(a q)+2 \mathrm{OH}^{-}(a q)$ Increases solubility. $\mathrm{OH}^{-}$is the anion of $\mathrm{H}_{2} \mathrm{O}$, a very weak acid, so it reacts with the added $\mathrm{H}_{3} \mathrm{O}$ :

$$
\mathrm{OH}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)
$$

$\mathrm{BaSO}_{4}$ imaging of a human large intestine.

Figure 19.13 Test for the presence of a carbonate. When a mineral that contains carbonate ion is treated with strong acid, the added $\mathrm{H}_{3} \mathrm{O}^{+}$shifts the equilibrium position of the carbonate solubility. More carbonate dissolves, and the carbonic acid that is formed breaks down to water and gaseous $\mathrm{CO}_{2}$.
(c) $\mathrm{FeS}(s)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{Fe}^{2+}(a q)+\mathrm{HS}^{-}(a q)+\mathrm{OH}^{-}(a q)$ Increases solubility. We noted earlier that the $\mathrm{S}^{2-}$ ion reacts immediately with water to form $\mathrm{HS}^{-}$and $\mathrm{OH}^{-}$. The added $\mathrm{H}_{3} \mathrm{O}^{+}$reacts with both of these weak-acid anions:

$$
\begin{aligned}
& \mathrm{HS}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{~S}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \\
& \mathrm{OH}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
$$

FOLLOW-UP PROBLEM 19.9 Write balanced equations to show how addition of $\mathrm{HNO}_{3}(a q)$ affects the solubility of these ionic compounds:
(a) Calcium fluoride
(b) Zinc sulfide
(c) Silver iodide

The principles of ionic equilibria are illustrated in the next Chemical Connections essay, on the carbonate equilibria that give rise to limestone caves.

## Predicting the Formation of a Precipitate: $\boldsymbol{Q}_{\text {sp }}$ vs. $\boldsymbol{K}_{\text {sp }}$

In Chapter 17 , we compared the values of $Q$ and $K$ to see if a reaction had reached equilibrium and, if not, in which net direction it would move until it did. We use the same approach here to see if a precipitate will form and, if not, what changes in ion concentrations will cause it to do so. As you know, $Q_{\text {sp }}=K_{\text {sp }}$ when the solution is saturated. If $Q_{\mathrm{sp}}$ is greater than $K_{\mathrm{sp}}$, the solution is momentarily supersaturated, and some solid precipitates until the remaining solution becomes saturated $\left(Q_{\mathrm{sp}}=K_{\mathrm{sp}}\right)$. If $Q_{\mathrm{sp}}$ is less than $K_{\mathrm{sp}}$, the solution is unsaturated, and no precipitate forms at that temperature (more solid can dissolve). To summarize,

- $Q_{\mathrm{sp}}=K_{\mathrm{sp}}:$ solution is saturated and no change occurs.
- $Q_{\mathrm{sp}}>K_{\mathrm{sp}}$ : precipitate forms until solution is saturated.
- $Q_{\mathrm{sp}}<K_{\mathrm{sp}}$ : solution is unsaturated and no precipitate forms.

Precipitation of $\mathrm{CaF}_{2}$.

## SAMPLE PROBLEM 19.10 Predicting Whether a Precipitate Will Form

PROBLEM A common laboratory method for preparing a precipitate is to mix solutions containing the component ions. Does a precipitate form when 0.100 L of $0.30 \mathrm{M} \mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}$ is mixed with 0.200 L of 0.060 M NaF ?
PLAN First, we decide which slightly soluble salt could form and look up its $K_{\text {sp }}$ value in Appendix C. To see whether mixing these solutions forms the precipitate, we find the initial ion concentrations by calculating the amount (mol) of each ion from its concentration and volume, and then dividing by the total volume because each solution dilutes the other. Finally, we write the ion-product expression, calculate $Q_{\mathrm{sp}}$, and compare $Q_{\text {sp }}$ with $K_{\text {sp }}$. SOLUTION The ions present are $\mathrm{Ca}^{2+}, \mathrm{Na}^{+}, \mathrm{F}^{-}$, and $\mathrm{NO}_{3}{ }^{-}$. All sodium and all nitrate salts are soluble (Table 4.1, p. 148), so the only possibility is $\mathrm{CaF}_{2}\left(K_{\mathrm{sp}}=3.2 \times 10^{-11}\right)$. Calculating the ion concentrations:

$$
\begin{aligned}
\text { Moles of } \mathrm{Ca}^{2+} & =0.30 \mathrm{M} \mathrm{Ca}^{2+} \times 0.100 \mathrm{~L}=0.030 \mathrm{~mol} \mathrm{Ca}^{2+} \\
{\left[\mathrm{Ca}^{2+}\right]_{\text {init }} } & =\frac{0.030 \mathrm{~mol} \mathrm{Ca}^{2+}}{0.100 \mathrm{~L}+0.200 \mathrm{~L}}=0.10 \mathrm{M} \mathrm{Ca}^{2+} \\
\text { Moles of } \mathrm{F}^{-} & =0.060 \mathrm{MF}^{-} \times 0.200 \mathrm{~L}=0.012 \mathrm{~mol} \mathrm{~F}^{-} \\
{\left[\mathrm{F}^{-}\right]_{\text {init }} } & =\frac{0.012 \mathrm{~mol} \mathrm{~F}^{-}}{0.100 \mathrm{~L}+0.200 \mathrm{~L}}=0.040 \mathrm{M} \mathrm{~F}^{-}
\end{aligned}
$$

Substituting into the ion-product expression and comparing $Q_{\mathrm{sp}}$ with $K_{\text {sp }}$ :

$$
Q_{\mathrm{sp}}=\left[\mathrm{Ca}^{2+}\right]_{\text {init }}\left[\mathrm{F}^{-}\right]_{\mathrm{init}}^{2}=(0.10)(0.040)^{2}=1.6 \times 10^{-4}
$$

Because $Q_{\mathrm{sp}}>K_{\mathrm{sp}}, \mathrm{CaF}_{2}$ will precipitate until $Q_{\mathrm{sp}}=3.2 \times 10^{-11}$.
CHECK Make sure you round off and quickly check the math. For example, $Q_{\text {sp }}=$ $\left(1 \times 10^{-1}\right)\left(4 \times 10^{-2}\right)^{2}=1.6 \times 10^{-4}$. With $K_{\text {sp }}$ so low, $\mathrm{CaF}_{2}$ must have a low solubility, and given the sizable concentrations being mixed, we would expect $\mathrm{CaF}_{2}$ to precipitate.
FOLLOW-UP PROBLEM 19.10 As a result of mineral erosion and biological activity, phosphate ion is common in natural waters, where it often precipitates as insoluble salts such as $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$. If $\left[\mathrm{Ca}^{2+}\right]_{\text {init }}=\left[\mathrm{PO}_{4}^{3-}\right]_{\text {init }}=1.0 \times 10^{-9} M$ in a given river, will $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ precipitate? $K_{\text {sp }}$ of $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ is $1.2 \times 10^{-29}$.

## Chemical Connections to Geology <br> Creation of a Limestone Cave

Limestone caves and the intricate structures within them provide striking evidence of the workings of aqueous ionic equilibria (Figure B19.1). The spires and vaults of these natural cathedrals are the products of reactions between carbonate rocks and the water that has run through them for millennia. Limestone is predominantly calcium carbonate $\left(\mathrm{CaCO}_{3}\right)$, a slightly soluble ionic compound with a $K_{\text {sp }}$ of $3.3 \times 10^{-9}$. This rocky material began accumulating in the Earth over 400 million years ago, and a relatively young cave, such as Howe Caverns in eastern New York State, began forming about 800,000 years ago.

Two key facts help us understand how limestone caves form:

1. Gaseous $\mathrm{CO}_{2}$ is in equilibrium with aqueous $\mathrm{CO}_{2}$ in natural waters:

$$
\mathrm{CO}_{2}(\mathrm{~g}) \stackrel{\mathrm{H}_{2} \mathrm{O}(t)}{\rightleftharpoons} \mathrm{CO}_{2}(\mathrm{aq})
$$

(equation 1)
The concentration of $\mathrm{CO}_{2}$ in the water is proportional to the partial pressure of $\mathrm{CO}_{2}(g)$ in contact with the water (Henry's law; Section 13.4):

$$
\left[\mathrm{CO}_{2}(a q)\right] \propto P_{\mathrm{CO}_{2}}
$$

Because of the continual release of $\mathrm{CO}_{2}$ from within the Earth (outgassing), the $P_{\mathrm{CO}_{2}}$ in soil-trapped air is higher than the $P_{\mathrm{CO}_{2}}$ in the atmosphere.
2. As discussed in the text, the presence of $\mathrm{H}_{3} \mathrm{O}^{+}(a q)$ increases the solubility of ionic compounds that contain the anion of a weak acid. The reaction of $\mathrm{CO}_{2}$ with water produces $\mathrm{H}_{3} \mathrm{O}^{+}$:

$$
\mathrm{CO}_{2}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{HCO}_{3}^{-}(a q)
$$

Thus, the presence of $\mathrm{CO}_{2}(\mathrm{aq})$ leads to the formation of $\mathrm{H}_{3} \mathrm{O}^{+}$, which increases the solubility of $\mathrm{CaCO}_{3}$. $\mathrm{CaCO}_{3}(s)+\mathrm{CO}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{A}^{2} \rightleftharpoons$ ago PDE
$\mathrm{Ca}^{2+}(a q)+2 \mathrm{HCO}_{3}^{-}(a q) \quad$ (equation 2)
Here is an overview of the principal cave-forming process in most limestone caves: As surface water trickles through cracks in

Figure B19.1 Limestone cave. The formations within this cave at Nerja, Málaga, Spain, result from subtle shifts in carbonate equilibria acting over millions of years.
the ground, it meets soil-trapped air with its high $P_{\mathrm{CO}_{2}}$. As a result, $\left[\mathrm{CO}_{2}(a q)\right]$ increases (equation 1 shifts to the right), and the solution becomes more acidic. When this $\mathrm{CO}_{2}$-rich water contacts limestone, more $\mathrm{CaCO}_{3}$ dissolves (equation 2 shifts to the right). As a result, more rock is carved out, more water flows in, and so on. Centuries pass and a cave slowly begins to form.

Eating its way through underground tunnels, some of the aqueous solution, largely dilute $\mathrm{Ca}\left(\mathrm{HCO}_{3}\right)_{2}$, passes through the ceiling of the growing cave. As it drips, it meets air, which has a lower $P_{\mathrm{CO}_{2}}$ than the soil, so some $\mathrm{CO}_{2}(a q)$ comes out of solution (equation 1 shifts to the left). This causes some $\mathrm{CaCO}_{3}$ to precipitate on the ceiling and on the floor below, where the drops land (equation 2 shifts to the left). Decades pass, and the ceiling bears an "icicle" of $\mathrm{CaCO}_{3}$, called a stalactite, while a spike of $\mathrm{CaCO}_{3}$, called a stalagmite, grows upward from the cave floor. With time, they meet to form a column of precipitated limestone.

The same chemical process can lead to different shapes. Standing pools of $\mathrm{Ca}\left(\mathrm{HCO}_{3}\right)_{2}$ solution form limestone "lily pads" or "corals." Cascades of solution form delicate limestone "draperies" on a cave wall, with fabulous colors arising from trace metal ions, such as iron (reddish brown) or copper (bluish green).

Recently, vast, spectacularly shaped deposits of gypsum $\left(\mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}\right.$; Figure B19.2) found in some limestone caves in Mexico point strongly to another process of cave formation. Certain bacteria found in abundance in these caves can survive at very low pH and consume hydrogen sulfide $\left(\mathrm{H}_{2} \mathrm{~S}\right)$, which leaks into the cave from oil deposits deep below it. The evidence shows that Etheseaudenie microbes use $\mathrm{O}_{2}$ to oxidize the $\mathrm{H}_{2} \mathrm{~S}$ to sulfuric acid $\left(\mathrm{H}_{2} \mathrm{SO}_{4}\right)$, a strong acid:
$\mathrm{H}_{2} \mathrm{~S}(g)+2 \mathrm{O}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \xrightarrow{\text { bacteria }} \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{HSO}_{4}^{-}(a q)$ The sulfuric acid contributes greatly to the formation of the cave.

Figure B19.2 Gypsum deposits. Formations of gypsum in the Chandelier Ballroom of Lechuguilla Cave in Mexico.

## SAMPLE PROBLEM 19.11 Using Molecular Scenes to Predict Whether a Precipitate Will Form

PROBLEM The following molecular scenes represent four solutions of silver (gray) and carbonate (black and red) ions that are above solid silver carbonate. (For clarity, the solid, other ions, and water are not shown.)

(a) Which scene best represents the solution at equilibrium with the solid?
(b) In which, if any, other scene(s) will additional solid be formed?
(c) Explain how, if at all, addition of a small volume of concentrated strong acid affects the $\left[\mathrm{Ag}^{+}\right]$in scene 4 and the mass of solid present.
PLAN (a) The solution of silver and carbonate ions in equilibrium with the solid $\left(\mathrm{Ag}_{2} \mathrm{CO}_{3}\right)$ should have the same relative numbers of cation and anion as appear in the formula. We examine the scenes to see which maintains a ratio of $2 \mathrm{Ag}^{+}$to $1 \mathrm{CO}_{3}{ }^{2-}$. (b) A solid forms whenever the ion product exceeds the $K_{\mathrm{sp}}$. We first calculate the value of $Q_{\mathrm{sp}}$ in each scene according to the ion-product expression and then see which, if any, exceeds the value for the solution from part (a). (c) The $\mathrm{CO}_{3}{ }^{2-}$ ion reacts with added $\mathrm{H}_{3} \mathrm{O}^{+}$, so adding strong acid will shift the equilibrium to the right. We write the equations and determine how a shift to the right affects $\left[\mathrm{Ag}^{+}\right]$and the mass of solid $\mathrm{Ag}_{2} \mathrm{CO}_{3}$.
SOLUTION (a) Scene 3 is the only one with $2 \mathrm{Ag}^{+}$to $1 \mathrm{CO}_{3}{ }^{2-}$ as in the solid's formula. (b) Calculating the ion products:

$$
\mathrm{Ag}_{2} \mathrm{CO}_{3}(s) \rightleftharpoons 2 \mathrm{Ag}^{+}(a q)+\mathrm{CO}_{3}^{2-}(a q) \quad Q_{\mathrm{sp}}=\left[\mathrm{Ag}^{+}\right]^{2}\left[\mathrm{CO}_{3}{ }^{2-}\right]
$$

Scene 1: $Q_{\text {sp }}=(2)^{2}(4)=16 \quad$ Scene 2: $Q_{\text {sp }}=(3)^{2}(3)=27$
Scene 3: $Q_{\mathrm{sp}}=(4)^{2}(2)=32 \quad$ Scene 4: $Q_{\mathrm{sp}}=(3)^{2}(4)=36$
Therefore, from scene $3, K_{\mathrm{sp}}=32$; the $Q_{\mathrm{sp}}$ value for scene 4 is the only other one that equals or exceeds 32 , so a precipitate of $\mathrm{Ag}_{2} \mathrm{CO}_{3}$ will form.
(c) Writing the equations:

1. $\quad \mathrm{Ag}_{2} \mathrm{CO}_{3}(s) \rightleftharpoons 2 \mathrm{Ag}^{+}(a q)+\mathrm{CO}_{3}{ }^{2-}(a q)$
2. $\mathrm{CO}_{3}^{2-}(a q)+2 \mathrm{H}_{3} \mathrm{O}^{+}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{CO}_{3}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 3 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g)$

The $\mathrm{CO}_{2}$ leaves as a gas, so adding $\mathrm{H}_{3} \mathrm{O}^{+}$shifts the equilibrium position of reaction 2 to the right. This change lowers the $\left[\mathrm{CO}_{3}{ }^{2-}\right]$ in reaction 1 , thereby causing more $\mathrm{CO}_{3}{ }^{2-}$ to form. As a result, more solid dissolves, which means that the $\left[\mathrm{Ag}^{+}\right]$increases and the mass of $\mathrm{Ag}_{2} \mathrm{CO}_{3}$ decreases.
CHECK (a) In scene 1, the formula has two $\mathrm{CO}_{3}{ }^{2-}$ per formula unit, not two $\mathrm{Ag}^{+}$. (b) Even though scene 4 has fewer $\mathrm{Ag}^{+}$ions than scene 3, its $Q_{\text {sp }}$ value is higher and exceeds the $K_{\text {sp }}$.
FOLLOW-UP PROBLEM 19.11 The following scenes represent four solutions of nickel(II) (black) and hydroxide (red and blue) ions that are above solid nickel(II) hydroxide. (For clarity, the solid, other ions, and water are not shown.)

(a) Which scene best depicts the solution at equilibrium with the solid?
(b) In which, if any, other scene(s) will additional solid be formed?
(c) Will addition of a small amount of concentrated strong acid or strong base affect the mass of solid present in any scene? Explain.

## Selective Precipitation of Ions

We can often separate one ion in a solution from another by exploiting differences in the solubility of their compounds with a given precipitating ion. In the process of selective precipitation, we add a solution of precipitating ion until the $Q_{\text {sp }}$ value of the more soluble compound is almost equal to its $K_{\text {sp }}$ value. This method ensures that the $K_{\mathrm{sp}}$ value of the less soluble compound is exceeded as much as possible. As a result, the maximum amount of the less soluble compound precipitates, but none of the more soluble compound does.

## SAMPLE PROBLEM 19.12 Separating lons by Selective Precipitation

PROBLEM A solution consists of 0.20 M MgCl 2 and $0.10 \mathrm{M} \mathrm{CuCl}_{2}$. Calculate the [ $\mathrm{OH}^{-}$] that would separate the metal ions as their hydroxides. $K_{\text {sp }}$ of $\mathrm{Mg}(\mathrm{OH})_{2}$ is $6.3 \times 10^{-10} ; K_{\text {sp }}$ of $\mathrm{Cu}(\mathrm{OH})_{2}$ is $2.2 \times 10^{-20}$.
PLAN The two hydroxides have the same formula type (1/2) (see p. 855), so we can compare their $K_{\text {sp }}$ values to see which is more soluble: $\mathrm{Mg}(\mathrm{OH})_{2}$ is about $10^{10}$ times more soluble than $\mathrm{Cu}(\mathrm{OH})_{2}$. Thus, $\mathrm{Cu}(\mathrm{OH})_{2}$ precipitates first. We want to precipitate as much $\mathrm{Cu}(\mathrm{OH})_{2}$ as possible without precipitating any $\mathrm{Mg}(\mathrm{OH})_{2}$. We solve for the $\left[\mathrm{OH}^{-}\right]$that will just give a saturated solution of $\mathrm{Mg}(\mathrm{OH})_{2}$ because this $\left[\mathrm{OH}^{-}\right]$will precipitate the greatest amount of $\mathrm{Cu}^{2+}$ ion. As confirmation, we calculate the $\left[\mathrm{Cu}^{2+}\right]$ remaining to see if the separation was accomplished.
SOLUTION Writing the equations and ion-product expressions:

$$
\begin{aligned}
\mathrm{Mg}(\mathrm{OH})_{2}(s) \rightleftharpoons \mathrm{Mg}^{2+}(a q)+2 \mathrm{OH}^{-}(a q) & K_{\text {sp }}=\left[\mathrm{Mg}^{2+}\right]\left[\mathrm{OH}^{-}\right]^{2} \\
\mathrm{Cu}(\mathrm{OH})_{2}(s) \rightleftharpoons \mathrm{Cu}^{2+}(a q)+2 \mathrm{OH}^{-}(a q) & K_{\text {sp }}=\left[\mathrm{Cu}^{2+}\right]\left[\mathrm{OH}^{-}\right]^{2}
\end{aligned}
$$

Calculating the $\left[\mathrm{OH}^{-}\right]$that gives a saturated $\mathrm{Mg}(\mathrm{OH})_{2}$ solution:

$$
\left[\mathrm{OH}^{-}\right]=\sqrt{\frac{K_{\mathrm{sp}}}{\left[\mathrm{Mg}^{2+}\right]}}=\sqrt{\frac{6.3 \times 10^{-10}}{0.20}}=5.6 \times 10^{-5} \mathrm{M}
$$

This is the maximum $\left[\mathrm{OH}^{-}\right]$that will not precipitate $\mathrm{Mg}^{2+}$ ion.
Calculating the $\left[\mathrm{Cu}^{2+}\right]$ remaining in the solution with this $\left[\mathrm{OH}^{-}\right]$:

$$
\left[\mathrm{Cu}^{2+}\right]=\frac{K_{\mathrm{sp}}}{\left[\mathrm{OH}^{-}\right]^{2}}=\frac{2.2 \times 10^{-20}}{\left(5.6 \times 10^{-5}\right)^{2}}=7.0 \times 10^{-12} \mathrm{M}
$$

Since the initial $\left[\mathrm{Cu}^{2+}\right]$ was 0.10 M , virtually all the $\mathrm{Cu}^{2+}$ ion is precipitated.
CHECK Rounding, we find that the $\left[\mathrm{OH}^{-}\right]$seems right: $\sim \sqrt{\left(6 \times 10^{-10}\right) / 0.2}=5 \times 10^{-5}$. The $\left[\mathrm{Cu}^{2+}\right]$ remaining also seems correct: $\left(200 \times 10^{-22}\right) /\left(5 \times 10^{-5}\right)^{2}=8 \times 10^{-12}$.
COMMENT Often, more than one approach will accomplish the same analytical step. Another possibility in this case is to add excess ammonia to make the solution basic enough to precipitate both hydroxides:

$$
\begin{aligned}
& \mathrm{Mg}^{2+}(a q)+2 \mathrm{NH}_{3}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{Mg}(\mathrm{OH})_{2}(s)+2 \mathrm{NH}_{4}^{+}(a q) \\
& \mathrm{Cu}^{2+}(a q)+2 \mathrm{NH}_{3}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{Cu}(\mathrm{OH})_{2}(s)+2 \mathrm{NH}_{4}^{+}(a q)
\end{aligned}
$$

Then, the $\mathrm{Cu}(\mathrm{OH})_{2}$ dissolves in excess $\mathrm{NH}_{3}$ by forming a soluble complex ion:

$$
\mathrm{Cu}(\mathrm{OH})_{2}(s)+4 \mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}(a q)+2 \mathrm{OH}^{-}(a q)
$$

FOLLOW-UP PROBLEM 19.12 A solution containing two alkaline earth metal ions is made from $0.050 \mathrm{M} \mathrm{BaCl}_{2}$ and $0.025 \mathrm{M} \mathrm{CaCl}_{2}$. What concentration of $\mathrm{SO}_{4}{ }^{2-}$ must be present to leave $99.99 \%$ of only one of the cations in solution? $K_{\text {sp }}$ of $\mathrm{BaSO}_{4}$ is $1.1 \times 10^{-10}$, and $K_{\text {sp }}$ of $\mathrm{CaSO}_{4}$ is $2.4 \times 10^{-5}$.

Sometimes two or more types of ionic equilibria are controlled simultaneously to precipitate ions selectively. This approach is used commonly to separate ions as their sulfides, so the $\mathrm{HS}^{-}$ion is the precipitating ion. In the manner used in Sample Problem 19.12, we control the $\left[\mathrm{HS}^{-}\right.$] to exceed the $K_{\text {sp }}$ value of one metal sulfide but not another. We exert this control on the [ $\mathrm{HS}^{-}$] by controlling $\mathrm{H}_{2} \mathrm{~S}$ dissociation because $\mathrm{H}_{2} \mathrm{~S}$ is the source of $\mathrm{HS}^{-}$; we control $\mathrm{H}_{2} \mathrm{~S}$ dissociation by adjusting the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$:

$$
\mathrm{H}_{2} \mathrm{~S}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{HS}^{-}(a q)
$$

These interactions are controlled in the following way: If we add strong acid to the solution, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$is high, so $\mathrm{H}_{2} \mathrm{~S}$ dissociation shifts to the left, which decreases [ $\mathrm{HS}^{-}$]. With a low $\left[\mathrm{HS}^{-}\right.$], the less soluble sulfide precipitates. Conversely, if we add strong base, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$is low, so $\mathrm{H}_{2} \mathrm{~S}$ dissociation shifts to the right, which increases $\left[\mathrm{HS}^{-}\right]$, and then the more soluble sulfide precipitates. In essence, what we do is shift one equilibrium system $\left(\mathrm{H}_{2} \mathrm{~S}\right.$ dissociation) by adjusting a second $\left(\mathrm{H}_{2} \mathrm{O}\right.$ ionization) to control a third (metal sulfide solubility).

As the upcoming Chemical Connections essay demonstrates, the principles of ionic equilibria often help us understand the chemical basis of complex environmental problems and may provide ways to solve them.

## Section Summary

As a first approximation, the dissolved portion of a slightly soluble salt dissociates completely into ions. - In a saturated solution, the ions are in equilibrium with the solid, and the product of the ion concentrations, each raised to the power of its subscript in the compound's formula, has a constant value ( $Q_{\mathrm{sp}}=K_{\mathrm{sp}}$ ). - The value of $K_{\text {sp }}$ can be obtained from the solubility, and vice versa. • Adding a common ion lowers an ionic compound's solubility. • Adding $\mathrm{H}_{3} \mathrm{O}^{+}$(lowering the pH ) increases a compound's solubility if the anion of the compound is that of a weak acid. - If $Q_{\mathrm{sp}}>K_{\mathrm{sp}}$ for an ionic compound, a precipitate forms when two solutions, each containing one of the compound's ions, are mixed. - Limestone caves result from shifts in the $\mathrm{CaCO}_{3} / \mathrm{CO}_{2}$ equilibrium system. - Lakes bounded by limestone-rich soils form buffer systems that prevent harmful acidification. - lons are precipitated selectively by adding a precipitating ion until the $K_{\mathrm{sp}}$ of one compound is exceeded as much as possible without exceeding the $K_{\text {sp }}$ of the other. An extension of this approach simultaneously controls an equilibrium system that contains the precipitating ion itself.

### 19.4 EQUILIBRIA INVOLVING COMPLEX IONS

The final type of aqueous ionic equilibrium we consider involves a different kind of ion than we've examined up to now. A simple ion, such as $\mathrm{Na}^{+}$or $\mathrm{SO}_{4}{ }^{2-}$, consists of one or a few bound atoms, with an excess or deficit of electrons. A complex ion consists of a central metal ion covalently bonded to two or more anions or molecules, called ligands. Hydroxide, chloride, and cyanide ions are some ionic ligands; water, carbon monoxide, and ammonia are some molecular ligands. In the complex ion $\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+}$, for example, $\mathrm{Cr}^{3+}$ is the central metal ion and six $\mathrm{NH}_{3}$ molecules are the ligands, giving an overall $3+$ charge (Figure 19.14).

As we noted in Section 18.9, all complex ions are Lewis adducts. The metal ion acts as a Lewis acid (accepts an electron pair) and the ligand acts as a Lewis base (donates an electron pair). The acidic hydrated metal ions that we discussed in Section 18.6 are complex ions with water molecules as ligands. In Chapter 23, we discuss the transition metals and the structures and properties of the numerous complex ions they form. Our focus here is on equilibria of hydrated ions with ligands other than water.

## Formation of Complex Ions

Whenever a metal ion enters water, a complex ion forms, with water as the ligand. In many cases, when we treat this hydrated cation with a solution of another ligand, the bound water molecules exchange for the other ligand. For example, a hydrated $\mathrm{M}^{2+}$ ion, $\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}$, forms $\mathrm{M}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}$ in aqueous $\mathrm{NH}_{3}$ :

$$
\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}(a q)+4 \mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{M}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

At equilibrium, this system is expressed by a ratio of concentration terms whose form follows that of any other equilibrium expression:

$$
K_{\mathrm{c}}=\frac{\left[\mathrm{M}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\right]\left[\mathrm{H}_{2} \mathrm{O}\right]^{4}}{\left[\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}\right]\left[\mathrm{NH}_{3}\right]^{4}}
$$

## Chemical Connections to Environmental Science

## The Acid-Rain Problem

The adverse effect of an industrial society on the environment is clear in the problem of acid rain, the deposition of acids, formed as a result of human activity, that occurs in wet form as rain, snow, and fog, or in dry form on solid particles. Acidic precipitation has been recorded in all parts of the United States, in Canada, Mexico, the Amazon basin, throughout Europe and Russia and many parts of Asia, and even at the North and South Poles. We've addressed several aspects of this problem earlier; now, let's examine some effects of acidic precipitation on biological and mineral systems and see how to prevent them. The strong acids $\mathrm{H}_{2} \mathrm{SO}_{4}$ and $\mathrm{HNO}_{3}$ cause the greatest concern (Figure B19.3):

- Formation of sulfuric acid. Sulfur dioxide $\left(\mathrm{SO}_{2}\right)$ formed primarily by the burning of high-sulfur coal, forms sulfurous acid $\left(\mathrm{H}_{2} \mathrm{SO}_{3}\right)$ in contact with water. Oxidants, such as hydrogen peroxide $\left(\mathrm{H}_{2} \mathrm{O}_{2}\right)$ and ozone $\left(\mathrm{O}_{3}\right)$, that are present as pollutants in the atmosphere also dissolve in the water in clouds and oxidize the sulfurous acid to sulfuric acid:

$$
\mathrm{H}_{2} \mathrm{O}_{2}(a q)+\mathrm{H}_{2} \mathrm{SO}_{3}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

$\mathrm{SO}_{2}$ is also oxidized directly by atmospheric hydroxyl radicals to sulfur trioxide $\left(\mathrm{SO}_{3}\right)$, which forms $\mathrm{H}_{2} \mathrm{SO}_{4}$ in contact with water.

- Formation of nitric acid. Nitrogen oxides (collectively known as $\mathrm{NO}_{x}$ ) form through the reaction of $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$. NO is formed during high-temperature combustion, primarily in car engines and electric power plants and it forms $\mathrm{NO}_{2}$ and $\mathrm{HNO}_{3}$ in air in the process that creates snoog (p. 600). At night, $\mathrm{NO}_{x}$ is converted to $\mathrm{N}_{2} \mathrm{O}_{5}$, which hydrolyzes to $\mathrm{HNO}_{3}$ in the presence of water. Ammonium salts, deposited as $\mathrm{NH}_{4} \mathrm{HSO}_{4}$ or $\mathrm{NH}_{4} \mathrm{NO}_{3}$, produce $\mathrm{HNO}_{3}$ in soil through biochemical oxidation.

How does the pH of acidic precipitation compare with that of natural waters? Normal rainwater is weakly acidic because it contains dissolved $\mathrm{CO}_{2}$ from the air:

$$
\mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{HCO}_{3}^{-}(a q)
$$

Based on the volume percent of $\mathrm{CO}_{2}$ in air, the solubility of $\mathrm{CO}_{2}$ in water, and the $K_{\mathrm{a} 1}$ of $\mathrm{H}_{2} \mathrm{CO}_{3}$, the pH of normal rainwater is about 5.6 (see Problem 19.148 at the end of the chapter). In stark contrast, the average pH of rainfall in many parts of the United States was 4.2 in 1984, representing 25 times as much $\mathrm{H}_{3} \mathrm{O}^{+}$. Worldwide, rain in Sweden had a pH of 2.7, about the same as vinegar. Rain in Wheeling, West Virginia, had a pH of 1.8 , less than that of lemon juice. Acidic fog in California sometimes has a pH of 1.6 as evaporation from the particles concentrates the acid.

Such high $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$is very destructive to living things. Some fish and shellfish die at pH values between 4.5 and 5.0. The young of most species are generally most sensitive. At pH 5, most fish eggs cannot hatch. With tens of thousands of rivers and lakes around the world becoming acidified, the loss of fish became a major concern long ago. In addition, acres of forest have been harmed by the acid, which removes nutrients and releases toxic substances from the soil (Figure B19.4 on the next page).

Many principles of aqueous equilibria bear directly on the effects of acid rain. The aluminosilicates that make up most soils are extremely insoluble in water. In these materials, the $\mathrm{Al}^{3+}$ ion is bonded to $\mathrm{OH}^{-}$and $\mathrm{O}^{2-}$ ions (see the Gallery in Chapter 14, p. 592). Continual contact with water at $\mathrm{pH}<5$ causes these and Fether Al-bearing substances to react through a complex series of equilibria to release some of the bound $\mathrm{Al}^{3+}$, which is toxic to fish and plants. Along with dissolved $\mathrm{Al}^{3+}$ ions, acid rain dissolves and carries away $\mathrm{Ca}^{2+}$ and $\mathrm{Mg}^{2+}$ ions from the soil, which serve as nutrients for plants and animals.
(continued)

Figure B19.3 Formation of acidic precipitation. A complex interplay of human activities, atmospheric chemistry, and environmental distribution leads to acidic precipitation and its harmful effects. Car exhaust and power plant waste gases contain lower oxides of nitrogen and sulfur. These are oxidized in the atmosphere to higher oxides
$\left(\mathrm{NO}_{2}, \mathrm{SO}_{3}\right)$, which react with moisture to form acidic rain, snow, and fog. In contact with acidic precipitation, many lakes become acidified, whereas limestone-bounded lakes form a carbonate buffer that prevents acidification.

## Chemical Connections continued

Figure B19.4 A forest damaged by acid rain.

Marble and limestone (both primarily $\mathrm{CaCO}_{3}$ ) in buildings and monuments react with sulfuric acid to form gypsum $\left(\mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}\right)$, which flakes off (Figure B19.5). Ironically, the same chemical process that destroys these structures is responsible for saving those lakes that lie on and are bounded by limestone-rich soil. Limestone dissolves sufficiently in lake water to form an $\mathrm{HCO}_{3}{ }^{-} / \mathrm{CO}_{3}{ }^{2-}$ buffer solution capable of absorbing the incoming $\mathrm{H}_{3} \mathrm{O}^{+}$and maintaining a mildly basic $\mathrm{pH}^{\circ}$.

$$
\mathrm{CO}_{3}{ }^{2-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \rightleftharpoons \mathrm{HCO}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Acidified lakes and rivers that are in contact with granite and other weathering-resistant bedrock can be remediated by liming (treating with limestone). This approach is expensive and, at best, only a stopgap because the lakes are acidic again within several years, so it is more cost effective to treat the problem at its source.

As we pointed out earlier (see Chemical Connections, Chapter $6, \mathrm{p} .256$ ), the principal means of controlling sulfur dioxide is by "scrubbing" the emissions from power plants with limestone.

Figure B19.5 The effect of acid rain on marble statuary. Calcium carbonate, which is the major component of marble, decomposes when exposed to acid rain. These photos, taken many years apart, of a gargoyle at Notre Dame Cathedral in Paris demonstrate this decomposition.

Both dry and wet scrubbers are used. Another method reduces some of the $\mathrm{SO}_{2}$ with methane, coal, or $\mathrm{H}_{2} \mathrm{~S}$, and the mixture is converted catalytically to sulfur, which is sold as a byproduct:

$$
16 \mathrm{H}_{2} \mathrm{~S}(g)+8 \mathrm{SO}_{2}(g) \longrightarrow 3 \mathrm{~S}_{8}(s)+16 \mathrm{H}_{2} \mathrm{O}(l)
$$

Burning low-sulfur coal to reduce $\mathrm{SO}_{2}$ formation is sometimes an option, but such coal deposits are rare and expensive to mine. Alternatively, coal can be converted into gaseous and liquid lowFsulfinfods acechemical Connections, p. 256). The sulfur is removed $\left(\right.$ as $\left.\mathrm{H}_{2} \mathrm{~S}\right)$ in an acid-gas scrubber after gasification.

Through the use of a catalytic converter in an auto exhaust system, $\mathrm{NO}_{x}$ species are reduced to $\mathrm{N}_{2}$. In power plants, the amount of $\mathrm{NO}_{x}$ is decreased by adjusting combustion conditions, but it also can be removed from the hot stack gases by treatment with ammonia in the presence of a heterogeneous catalyst:

$$
4 \mathrm{NO}(g)+4 \mathrm{NH}_{3}(g)+\mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{~N}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)
$$

Progress in North America and Europe, primarily by reducing power-plant emissions, has resulted in increased pH of rainfall, and some surface waters have recovered. Further progress is expected under current legislation, but, in much of eastern North America and the sensitive regions of northern Europe, additional measures are needed for full recovery.

$$
\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}(a q)+\mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\left(\mathrm{NH}_{3}\right)^{2+}(a q) \stackrel{3 \mathrm{NH}_{3}}{3 \text { more steps }} \mathrm{M}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(I)
$$

Once again, because the concentration of water is essentially constant in aqueous reactions, we incorporate it into $K_{\mathrm{c}}$ and obtain the expression for a new equilibrium constant, the formation constant, $\boldsymbol{K}_{\mathbf{f}}$ :

$$
K_{\mathrm{f}}=\frac{K_{\mathrm{c}}}{\left[\mathrm{H}_{2} \mathrm{O}\right]^{4}}=\frac{\left[\mathrm{M}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\right]}{\left[\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}\right]\left[\mathrm{NH}_{3}\right]^{4}}
$$

At the molecular level (Figure 19.15), the actual process is stepwise, with ammonia molecules replacing water molecules one at a time to give a series of intermediate species, each with its own formation constant:

$$
\begin{aligned}
& K_{\mathrm{f} 1}=\frac{\left[\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\left(\mathrm{NH}_{3}\right)^{2+}\right]}{\left[\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}\right]\left[\mathrm{NH}_{3}\right]} \\
& \mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\left(\mathrm{NH}_{3}\right)^{2+}(a q)+\mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left(\mathrm{NH}_{3}\right)_{2}{ }^{2+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \\
& K_{\mathrm{f} 2}=\frac{\left[\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left(\mathrm{NH}_{3}\right)_{2}{ }^{2+}\right]}{\left[\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\left(\mathrm{NH}_{3}\right)^{2+}\right]\left[\mathrm{NH}_{3}\right]} \\
& \mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left(\mathrm{NH}_{3}\right)_{2}{ }^{2+}(a q)+\mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)\left(\mathrm{NH}_{3}\right)_{3}{ }^{2+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \\
& K_{\mathrm{f} 3}=\frac{\left[\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)\left(\mathrm{NH}_{3}\right)_{3}{ }^{2+}\right]}{\left[\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left(\mathrm{NH}_{3}\right)_{2}{ }^{2+}\right]\left[\mathrm{NH}_{3}\right]} \\
& \mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)\left(\mathrm{NH}_{3}\right)_{3}{ }^{2+}(a q)+\mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{M}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \\
& K_{\mathrm{f} 4}=\frac{\left[\mathrm{M}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\right]}{\left[\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)\left(\mathrm{NH}_{3}\right)_{3}{ }^{2+}\right]\left[\mathrm{NH}_{3}\right]}
\end{aligned}
$$

The sum of the equations gives the overall equation, so the product of the individual formation constants gives the overall formation constant:

$$
K_{\mathrm{f}}=K_{\mathrm{f} 1} \times K_{\mathrm{f} 2} \times K_{\mathrm{f} 3} \times K_{\mathrm{f} 4}
$$

In this case, the $K_{\mathrm{f}}$ for each step is much larger than 1 because ammonia is a stronger Lewis base than water. Therefore, if we add excess ammonia to the $\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}$ solution, the $\mathrm{H}_{2} \mathrm{O}$ ligands are replaced and essentially all the $\mathrm{M}^{2+}$ ion exists as $\mathrm{M}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}$.

Table 19.4 (and Appendix C) shows the formation constants of some complex ions. Notice that the $K_{\mathrm{f}}$ values are all $10^{6}$ or greater, which means that these ions form readily. Because of this behavior, complex-ion formation is used to retrieve a metal from its ore, eliminate a toxic or unwanted metal ion from a solution, or convert a metal ion to a different form, as Sample Problem 19.13 shows for the zinc ion.

Figure 19.15 The stepwise exchange of $\mathrm{NH}_{3}$ for $\mathrm{H}_{2} \mathrm{O}$ in $\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}$. The ligands of a complex ion can exchange for other ligands. When ammonia is added to a solution of the hydrated $\mathrm{M}^{2+}$ ion, $\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}, \mathrm{NH}_{3}$ molecules replace the bound $\mathrm{H}_{2} \mathrm{O}$ molecules one at a time to form the $\mathrm{M}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}$ ion. The molecularscale views show the first exchange and the fully ammoniated ion.

Table 19.4 Formation Constants ${ }^{\left(K_{f}\right) \text { of Some Complex }}$ lons at $25^{\circ} \mathrm{C}$

| Complex lon | $K_{f}$ |
| :--- | :--- |
| $\mathrm{Ag}(\mathrm{CN})_{2}{ }^{-}$ | $3.0 \times 10^{20}$ |
| $\left.\mathrm{Ag}(\mathrm{NH})_{2}\right)_{2}$ | $1.7 \times 10^{7}$ |
| $\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}$ | $4.7 \times 10^{13}$ |
| $\mathrm{AlF}_{6}{ }^{-}{ }^{2}$ | $4 \times 10^{19}$ |
| $\mathrm{Al}(\mathrm{OH})_{4}{ }^{-}$ | $3 \times 10^{33}$ |
| $\mathrm{Be}(\mathrm{OH})_{4}{ }^{2-}$ | $4 \times 10^{18}$ |
| $\mathrm{CdI}_{4}{ }^{2-}$ | $1 \times 10^{6}$ |
| $\mathrm{Co}(\mathrm{OH})_{4}{ }^{2-}$ | $5 \times 10^{9}$ |
| $\mathrm{Cr}(\mathrm{OH})_{4}$ | $8.0 \times 10^{29}$ |
| $\left.\mathrm{Cu}(\mathrm{NH})_{3}\right)_{4}{ }^{2+}$ | $5.6 \times 10^{11}$ |
| $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}$ | $3 \times 10^{35}$ |
| $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$ | $4.0 \times 10^{43}$ |
| $\mathrm{Hg}(\mathrm{CN})_{4}{ }^{2-}$ | $9.3 \times 10^{38}$ |
| $\mathrm{Ni}(\mathrm{NH})_{3}{ }_{6}{ }^{2+}$ | $2.0 \times 10^{8}$ |
| $\mathrm{~Pb}(\mathrm{OH})_{3}$ | $8 \times 10^{13}$ |
| $\mathrm{Sn}(\mathrm{OH})_{3}{ }^{-}$ | $3 \times 10^{25}$ |
| $\mathrm{Zn}(\mathrm{CN})_{4}{ }^{2-}$ | $4.2 \times 10^{19}$ |
| $\left.\mathrm{Zn}(\mathrm{NH})_{3}\right)_{4}{ }^{2+}$ | $7.8 \times 10^{8}$ |
| $\mathrm{Zn}(\mathrm{OH})_{4}{ }^{2-}$ | $3 \times 10^{15}$ |

## SAMPLE PROBLEM 19.13 Calculating the Concentration of a Complex Ion

PROBLEM An industrial chemist converts $\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}$ to the more stable $\mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}$ by mixing 50.0 L of $0.0020 \mathrm{M} \mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}$ and 25.0 L of $0.15 \mathrm{M}_{3}$. What is the final $\left[\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}\right]$ ? $K_{\mathrm{f}}$ of $\mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}$ is $7.8 \times 10^{8}$.
PLAN We write the equation and the $K_{\mathrm{f}}$ expression and use a reaction table to calculate the equilibrium concentrations. To set up the table, we must first find $\left[\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}\right]_{\text {init }}$ and $\left[\mathrm{NH}_{3}\right]_{\text {init }}$. We are given the individual volumes and molar concentrations, so we find the moles and divide by the total volume, because the solutions are mixed. With the large excess of $\mathrm{NH}_{3}$ and high $K_{\mathrm{f}}$, we assume that almost all the $\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}$ is converted to $\mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}$. Because $\left[\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}\right.$ ] at equilibrium is very small, we use $x$ to represent it. SOLUTION Writing the equation and the $K_{\mathrm{f}}$ expression:

$$
\begin{gathered}
\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}(a q)+4 \mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l) \\
K_{\mathrm{f}}=\frac{\left[\mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\right]}{\left[\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}\right]\left[\mathrm{NH}_{3}\right]^{4}}
\end{gathered}
$$

Finding the initial reactant concentrations:

$$
\begin{aligned}
{\left[\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}\right]_{\text {init }} } & =\frac{50.0 \mathrm{~L} \times 0.0020 \mathrm{M}}{50.0 \mathrm{~L}+25.0 \mathrm{~L}}=1.3 \times 10^{-3} \mathrm{M} \\
{\left[\mathrm{NH}_{3}\right]_{\text {init }} } & =\frac{25.0 \mathrm{~L} \times 0.15 \mathrm{M}}{50.0 \mathrm{~L}+25.0 \mathrm{~L}}=5.0 \times 10^{-2} \mathrm{M}
\end{aligned}
$$

 $\mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}$, so we set up the table with $x=\left[\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}\right]$ at equilibrium. Because 4 mol of $\mathrm{NH}_{3}$ is needed per mole of $\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}$, the change in $\left[\mathrm{NH}_{3}\right]$ is

$$
\left[\mathrm{NH}_{3}\right]_{\text {reacted }} \approx 4\left(1.3 \times 10^{-3} M\right)=5.2 \times 10^{-3} M \quad \text { and } \quad\left[\mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\right] \approx 1.3 \times 10^{-3} \mathrm{M}
$$

| Concentration $(M)$ | $\mathrm{Zn}\left(\mathrm{H}_{2} \mathbf{O}\right)_{4}{ }^{2+}(a q)$ | + | $4 \mathrm{NH}_{3}(a q)$ | $\mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)$ |
| :--- | :---: | :---: | :---: | :---: |
| Initial | $1.3 \times 10^{-3}$ | $5.0 \times 10^{-2}$ | 0 | - |
| Change | $\sim\left(-1.3 \times 10^{-3}\right)$ | $\sim\left(-5.2 \times 10^{-3}\right)$ | $\sim\left(+1.3 \times 10^{-3}\right)$ | - |
| Equilibrium | $x$ | $4.5 \times 10^{-2}$ | $1.3 \times 10^{-3}$ | - |

Solving for $x$, the $\left[\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}\right]$ remaining at equilibrium:

$$
\begin{aligned}
K_{\mathrm{f}} & =\frac{\left[\mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}\right]}{\left[\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}\right]\left[\mathrm{NH}_{3}\right]^{4}}=7.8 \times 10^{8} \approx \frac{1.3 \times 10^{-3}}{x\left(4.5 \times 10^{-2}\right)^{4}} \\
x & =\left[\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}\right] \approx 4.1 \times 10^{-7} \mathrm{M}
\end{aligned}
$$

CHECK The $K_{\mathrm{f}}$ is large, so we expect the $\left[\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}\right]$ remaining to be very low.
FOLLOW-UP PROBLEM 19.13 Cyanide ion is toxic because it forms stable complex ions with the $\mathrm{Fe}^{3+}$ ion in certain iron-containing proteins engaged in energy production. To study this effect, a biochemist mixes 25.5 mL of $3.1 \times 10^{-2} M \mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$ with 35.0 mL of 1.5 M NaCN . What is the final $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\right] ? K_{\mathrm{f}}$ of $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}$ is $4.0 \times 10^{43}$.

## Complex Ions and the Solubility of Precipitates

In Section 19.3, you saw that $\mathrm{H}_{3} \mathrm{O}^{+}$increases the solubility of a slightly soluble ionic compound if its anion is that of a weak acid. Similarly, a ligand increases the solubility of a slightly soluble ionic compound if it forms a complex ion with the cation. For example, zinc sulfide is very slightly soluble:

$$
\mathrm{ZnS}(s)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{Zn}^{2+}(a q)+\mathrm{HS}^{-}(a q)+\mathrm{OH}^{-}(a q) \quad K_{\mathrm{sp}}=2.0 \times 10^{-22}
$$

When we add some 1.0 M NaCN , the $\mathrm{CN}^{-}$ions act as ligands and react with the small amount of $\mathrm{Zn}^{2+}(a q)$ to form the complex ion $\mathrm{Zn}(\mathrm{CN})_{4}{ }^{2-}$ :

$$
\mathrm{Zn}^{2+}(a q)+4 \mathrm{CN}^{-}(a q) \rightleftharpoons \mathrm{Zn}(\mathrm{CN})_{4}^{2-}(a q) \quad K_{\mathrm{f}}=4.2 \times 10^{19}
$$

To see the effect of complex-ion formation on the solubility of ZnS , we add the equations and, therefore, multiply their equilibrium constants:

$$
\begin{gathered}
\mathrm{ZnS}(s)+4 \mathrm{CN}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{Zn}(\mathrm{CN})_{4}^{2-}(a q)+\mathrm{HS}^{-}(a q)+\mathrm{OH}^{-}(a q) \\
K_{\text {overall }}=K_{\mathrm{sp}} \times K_{\mathrm{f}}=\left(2.0 \times 10^{-22}\right)\left(4.2 \times 10^{19}\right)=8.4 \times 10^{-3}
\end{gathered}
$$

The overall equilibrium constant increased by more than a factor of $10^{19}$ in the presence of the ligand; this reflects the increased amount of ZnS in solution.

## SAMPLE PROBLEM 19.14 Calculating the Effect of Complex-Ion

 Formation on SolubilityPROBLEM In black-and-white film developing (see photo), excess AgBr is removed from the film negative by "hypo," an aqueous solution of sodium thiosulfate $\left(\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}\right)$, which forms the complex ion $\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}$. Calculate the solubility of AgBr in (a) $\mathrm{H}_{2} \mathrm{O}$; (b) 1.0 M hypo. $K_{\mathrm{f}}$ of $\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}$ is $4.7 \times 10^{13}$ and $K_{\text {sp }}$ of AgBr is $5.0 \times 10^{-13}$.
PLAN (a) After writing the equation and the ion-product expression, we use the given $K_{\text {sp }}$ to solve for $S$, the molar solubility of AgBr . (b) In hypo, $\mathrm{Ag}^{+}$forms a complex ion with $\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}$, which shifts the equilibrium and dissolves more AgBr . We write the complex-ion equation and add it to the equation for dissolving AgBr to obtain the overall equation for dissolving AgBr in hypo. We multiply $K_{\mathrm{sp}}$ by $K_{\mathrm{f}}$ to find $K_{\text {overall }}$. To find the solubility of AgBr in hypo, we set up a reaction table, with $S=\left[\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}\right]$, substitute into the expression for $K_{\text {overall }}$, and solve for $S$.
SOLUTION (a) Solubility in water. Writing the equation for the saturated solution and the ion-product expression:

$$
\operatorname{AgBr}(s) \rightleftharpoons \mathrm{Ag}^{+}(a q)+\mathrm{Br}^{-}(a q) \quad K_{\mathrm{sp}}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Br}^{-}\right]
$$

Solving for solubility $(S)$ directly from the equation: We know that

$$
S=[\mathrm{AgBr}]_{\text {dissolved }}=\left[\mathrm{Ag}^{+}\right]=\left[\mathrm{Br}^{-}\right]
$$

Thus,

$$
K_{\mathrm{sp}}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{Br}^{-}\right]=S^{2}=5.0 \times 10^{-13}
$$

$$
S=7.1 \times 10^{-7} M
$$

(b) Solubility in 1.0 M hypo. Writing the overall equation:

$$
\begin{aligned}
\mathrm{AgBr}(s) & \rightleftharpoons \mathrm{Ag}^{+}(a q)+\mathrm{Br}^{-}(a q) \\
\mathrm{Ag}^{+}(a q)+2 \mathrm{~S}_{2} \mathrm{O}_{3}{ }^{2-}(a q) & \rightleftharpoons \mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}(a q) \\
\mathrm{AgBr}(s)+2 \mathrm{~S}_{2} \mathrm{O}_{3}{ }^{2-}(a q) & \rightleftharpoons \mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}(a q)+\mathrm{Br}^{-}(a q)
\end{aligned}
$$

Calculating $K_{\text {overall }}$ :

$$
K_{\text {overall }}=\frac{\left[\mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}\right]\left[\mathrm{Br}^{-}\right]}{\left[\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}\right]^{2}}=K_{\mathrm{sp}} \times K_{\mathrm{f}}=\left(5.0 \times 10^{-13}\right)\left(4.7 \times 10^{13}\right)=24
$$

Setting up a reaction table, with $S=[\mathrm{AgBr}]_{\text {dissolved }}=\left[\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}\right]$ :

| Concentration $(\mathbf{M})$ | $\mathbf{A g B r}(\mathbf{s})+\mathbf{2 S}_{\mathbf{2}} \mathbf{0}_{\mathbf{3}}{ }^{\mathbf{2 -}}(\mathbf{a q})$ | $\rightleftharpoons$ | $\mathbf{A g}\left(\mathbf{S}_{\mathbf{2}} \mathbf{0}_{\mathbf{3}}\right)_{2}{ }^{\mathbf{3 -}}(\mathbf{a q})$ | + |
| :--- | :---: | :---: | :---: | :---: |
| $\mathrm{Br}^{-}(a q)$ |  |  |  |  |
| Initial | - | 1.0 | 0 | 0 |
| Change | - | $-2 S$ | $+S$ | $+S$ |
| Equilibrium | - | $1.0-2 S$ | $S$ | $S$ |

Substituting the values into the expression for $K_{\text {overall }}$ and solving for $S$ :

$$
K_{\text {overall }}=\frac{\left[\mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}\right]\left[\mathrm{Br}^{-}\right]}{\left[\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}\right]^{2}}=\frac{S^{2}}{(1.0 M-2 S)^{2}}=24
$$

Taking the square root of both sides gives

$$
\frac{S}{1.0 M-2 S}=\sqrt{24}=4.9 \quad\left[\mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)_{2}^{3-}\right]=S=0.45 \mathrm{M}
$$

CHECK (a) From the number of ions in the formula of AgBr , we know that $S=\sqrt{K_{\text {sp }}}$, so the order of magnitude seems right: $\sim \sqrt{10^{-14}} \approx 10^{-7}$. (b) The $K_{\text {overall }}$ seems correct: the exponents cancel, and $5 \times 5=25$. Most importantly, the answer makes sense because the photographic process requires the remaining AgBr to be washed off the film and the large $K_{\text {overall }}$ confirms that. We can check $S$ by rounding and working backward to find $K_{\text {overall }}$ : from the reaction table, we find that

$$
\left[\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)^{2-}\right]=1.0 M-2 S=1.0 M-2(0.45 M)=1.0 M-0.90 M=0.1 M
$$

so $K_{\text {overall }} \approx(0.45)^{2} /(0.1)^{2}=20$, within rounding of the calculated value.
FOLLOW-UP PROBLEM 19.14 How does the solubility of AgBr in $1.0 \mathrm{M} \mathrm{NH}_{3}$ compare with its solubility in 1.0 M hypo? $K_{\mathrm{f}}$ of $\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}$is $1.7 \times 10^{7}$.

Developing the image in "hypo."

## Complex Ions of Amphoteric Hydroxides

Many of the same metals that form amphoteric oxides (Chapter 8, p. 327, and Interchapter Topic 4, p. 559) also form slightly soluble amphoteric hydroxides. These compounds dissolve very little in water, but they dissolve to a much greater extent in both acidic and basic solutions. Aluminum hydroxide is one of several examples:

$$
\mathrm{Al}(\mathrm{OH})_{3}(s) \rightleftharpoons \mathrm{Al}^{3+}(a q)+3 \mathrm{OH}^{-}(a q)
$$

It is insoluble in water $\left(K_{\text {sp }}=3 \times 10^{-34}\right)$, but

- It dissolves in acid because $\mathrm{H}_{3} \mathrm{O}^{+}$reacts with the $\mathrm{OH}^{-}$anion (Sample Problem 19.9),

$$
3 \mathrm{H}_{3} \mathrm{O}^{+}(a q)+3 \mathrm{OH}^{-}(a q) \longrightarrow 6 \mathrm{H}_{2} \mathrm{O}(l)
$$

giving the overall equation

$$
\mathrm{Al}(\mathrm{OH})_{3}(s)+3 \mathrm{H}_{3} \mathrm{O}^{+}(a q) \longrightarrow \mathrm{Al}^{3+}(a q)+6 \mathrm{H}_{2} \mathrm{O}(l)
$$

- It dissolves in base through the formation of a complex ion:

$$
\mathrm{Al}(\mathrm{OH})_{3}(s)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{Al}(\mathrm{OH})_{4}^{-}(a q)
$$

Figure 19.16 illustrates this amphoteric behavior but includes some unexpected formulas for the species. Let's see how these species arise. When we dissolve a soluble aluminum salt, such as $\mathrm{Al}\left(\mathrm{NO}_{3}\right)_{3}$, in water and then slowly add a strong base, a white precipitate first forms and then dissolves as more base is added.

What reactions are occurring? The formula for the hydrated $\mathrm{Al}^{3+}$ ion is $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(\mathrm{aq})$. It acts as a weak polyprotic acid and reacts with added $\mathrm{OH}^{-}$ ions in a stepwise manner. In each step, one of the bound $\mathrm{H}_{2} \mathrm{O}$ molecules loses
 is reduced by 1 :

$$
\begin{aligned}
\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q)+\mathrm{OH}^{-}(a q) & \rightleftharpoons \mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{OH}^{2+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \\
\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{OH}^{2+}(a q)+\mathrm{OH}^{-}(a q) & \rightleftharpoons \mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(\mathrm{OH})_{2}^{+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \\
\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(\mathrm{OH})_{2}^{+}(a q)+\mathrm{OH}^{-}(a q) & \rightleftharpoons \mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}(\mathrm{OH})_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
$$

After three protons have been removed from each $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$, the white precipitate has formed, which is the insoluble hydroxide $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}(\mathrm{OH})_{3}(s)$, often written more simply as $\mathrm{Al}(\mathrm{OH})_{3}(s)$. Now you can see that the precipitate actually consists of the hydrated $\mathrm{Al}^{3+}$ ion with an $\mathrm{H}^{+}$removed from each of three bound $\mathrm{H}_{2} \mathrm{O}$ molecules. Addition of $\mathrm{H}_{3} \mathrm{O}^{+}$protonates the $\mathrm{OH}^{-}$ions and re-forms the hydrated $\mathrm{Al}^{3+}$ ion.

Further addition of $\mathrm{OH}^{-}$removes a fourth $\mathrm{H}^{+}$and the precipitate dissolves as the soluble ion $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}(\mathrm{OH})_{4}{ }^{-}(a q)$ forms, which we usually write with the formula $\mathrm{Al}(\mathrm{OH})_{4}{ }^{-}(a q)$ :

$$
\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}(\mathrm{OH})_{3}(s)+\mathrm{OH}^{-}(a q) \rightleftharpoons \mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}(\mathrm{OH})_{4}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

In other words, this complex ion is not created by ligands substituting for bound water molecules but through an acid-base reaction in which added $\mathrm{OH}^{-}$ions titrate bound water molecules.

Several other slightly soluble hydroxides, including those of cadmium, chromium(III), cobalt(III), lead(II), tin(II), and zinc, are amphoteric and exhibit similar reactions:

$$
\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}(\mathrm{OH})_{2}(s)+\mathrm{OH}^{-}(a q) \rightleftharpoons \mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)(\mathrm{OH})_{3}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

In contrast to the preceding hydroxides, the slightly soluble hydroxides of iron(II), iron(III), and calcium dissolve in acid, but do not dissolve in base, because the

## Apago 는

Figure 19.16 The amphoteric behavior of aluminum hydroxide. When solid $\mathrm{Al}(\mathrm{OH})_{3}$ is treated with $\mathrm{H}_{3} \mathrm{O}^{+}$(left) or with $\mathrm{OH}^{-}$(right), it dissolves as a result of the formation of soluble complex ions. The molecular views show that $\mathrm{Al}(\mathrm{OH})_{3}$ is actually the hydrated species

## Hnnancer

$\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}(\mathrm{OH})_{3}$. (The extensive OH bridging that occurs between $\mathrm{Al}^{3+}$ ions throughout the solid is not shown.) Addition of $\mathrm{OH}^{-}$(right) forms the soluble $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}(\mathrm{OH})_{4}{ }^{-}$ion; addition of $\mathrm{H}_{3} \mathrm{O}^{+}$(left) forms the soluble $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$ ion.
three remaining bound water molecules are not acidic enough to lose any of their protons:

$$
\begin{aligned}
\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}(\mathrm{OH})_{3}(s)+3 \mathrm{H}_{3} \mathrm{O}^{+}(a q) & \longrightarrow \mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l) \\
\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}(\mathrm{OH})_{3}(s)+\mathrm{OH}^{-}(a q) & \longrightarrow \text { no reaction }
\end{aligned}
$$

This difference in solubility in base between $\mathrm{Al}(\mathrm{OH})_{3}$ and $\mathrm{Fe}(\mathrm{OH})_{3}$ is the key to an important separation step in the production of aluminum metal, so we'll consider it again in Section 22.4.

## Section Summary

A complex ion consists of a central metal ion covalently bonded to two or more negatively charged or neutral ligands. Its formation is described by a formation constant, $K_{f}$. A hydrated metal ion is a complex ion with water molecules as ligands. Other ligands can displace the water in a stepwise process. In most cases, the $K_{f}$ value of each step is large, so the fully substituted complex ion forms almost completely in the presence of excess ligand. - Adding a solution containing a ligand increases the solubility of an ionic precipitate if the cation forms a complex ion with the ligand. Amphoteric metal hydroxides dissolve in acid and base due to acid-base reactions that form soluble complex ions.

## Chapter Perspective

This chapter is the last of three that explore the nature and variety of equilibrium systems. In Chapter 17, we discussed the central ideas of equilibrium in the context of gaseous systems. In Chapter 18, we extended our understanding to acid-base equilibria. In this chapter, we highlighted three types of aqueous ionic systems and examined their role in the laboratory and the environment. The equilibrium constant, in all its forms, is a number that provides a limit to changes in a system, whether a chemical reaction, a physical change, or the dissolution of a substance. You now have the skills to predict whether a change will take place and to calculate its result, but you still do not know why the change occurs in the first place, or why it stops when it does. In Chapter 20, you'll find out.

## CHAPTER REVIEW GUIDE

The following sections provide many aids to help you study this chapter. (Numbers in parentheses refer to pages, unless noted otherwise.)

## Learning Objectives These are concepts and skills you should know after studying this chapter.

Relevant section and/or sample problem (SP) numbers appear in parentheses.

## Understand These Concepts

1. How the presence of a common ion suppresses a reaction that forms it (Section 19.1)
2. Why the concentrations of buffer components must be high to minimize the change in pH from addition of smathey $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$(Section 19.1)
3. How buffer capacity depends on buffer concentration and on the $\mathrm{p} K_{\mathrm{a}}$ of the acid component; why buffer range is within $\pm 1 \mathrm{pH}$ unit of the $\mathrm{p} K_{\mathrm{a}}$ (Section 19.1)
4. The nature of an acid-base indicator as a conjugate acid-base pair with differently colored acidic and basic forms (Section 19.2)
5. The distinction between equivalence point and end point in an acid-base titration (Section 19.2)
6. Why the shapes of strong acid-strong base, weak acidstrong base, and strong acid-weak base titration curves differ (Section 19.2)
7. How the pH at the equivalence point is determined by the species present; why the pH at the midpoint of the buffer region equals the $\mathrm{p} K_{\mathrm{a}}$ of the acid (Section 19.2)
8. How the titration curve of a polyprotic acid has a buffer region and equivalence point for each ionizable proton (Section 19.2)
9. How a slightly soluble ionic compound reaches equilibrium in water, expressed by an equilibrium (solubility-product) constant, $K_{\text {sp }}$ (Section 19.3)
10. Why incomplete dissociation of an ionic compound leads to approximate calculated values for $K_{\text {sp }}$ and solubility (Section 19.3)
11. Why a common ion in a solution decreases the solubility of its compounds (Section 19.3)
12. How pH affects the solubility of a compound that contains a weak-acid anion (Section 19.3)
13. How precipitate formation depends on the relative values of $Q_{\text {sp }}$ and $K_{\text {sp }}$ (Section 19.3)
14. How selective precipitation and simultaneous equilibria are used to separate ions (Section 19.3)
15. How complex-ion formation is stepwise and expressed by an overall equilibrium (formation) constant, $K_{\mathrm{f}}$ (Section 19.4)
16. Why addition of a ligand increases the solubility of a compound whose metal ion forms a complex ion (Section 19.4)
17. How the aqueous chemistry of amphoteric hydroxides involves precipitation, complex-ion formation, and acid-base equilibria (Section 19.4)

## MasterTheseSkfts エ

1. Using stoichiometry and equilibrium problem-solving techniques to calculate the effect of added $\mathrm{H}_{3} \mathrm{O}^{+}$or $\mathrm{OH}^{-}$on buffer pH (SP 19.1)
2. Using the Henderson-Hasselbalch equation to calculate buffer pH (Section 19.1)
3. Using molecular scenes to depict buffer capacity (SP 19.2)
4. Choosing the components of a buffer with a given pH and calculating their quantities (SP 19.3)
5. Calculating the pH at any point in an acid-base titration (Section 19.2 and SP 19.4)
6. Choosing an appropriate indicator based on the pH at various points in a titration (Section 19.2)
7. Writing $K_{\text {sp }}$ expressions for slightly soluble ionic compounds (SP 19.5)
8. Using $K_{\text {sp }}$ values to compare solubilities for compounds with the same total number of ions (Section 19.3)
9. Calculating a $K_{\text {sp }}$ value from solubility data (SP 19.6)
10. Calculating solubility from a $K_{\text {sp }}$ value (SP 19.7)
11. Calculating the decrease in solubility caused by the presence of a common ion (SP 19.8)
12. Predicting the effect of added $\mathrm{H}_{3} \mathrm{O}^{+}$on solubility (SP 19.9)
13. Using ion concentrations to calculate $Q_{\mathrm{sp}}$ and compare it with $K_{\text {sp }}$ to predict whether a precipitate forms (SPs 19.10, 19.11)
14. Comparing $K_{\mathrm{sp}}$ values in order to separate ions by selective precipitation (SP 19.12)
15. Calculating the concentration of metal ion remaining after addition of excess ligand forms a complex ion (SP 19.13)
16. Using an overall equilibrium constant ( $K_{\text {sp }} \times K_{\mathrm{f}}$ ) to calculate the effect of complex-ion formation on solubility (SP 19.14)

Key Terms These important terms appear in boldface in the chapter and are defined again in the Glossary.

## Section 19.1

acid-base buffer (832)
common-ion effect (833)
Henderson-Hasselbalch equation (837)
buffer capacity (838) buffer range (838)

## Section 19.2

acid-base titration curve (841) equivalence point (843) end point (844)

## Section 19.3

solubility-product constant ( $K_{\text {sp }}$ ) (852)
molar solubility (853)
selective precipitation (861)

## Section 19.4

complex ion (862)
ligand (862)
formation constant $\left(K_{\mathrm{f}}\right)$ (865)

Key Equations and Relationships Numbered and screened concepts are listed for you to refer to or memorize.
19.1 Finding the pH from known concentrations of a conjugate acid-base pair (Henderson-Hasselbalch equation) (837):

$$
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{[\text { base }]}{[\text { acid }]}\right)
$$

19.2 Defining the equilibrium condition for a saturated solution of a slightly soluble compound, $\mathrm{M}_{p} \mathrm{X}_{q}$, composed of $\mathrm{M}^{n+}$ and $\mathrm{X}^{z^{-}}$ions (852):

$$
Q_{\mathrm{sp}}=\left[\mathrm{M}^{n+}\right]^{p}\left[\mathrm{X}^{z-}\right]^{q}=K_{\mathrm{sp}}
$$

Highlighted Figures and Tables These figures (F) and tables (T) provide a visual review of key ideas.

F19.3 How a buffer works (834)
F19.4 Buffer capacity and pH change (838)
F19.5 Colors and pH ranges of acid-base indicators (842)

F19.7 A strong acid-strong base titration curve (843)
F19.8 A weak acid-strong base titration curve (845)
F19.9 A weak base-strong acid titration curve (849)

Brief Solutions to FOLLOW-UP PROBLEMS Compare your solutions to these calculation steps and answers.
19.1 (a) Before addition:

Assuming $x$ is small enough to be neglected,
$[\mathrm{HF}]=0.50 \mathrm{M}$ and $\left[\mathrm{F}^{-}\right]=0.45 \mathrm{M}$
$\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=K_{\mathrm{a}} \times \frac{[\mathrm{HF}]}{\left[\mathrm{F}^{-}\right]} \approx\left(6.8 \times 10^{-4}\right)\left(\frac{0.50}{0.45}\right)=7.6 \times 10^{-4} M$

$$
\mathrm{pH}=3.12
$$

(b) After addition of 0.40 g of $\mathrm{NaOH}(0.010 \mathrm{~mol}$ of NaOH$)$ to 1.0 L of buffer,
$[\mathrm{HF}]=0.49 \mathrm{M}$ and $\left[\mathrm{F}^{-}\right]=0.46 \mathrm{M}$
$\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \approx\left(6.8 \times 10^{-4}\right)\left(\frac{0.49}{0.46}\right)=7.2 \times 10^{-4} \mathrm{M} ; \mathrm{pH}=3.14$
19.2 (a) Strong base would convert HB to $\mathrm{B}^{-}$, thereby making the ratio closer to 1 .
(b)

$19.3\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-\mathrm{pH}}=10^{-4.25}=5.6 \times 10^{-5}$

$$
\begin{aligned}
{\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}\right] } & =\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COO}^{-}\right]}{K_{\mathrm{a}}} \\
& =\frac{\left(5.6 \times 10^{-5}\right)(0.050)}{6.3 \times 10^{-5}}=0.044 \mathrm{M}
\end{aligned}
$$

Mass (g) of $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}$

$$
\begin{aligned}
= & 5.0 \mathrm{~L} \text { soln } \times \frac{0.044 \mathrm{~mol} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}}{1 \mathrm{~L} \text { soln }} \\
& \times \frac{122.12 \mathrm{~g} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}}{1 \mathrm{~mol} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}} \\
= & 27 \mathrm{~g} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}
\end{aligned}
$$

Dissolve 27 g of $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}$ in 4.9 L of $0.050 \mathrm{M} \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COONa}$ and add solution to make 5.0 L . Adjust pH to 4.25 with strong acid or base.

$$
\begin{aligned}
& 19.4 \text { (a) }\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \approx \sqrt{\left(2.3 \times 10^{-9}\right)(0.2000)}=2.1 \times 10^{-5} \mathrm{M} \\
& \mathrm{pH}=4.68 \\
& \text { (b) }\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=K_{\mathrm{a}} \times \frac{[\mathrm{HBrO}]}{\left[\mathrm{BrO}^{-}\right]}=\left(2.3 \times 10^{-9}\right)(1)=2.3 \times 10^{-9} \mathrm{M} \\
& \mathrm{pH}=8.64 \\
& \text { (c) }\left[\mathrm{BrO}^{-}\right]=\frac{\text { moles of } \mathrm{BrO}^{-}}{\text {total volume }}=\frac{0.004000 \mathrm{~mol}}{0.06000 \mathrm{~L}}=0.06667 \mathrm{M} \\
& K_{\mathrm{b}} \text { of } \mathrm{BrO}^{-}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}} \text { of } \mathrm{HBrO}}=4.3 \times 10^{-6} \\
& {\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\frac{K_{\mathrm{w}}}{\sqrt{K_{\mathrm{b}} \times\left[\mathrm{BrO}^{-}\right]}}} \\
& \approx \frac{1.0 \times 10^{-14}}{\sqrt{\left(4.3 \times 10^{-6}\right)(0.06667)}}=1.9 \times 10^{-11} \mathrm{M} \\
& \mathrm{pH}=10.72 \\
& \text { (d) Moles of } \mathrm{OH}^{-} \text {added }=0.008000 \mathrm{~mol} \\
& \text { Volume (L) of } \mathrm{OH}^{-} \text {soln }=0.08000 \mathrm{~L} \\
& {\left[\mathrm{OH}^{-}\right]=\frac{\text { moles of } \mathrm{OH}^{-} \text {unreacted }}{\text { total volume }}} \\
& =\frac{0.008000 \mathrm{~mol}-0.004000 \mathrm{~mol}}{(0.02000+0.08000) \mathrm{L}}=0.04000 \mathrm{M} \\
& {\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\frac{K_{\mathrm{w}}}{\left[\mathrm{OH}^{-}\right]}=2.5 \times 10^{-13}} \\
& \mathrm{pH}=12.60
\end{aligned}
$$

## Brief Solutions to FOLLOW-UP PROBLEMS (continued)

19.5 (a) $K_{\text {sp }}=\left[\mathrm{Ca}^{2+}\right]\left[\mathrm{SO}_{4}{ }^{2-}\right]$
(b) $K_{\text {sp }}=\left[\mathrm{Cr}^{3+}\right]^{2}\left[\mathrm{CO}_{3}{ }^{2-}\right]^{3}$
(c) $K_{\text {sp }}=\left[\mathrm{Mg}^{2+}\right]\left[\mathrm{OH}^{-}\right]^{2}$
(d) $K_{\mathrm{sp}}=\left[\mathrm{As}^{3+}\right]^{2}\left[\mathrm{HS}^{-}\right]^{3}\left[\mathrm{OH}^{-}\right]^{3}$
$19.6\left[\mathrm{CaF}_{2}\right]=\frac{1.5 \times 10^{-4} \mathrm{~g} \mathrm{CaF}_{2}}{10.0 \mathrm{~mL} \text { soln }} \times \frac{1000 \mathrm{~mL}}{1 \mathrm{~L}} \times \frac{1 \mathrm{~mol} \mathrm{CaF}_{2}}{78.08 \mathrm{~g} \mathrm{CaF}_{2}}$

$$
=1.9 \times 10^{-4} \mathrm{M}
$$

$\mathrm{CaF}_{2}(s) \rightleftharpoons \mathrm{Ca}^{2+}(a q)+2 \mathrm{~F}^{-}(a q)$
$\left[\mathrm{Ca}^{2+}\right]=1.9 \times 10^{-4} M$ and $\left[\mathrm{F}^{-}\right]=3.8 \times 10^{-4} M$
$K_{\mathrm{sp}}=\left[\mathrm{Ca}^{2+}\right]\left[\mathrm{F}^{-}\right]^{2}=\left(1.9 \times 10^{-4}\right)\left(3.8 \times 10^{-4}\right)^{2}=2.7 \times 10^{-11}$
19.7 From the reaction table, $\left[\mathrm{Mg}^{2+}\right]=S$ and $\left[\mathrm{OH}^{-}\right]=2 S$ $K_{\text {sp }}=\left[\mathrm{Mg}^{2+}\right]\left[\mathrm{OH}^{-}\right]^{2}=4 S^{3}=6.3 \times 10^{-10} ; S=5.4 \times 10^{-4} \mathrm{M}$
19.8 (a) In water: $K_{\mathrm{sp}}=\left[\mathrm{Ba}^{2+}\right]\left[\mathrm{SO}_{4}{ }^{2-}\right]=S^{2}=1.1 \times 10^{-10}$; $S=1.0 \times 10^{-5}$
(b) In $0.10 \mathrm{Ma}_{2} \mathrm{SO}_{4}:\left[\mathrm{SO}_{4}{ }^{2-}\right]=0.10 \mathrm{M}$
$K_{\text {sp }}=1.1 \times 10^{-10} \approx S \times 0.10 ; S=1.1 \times 10^{-9} M$
$S$ decreases in presence of the common ion $\mathrm{SO}_{4}{ }^{2-}$.
19.9 (a) Increases solubility.

$$
\begin{aligned}
\mathrm{CaF}_{2}(s) & \rightleftharpoons \mathrm{Ca}^{2+}(a q)+2 \mathrm{~F}^{-}(a q) \\
\mathrm{F}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) & \longrightarrow \mathrm{HF}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
$$

(b) Increases solubility.

$$
\mathrm{ZnS}(s)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{Zn}^{2+}(a q)+\mathrm{HS}^{-}(a q)+\mathrm{OH}^{-}(a q)
$$

$\mathrm{HS}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{~S}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$
$\mathrm{OH}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)$
(c) No effect. $\mathrm{I}^{-}(a q)$ is the conjugate base of strong acid HI .
$19.10 \mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s) \rightleftharpoons 3 \mathrm{Ca}^{2+}(a q)+2 \mathrm{PO}_{4}{ }^{3-}(a q)$
$Q_{\text {sp }}=\left[\mathrm{Ca}^{2+}\right]^{3}\left[\mathrm{PO}_{4}{ }^{3-}\right]^{2}=\left(1.0 \times 10^{-9}\right)^{5}=1.0 \times 10^{-45}$
$Q_{\mathrm{sp}}<K_{\mathrm{sp}}$, so $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ will not precipitate.
19.11 (a) Scene 3 has the same relative numbers of ions as in the formula. (b) Based on $\mathrm{Ni}(\mathrm{OH})_{2}(s) \rightleftharpoons \mathrm{Ni}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)$ and $Q_{\mathrm{sp}}=\left[\mathrm{Ni}^{2+}\right]\left[\mathrm{OH}^{-}\right]^{2}$, the ion products are $(3)(4)^{2}=48$ in scene 1; (4) $(2)^{2}=16$ in scene 2 ; and $(2)(4)^{2}=32=K_{\text {sp }}$ in scene 3 . $Q_{\text {sp }}$ of scene 1 exceeds $K_{\text {sp }}$ of scene 3. (c) Addition of acid will decrease mass of $\mathrm{Ni}(\mathrm{OH})_{2}(s)$ by reacting with $\mathrm{OH}^{-}$, thereby causing more solid to dissolve; addition of base will increase mass of $\mathrm{Ni}(\mathrm{OH})_{2}(s)$ due to common-ion effect.
19.12 Both are $1 / 1$ salts, and $K_{\text {sp }}$ values show $\mathrm{CaSO}_{4}$ is more soluble:
$\left[\mathrm{SO}_{4}{ }^{2-}\right]=\frac{K_{\mathrm{sp}}}{\left[\mathrm{Ca}^{2+}\right]}=\frac{2.4 \times 10^{-5}}{(0.025)(0.9999)}=9.6 \times 10^{-4} \mathrm{M}$
$19.13\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\right]_{\text {init }}=\frac{(0.0255 \mathrm{~L})\left(3.1 \times 10^{-2} \mathrm{M}\right)}{0.0255 \mathrm{~L}+0.0350 \mathrm{~L}}$

$$
=1.3 \times 10^{-2} \mathrm{M}
$$

Similarly, $\left[\mathrm{CN}^{-}\right]_{\text {init }}=0.87 \mathrm{M}$. From the reaction table,

$$
\begin{aligned}
& K_{\mathrm{f}}=\frac{\left[\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}\right]}{\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\right]\left[\mathrm{CN}^{-}\right]^{6}}=4.0 \times 10^{43} \approx \frac{1.3 \times 10^{-2}}{x(0.79)^{6}} \\
& x=\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}\right] \approx 1.3 \times 10^{-45} \\
& \begin{array}{l}
19.14 \mathrm{AgBr}(s)+2 \mathrm{NH}_{3}(a q) \rightleftharpoons \\
K_{\text {overall }} \\
=K_{\text {sp }} \text { of } \mathrm{AgBr}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q)+K_{\mathrm{f}} \text { of } \mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{-}(a q) \\
\\
\quad=8.5 \times 10^{-6}
\end{array}
\end{aligned}
$$

From the reaction table, $\frac{S}{1.0-2 S}=\sqrt{8.5 \times 10^{-6}}=2.9 \times 10^{-3}$

$$
S=\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}\right]=2.9 \times 10^{-3} \mathrm{M}
$$

Solubility is greater in 1.0 M hypo than in $1.0 \mathrm{M} \mathrm{NH}_{3}$.

## PROBLEMS

Problems with colored numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and provide the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.
Note: Unless stated otherwise, all of the problems for this chapter refer to aqueous solutions at $298 \mathrm{~K}\left(25^{\circ} \mathrm{C}\right)$.

## Equilibria of Acid-Base Buffer Systems <br> (Sample Problems 19.1 to 19.3)

## - Concept Review Questions

19.1 What is the purpose of an acid-base buffer?
19.2 How do the acid and base components of a buffer function?

Why are they often a conjugate acid-base pair of a weak acid?
19.3 What is the common-ion effect? How is it related to Le Châtelier's principle? Explain with equations that include HF and NaF .
19.4 The scenes below depict solutions of the same HA/A ${ }^{-}$buffer (with counterions and water molecules omitted for clarity). (a) Which solution has the greatest buffer capacity? (b) Explain how the pH ranges of the buffers compare. (c) Which solution can react with the largest amount of added strong acid?

19.5 What is the difference between buffers with high and low capacities? Will adding 0.01 mol of HCl produce a greater pH change in a buffer with a high or a low capacity? Explain.
19.6 Which of these factors influence buffer capacity? How?
(a) Conjugate acid-base pair
(b) pH of the buffer
(c) Concentration of buffer components
(d) Buffer range
(e) $\mathrm{p} K_{\mathrm{a}}$ of the acid component
19.7 What is the relationship between the buffer range and the buffer-component concentration ratio?
19.8 A chemist needs a pH 3.5 buffer. Should she use NaOH with formic acid ( $K_{\mathrm{a}}=1.8 \times 10^{-4}$ ) or with acetic acid ( $K_{\mathrm{a}}=$ $\left.1.8 \times 10^{-5}\right)$ ? Why? What is the disadvantage of choosing the other acid? What is the role of the NaOH ?
19.9 State and explain the relative change in the pH and in the buffer-component concentration ratio, [NaA]/[HA], for each of the following additions:
(a) Add 0.1 M NaOH to the buffer
(b) Add 0.1 M HCl to the buffer
(c) Dissolve pure NaA in the buffer
(d) Dissolve pure HA in the buffer
19.10 Does the pH increase or decrease, and does it do so to a large or small extent, with each of the following additions?
(a) 5 drops of 0.1 M NaOH to 100 mL of 0.5 M acetate buffer
(b) 5 drops of 0.1 M HCl to 100 mL of 0.5 M acetate buffer
(c) 5 drops of 0.1 M NaOH to 100 mL of 0.5 M HCl
(d) 5 drops of 0.1 M NaOH to distilled water

## Skill-Building Exercises (grouped in similar pairs)

19.11 What are the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and the pH of a propanoic acidpropanoate buffer that consists of $0.35 \mathrm{M} \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{COONa}$ and $0.15 \mathrm{M} \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{COOH}$ ( $K_{\mathrm{a}}$ of propanoic acid $=1.3 \times 10^{-5}$ )?
19.12 What are the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and the pH of a benzoic acid-benzoate buffer that consists of 0.33 M C/H5OOH and I0. 28 EM $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COONa}\left(K_{\mathrm{a}}\right.$ of benzoic acid $=6.3 \times 10^{-5}$ ) ?
19.13 What are the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and the pH of a buffer that consists of $0.55 M \mathrm{HNO}_{2}$ and $0.75 \mathrm{M} \mathrm{NO}_{2}\left(K_{\mathrm{a}}\right.$ of $\left.\mathrm{HNO}_{2}=7.1 \times 10^{-4}\right)$ ?
19.14 What are the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and the pH of a buffer that consists of $0.20 M \mathrm{HF}$ and $0.25 M \mathrm{KF}\left(K_{\mathrm{a}}\right.$ of $\left.\mathrm{HF}=6.8 \times 10^{-4}\right)$ ?
19.15 Find the pH of a buffer that consists of 0.45 M HCOOH and $0.63 M$ HCOONa ( $\mathrm{p} K_{\mathrm{a}}$ of $\mathrm{HCOOH}=3.74$ ).
19.16 Find the pH of a buffer that consists of 0.95 M HBrO and $0.68 \mathrm{M} \mathrm{KBrO}\left(\mathrm{p} K_{\mathrm{a}}\right.$ of $\left.\mathrm{HBrO}=8.64\right)$.
19.17 Find the pH of a buffer that consists of 1.3 M sodium phenolate $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{ONa}\right)$ and 1.2 M phenol $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}\right)\left(\mathrm{p} K_{\mathrm{a}}\right.$ of phenol $=10.00$ ).
19.18 Find the pH of a buffer that consists of 0.12 M boric acid $\left(\mathrm{H}_{3} \mathrm{BO}_{3}\right)$ and 0.82 M sodium borate $\left(\mathrm{NaH}_{2} \mathrm{BO}_{3}\right)\left(\mathrm{p} K_{\mathrm{a}}\right.$ of boric acid $=9.24$ ).
19.19 Find the pH of a buffer that consists of $0.25 \mathrm{M} \mathrm{NH}_{3}$ and $0.15 \mathrm{M} \mathrm{H}_{4} \mathrm{Cl}\left(\mathrm{p} K_{\mathrm{b}}\right.$ of $\left.\mathrm{NH}_{3}=4.75\right)$.
19.20 Find the pH of a buffer that consists of 0.50 M methylamine $\left(\mathrm{CH}_{3} \mathrm{NH}_{2}\right)$ and $0.60 \mathrm{M} \mathrm{CH}_{3} \mathrm{NH}_{3} \mathrm{Cl}\left(\mathrm{p} K_{\mathrm{b}}\right.$ of $\left.\mathrm{CH}_{3} \mathrm{NH}_{2}=3.35\right)$.
19.21 A buffer consists of $0.22 \mathrm{M} \mathrm{KHCO}_{3}$ and $0.37 \mathrm{M}_{2} \mathrm{CO}_{3}$. Carbonic acid is a diprotic acid with $K_{\mathrm{a} 1}=4.5 \times 10^{-7}$ and $K_{\mathrm{a} 2}=$ $4.7 \times 10^{-11}$. (a) Which $K_{\mathrm{a}}$ value is more important to this buffer? (b) What is the buffer pH ?
19.22 A buffer consists of $0.50 \mathrm{M} \mathrm{NaH}{ }_{2} \mathrm{PO}_{4}$ and $0.40 \mathrm{Ma}_{2} \mathrm{HPO}_{4}$. Phosphoric acid is a triprotic acid $\left(K_{\mathrm{a} 1}=7.2 \times 10^{-3}, K_{\mathrm{a} 2}=\right.$ $6.3 \times 10^{-8}$, and $K_{\mathrm{a} 3}=4.2 \times 10^{-13}$ ). (a) Which $K_{\mathrm{a}}$ value is most important to this buffer? (b) What is the buffer pH ?
19.23 What is the component concentration ratio, $\left[\mathrm{Pr}^{-}\right] /[\mathrm{HPr}]$, of a buffer that has a pH of $5.44\left(K_{\mathrm{a}}\right.$ of $\left.\mathrm{HPr}=1.3 \times 10^{-5}\right)$ ?
19.24 What is the component concentration ratio, $\left[\mathrm{NO}_{2}{ }^{-}\right] /\left[\mathrm{HNO}_{2}\right]$, of a buffer that has a pH of $2.95\left(K_{\mathrm{a}}\right.$ of $\left.\mathrm{HNO}_{2}=7.1 \times 10^{-4}\right)$ ?
19.25 What is the component concentration ratio, $\left[\mathrm{BrO}^{-}\right] /[\mathrm{HBrO}]$, of a buffer that has a pH of $7.95\left(K_{\mathrm{a}}\right.$ of $\left.\mathrm{HBrO}=2.3 \times 10^{-9}\right)$ ?
19.26 What is the component concentration ratio, $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}\right] /\left[\mathrm{CH}_{3} \mathrm{COOH}\right]$, of a buffer that has a pH of 4.39 $\left(K_{\mathrm{a}}\right.$ of $\left.\mathrm{CH}_{3} \mathrm{COOH}=1.8 \times 10^{-5}\right)$ ?
19.27 A buffer containing 0.2000 M of acid, HA, and 0.1500 M of its conjugate base, $\mathrm{A}^{-}$, has a pH of 3.35 . What is the pH after 0.0015 mol of NaOH is added to 0.5000 L of this solution?
19.28 A buffer that contains $0.40 M$ base, B, and $0.25 M$ of its conjugate acid, $\mathrm{BH}^{+}$, has a pH of 8.88 . What is the pH after 0.0020 mol of HCl is added to 0.25 L of this solution?
19.29 A buffer that contains 0.110 MHY and $0.220 \mathrm{M}^{-}$has a pH of 8.77 . What is the pH after 0.0015 mol of $\mathrm{Ba}(\mathrm{OH})_{2}$ is added to 0.350 L of this solution?
19.30 A buffer that contains 1.05 MB and $0.750 \mathrm{M} \mathrm{BH}+$ has a pH of 9.50 . What is the pH after 0.0050 mol of HCl is added to 0.500 L of this solution?
19.31 A buffer is prepared by mixing 204 mL of 0.452 M HCl and 0.500 L of $0.400 M$ sodium acetate. (See Appendix C.) (a) What is the pH ? (b) How many grams of KOH must be added to 0.500 L of the buffer to change the pH by 0.15 units?
19.32 A buffer is prepared by mixing 50.0 mL of 0.050 M sodium bicarbonate and 10.7 mL of 0.10 M NaOH . (See Appendix C.) EIf Whatis the ${ }^{\text {PH}}$ ? (b) How many grams of HCl must be added to 25.0 mL of the buffer to change the pH by 0.07 units?
19.33 Choose specific acid-base conjugate pairs to make the following buffers: (a) $\mathrm{pH} \approx 4.5$; (b) $\mathrm{pH} \approx 7.0$. (See Appendix C.) 19.34 Choose specific acid-base conjugate pairs to make the following buffers: (a) $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \approx 1 \times 10^{-9} M$; (b) $\left[\mathrm{OH}^{-}\right] \approx 3 \times 10^{-5}$ M. (See Appendix C.)
19.35 Choose specific acid-base conjugate pairs to make the following buffers: (a) $\mathrm{pH} \approx 3.5$; (b) $\mathrm{pH} \approx 5.5$. (See Appendix C.) 19.36 Choose specific acid-base conjugate pairs to make the following buffers: (a) $\left[\mathrm{OH}^{-}\right] \approx 1 \times 10^{-6} M$; (b) $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right] \approx$ $4 \times 10^{-4} M$. (See Appendix C.)

## - Problems in Context

19.37 An industrial chemist studying bleaching and sterilizing prepares several hypochlorite buffers. Find the pH of (a) 0.100 M HClO and 0.100 M NaClO ; (b) 0.100 M HClO and 0.150 M NaClO ; (c) $0.150 M \mathrm{HClO}$ and 0.100 M NaClO ; (d) 1.0 L of the solution in part (a) after 0.0050 mol of NaOH has been added.
19.38 Oxoanions of phosphorus are buffer components in blood. For a $\mathrm{KH}_{2} \mathrm{PO}_{4} / \mathrm{Na}_{2} \mathrm{HPO}_{4}$ solution with $\mathrm{pH}=7.40(\mathrm{pH}$ of normal arterial blood), what is the buffer-component concentration ratio?

## Acid-Base Titration Curves

(Sample Problem 19.4)

## - Concept Review Questions

19.39 How can you estimate the pH range of an indicator's color change? Why do some indicators have two separate pH ranges? 19.40 Why does the color change of an indicator take place over a range of about 2 pH units?
19.41 Why doesn't the addition of an acid-base indicator affect the pH of the test solution?
19.42 What is the difference between the end point of a titration and the equivalence point? Is the equivalence point always reached first? Explain.
19.43 The scenes below depict the relative concentrations of $\mathrm{H}_{3} \mathrm{PO}_{4}, \mathrm{H}_{2} \mathrm{PO}_{4}^{-}$, and $\mathrm{HPO}_{4}^{2-}$ during a titration with aqueous NaOH , but they are out of order. (Phosphate groups are purple, hydrogens are blue, and $\mathrm{Na}^{+}$ions and water molecules are not shown.) (a) List the scenes in the correct order. (b) What is the pH in the correctly ordered second scene (see Appendix C)? (c) If it requires 10.00 mL of the NaOH solution to reach this scene, how much more is needed to reach the last scene?

19.44 Explain how strong acid-strong base, weak acid-strong base, and weak base-strong acid titrations using the same concentrations differ in terms of (a) the initial pH and (b) the pH at the equivalence point. (The component in italics is in the flask.)
19.45 What species are in the buffer region of a weak acid-strong base titration? How are they different from the species at the equivalence point? How are they different from the species in the buffer region of a weak base-strong acidtilionyo PD 19.46 Why is the center of the buffer region of a weak acid-strong base titration significant?
19.47 How does the titration curve of a monoprotic acid differ from that of a diprotic acid?

Skill-Building Exercises (grouped in similar pairs)
19.48 The indicator cresol red has $K_{\mathrm{a}}=3.5 \times 10^{-9}$. Over what approximate pH range does it change color?
19.49 The indicator ethyl red has $K_{\mathrm{a}}=3.8 \times 10^{-6}$. Over what approximate pH range does it change color?
19.50 Use Figure 19.5 to find an indicator for these titrations:
(a) 0.10 M HCl with 0.10 M NaOH
(b) 0.10 M HCOOH (Appendix C) with 0.10 M NaOH
19.51 Use Figure 19.5 to find an indicator for these titrations:
(a) $0.10 \mathrm{M} \mathrm{CH}_{3} \mathrm{NH}_{2}$ (Appendix C) with 0.10 M HCl
(b) 0.50 M HI with 0.10 M KOH
19.52 Use Figure 19.5 to find an indicator for these titrations:
(a) $0.5 \mathrm{M}\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}$ (Appendix C) with 0.5 M HBr
(b) 0.2 M KOH with $0.2 \mathrm{M} \mathrm{HNO}_{3}$
19.53 Use Figure 19.5 to find an indicator for these titrations:
(a) $0.25 \mathrm{M}_{6} \mathrm{H}_{5} \mathrm{COOH}$ (Appendix C) with 0.25 M KOH
(b) $0.50 \mathrm{M} \mathrm{NH}_{4} \mathrm{Cl}$ (Appendix C) with 0.50 M NaOH
19.54 Calculate the pH during the titration of 40.00 mL of 0.1000 M HCl with 0.1000 M NaOH solution after the following additions of base:
(a) 0 mL
(b) 25.00 mL
(c) 39.00 mL
(d) 39.90 mL
19.55 Calculate the pH during the titration of 30.00 mL of 0.1000 M KOH with 0.1000 M HBr solution after the following additions of acid:
(a) 0 mL
(b) 15.00 mL
(c) 29.00 mL
(d) 29.90 mL
(e) 30.00 mL
(f) 30.10 mL
(g) 40.00 mL
19.56 Find the pH during the titration of 20.00 mL of 0.1000 M butanoic acid, $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{COOH}\left(K_{\mathrm{a}}=1.54 \times 10^{-5}\right)$, with 0.1000 M NaOH solution after the following additions of titrant:
(a) 0 mL
(b) 10.00 mL
(c) 15.00 mL
(d) 19.00 mL
(e) 19.95 mL
(f) 20.00 mL
(g) 20.05 mL
(h) 25.00 mL
19.57 Find the pH during the titration of 20.00 mL of 0.1000 M triethylamine, $\left(\mathrm{CH}_{3} \mathrm{CH}_{2}\right)_{3} \mathrm{~N}\left(K_{\mathrm{b}}=5.2 \times 10^{-4}\right)$, with 0.1000 M HCl solution after the following additions of titrant:
(a) 0 mL
(b) 10.00 mL
(c) 15.00 mL
(d) 19.00 mL
(e) 19.95 mL
(f) 20.00 mL
(g) 20.05 mL
(h) 25.00 mL
19.58 Find the pH of the equivalence point(s) and the volume $(\mathrm{mL})$ of 0.0372 M NaOH needed to reach it in titrations of
(a) 42.2 mL of $0.0520 \mathrm{M} \mathrm{CH}_{3} \mathrm{COOH}$
(b) 28.9 mL of $0.0850 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{3}$ (two equivalence points)
19.59 Find the pH of the equivalence point(s) and the volume $(\mathrm{mL})$ of 0.0588 M KOH needed to reach it in titrations of
(a) 23.4 mL of $0.0390 \mathrm{M} \mathrm{HNO}_{2}$
(b) 17.3 mL of $0.130 \mathrm{M} \mathrm{H}_{2} \mathrm{CO}_{3}$ (two equivalence points)
19.60 Find the pH of the equivalence point(s) and the volume $(\mathrm{mL})$ of 0.125 M HCl needed to reach it in titrations of
(a) 65.5 mL of $0.234 \mathrm{M} \mathrm{NH}_{3}$
(b) 21.8 mL of $1.11 \mathrm{M} \mathrm{CH}_{3} \mathrm{NH}_{2}$
 reach the equivalence point(s) in titrations of
(a) 2.65 L of 0.0750 M pyridine $\left(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\right)$
(b) 0.188 L of 0.250 M ethylenediamine $\left(\mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\right)$

## Equilibria of Slightly Soluble Ionic Compounds

(Sample Problems 19.5 to 19.12)

## - Concept Review Questions

19.62 The molar solubility of $\mathrm{M}_{2} \mathrm{X}$ is $5 \times 10^{-5} \mathrm{M}$. What is the molarity of each ion? How do you set up the calculation to find $K_{\text {sp }}$ ? What assumption must you make about the dissociation of $\mathrm{M}_{2} \mathrm{X}$ into ions? Why is the calculated $K_{\text {sp }}$ higher than the actual value?
19.63 Why does pH affect the solubility of $\mathrm{BaF}_{2}$ but not of $\mathrm{BaCl}_{2}$ ?
19.64 A list of $K_{\text {sp }}$ values like that in Appendix C can be used to compare the solubility of silver chloride directly with that of silver bromide but not with that of silver chromate. Explain.
19.65 In a gaseous equilibrium, the reverse reaction occurs when $Q_{\mathrm{c}}>K_{\mathrm{c}}$. What occurs in aqueous solution when $Q_{\mathrm{sp}}>K_{\mathrm{sp}}$ ?

## - Skill-Building Exercises (grouped in similar pairs)

19.66 Write the ion-product expressions for (a) silver carbonate;
(b) barium fluoride; (c) copper(II) sulfide.
19.67 Write the ion-product expressions for (a) iron(III) hydroxide; (b) barium phosphate; (c) tin(II) sulfide.
19.68 Write the ion-product expressions for (a) calcium chromate; (b) silver cyanide; (c) nickel(II) sulfide.
19.69 Write the ion-product expressions for (a) lead(II) iodide; (b) strontium sulfate; (c) cadmium sulfide.
19.70 The solubility of silver carbonate is 0.032 M at $20^{\circ} \mathrm{C}$. Calculate its $K_{\mathrm{sp}}$.
19.71 The solubility of zinc oxalate is $7.9 \times 10^{-3} M$ at $18^{\circ} \mathrm{C}$. Calculate its $K_{\text {sp }}$.
19.72 The solubility of silver dichromate at $15^{\circ} \mathrm{C}$ is $8.3 \times 10^{-3} \mathrm{~g} / 100 \mathrm{~mL}$ solution. Calculate its $K_{\mathrm{sp}}$.
19.73 The solubility of calcium sulfate at $30^{\circ} \mathrm{C}$ is $0.209 \mathrm{~g} / 100 \mathrm{~mL}$ solution. Calculate its $K_{\mathrm{sp}}$.
19.74 Find the molar solubility of $\mathrm{SrCO}_{3}\left(K_{\text {sp }}=5.4 \times 10^{-10}\right)$ in
(a) pure water and (b) $0.13 \mathrm{M} \mathrm{Sr}\left(\mathrm{NO}_{3}\right)_{2}$.
19.75 Find the molar solubility of $\mathrm{BaCrO}_{4}\left(K_{\text {sp }}=2.1 \times 10^{-10}\right)$ in (a) pure water and (b) $1.5 \times 10^{-3} M \mathrm{Na}_{2} \mathrm{CrO}_{4}$.
19.76 Calculate the molar solubility of $\mathrm{Ca}\left(\mathrm{IO}_{3}\right)_{2}$ in (a) 0.060 M $\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}$ and (b) 0.060 M NaIO . (See Appendix C.)
19.77 Calculate the molar solubility of $\mathrm{Ag}_{2} \mathrm{SO}_{4}$ in (a) 0.22 M $\mathrm{AgNO}_{3}$ and (b) $0.22 \mathrm{M} \mathrm{Na}_{2} \mathrm{SO}_{4}$. (See Appendix C.)
19.78 Which compound in each pair is more soluble in water?
(a) Magnesium hydroxide or nickel(II) hydroxide
(b) Lead(II) sulfide or copper(II) sulfide
(c) Silver sulfate or magnesium fluoride
19.79 Which compound in each pair is more soluble in water?
(a) Strontium sulfate or barium chromate
(b) Calcium carbonate or copper(II) carbonate
(c) Barium iodate or silver chromate
19.80 Which compound in each pair is more soluble in water) I
(a) Barium sulfate or calcium sulfate
(a) Barium sulfate or calcium sulfate
(b) Calcium phosphate or magnesium phosphate
(c) Silver chloride or lead(II) sulfate
19.81 Which compound in each pair is more soluble in water?
(a) Manganese(II) hydroxide or calcium iodate
(b) Strontium carbonate or cadmium sulfide
(c) Silver cyanide or copper(I) iodide
19.82 Write equations to show whether the solubility of either of the following is affected by pH : (a) AgCl ; (b) $\mathrm{SrCO}_{3}$.
19.83 Write equations to show whether the solubility of either of the following is affected by pH : (a) CuBr ; (b) $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$.
19.84 Write equations to show whether the solubility of either of the following is affected by pH : (a) $\mathrm{Fe}(\mathrm{OH})_{2}$; (b) CuS .
19.85 Write equations to show whether the solubility of either of the following is affected by pH : (a) $\mathrm{PbI}_{2}$; (b) $\mathrm{Hg}_{2}(\mathrm{CN})_{2}$.
19.86 Does any solid $\mathrm{Cu}(\mathrm{OH})_{2}$ form when 0.075 g of KOH is dissolved in 1.0 L of $1.0 \times 10^{-3} \mathrm{M} \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}$ ?
19.87 Does any solid $\mathrm{PbCl}_{2}$ form when 3.5 mg of NaCl is dissolved in 0.250 L of $0.12 \mathrm{M} \mathrm{Pb}\left(\mathrm{NO}_{3}\right)_{2}$ ?
19.88 Does any solid $\mathrm{Ba}\left(\mathrm{IO}_{3}\right)_{2}$ form when 7.5 mg of $\mathrm{BaCl}_{2}$ is dissolved in $500 . \mathrm{mL}$ of $0.023 \mathrm{M} \mathrm{NaIO}_{3}$ ?
19.89 Does any solid $\mathrm{Ag}_{2} \mathrm{CrO}_{4}$ form when $2.7 \times 10^{-5} \mathrm{~g}$ of $\mathrm{AgNO}_{3}$ is dissolved in 15.0 mL of $4.0 \times 10^{-4} M \mathrm{~K}_{2} \mathrm{CrO}_{4}$ ?

## - Problems in Context

19.90 When blood is donated, sodium oxalate solution is used to precipitate $\mathrm{Ca}^{2+}$, which triggers clotting. A $104-\mathrm{mL}$ sample of
blood contains $9.7 \times 10^{-5} \mathrm{~g} \mathrm{Ca}^{2+} / \mathrm{mL}$. A technologist treats the sample with 100.0 mL of $0.1550 \mathrm{M} \mathrm{Na}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$. Calculate $\left[\mathrm{Ca}^{2+}\right]$ after the treatment. (See Appendix C for $K_{\text {sp }}$ of $\mathrm{CaC}_{2} \mathrm{O}_{4} \cdot \mathrm{H}_{2} \mathrm{O}$.)
19.91 A $50.0-\mathrm{mL}$ volume of $0.50 \mathrm{M} \mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}$ is mixed with 125 mL of $0.25 \mathrm{M} \mathrm{Cd}\left(\mathrm{NO}_{3}\right)_{2}$.
(a) If aqueous NaOH is added, which ion precipitates first? (See Appendix C.)
(b) Describe how the metal ions can be separated using NaOH .
(c) Calculate the $\left[\mathrm{OH}^{-}\right]$that will accomplish the separation.

## Equilibria Involving Complex Ions

(Sample Problems 19.13 and 19.14)

## - Concept Review Questions

19.92 How can a metal cation be at the center of a complex anion?
19.93 Write equations to show the stepwise reaction of $\mathrm{Cd}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}$ in an aqueous solution of KI to form $\mathrm{CdI}_{4}{ }^{2-}$. Show that $K_{\mathrm{f}(\mathrm{overall})}=K_{\mathrm{f} 1} \times K_{\mathrm{f} 2} \times K_{\mathrm{f} 3} \times K_{\mathrm{f} 4}$.
19.94 Consider the dissolution of PbS in water:
$\mathrm{PbS}(s)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{Pb}^{2+}(a q)+\mathrm{HS}^{-}(a q)+\mathrm{OH}^{-}(a q)$
Adding aqueous NaOH causes more PbS to dissolve. Does this violate Le Châtelier's principle? Explain.

## - Skill-Building Exercises (grouped in similar pairs)

19.95 Write a balanced equation for the reaction of $\mathrm{Hg}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}$ in aqueous KCN.
19.96 Write a balanced equation for the reaction of $\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}$ in aqueous NaCN .
19.97 Write a balanced equation for the reaction of $\mathrm{Ag}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}{ }^{+}$in

19.98 Write a balanced equation for the reaction of $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}$ in aqueous KF.
19.99 What is $\left[\mathrm{Ag}^{+}\right]$when 25.0 mL each of $0.044 \mathrm{M} \mathrm{AgNO}_{3}$ and $0.57 \mathrm{M} \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ are mixed $\left[K_{\mathrm{f}}\right.$ of $\left.\mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}=4.7 \times 10^{13}\right]$ ?
19.100 Potassium thiocyanate, KSCN , is often used to detect the presence of $\mathrm{Fe}^{3+}$ ions in solution through the formation of the red $\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{SCN}^{2+}$ (or, more simply, $\mathrm{FeSCN}^{2+}$ ). What is $\left[\mathrm{Fe}^{3+}\right.$ ] when 0.50 L each of $0.0015 M \mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3}$ and $0.20 M$ KSCN are mixed? $K_{\mathrm{f}}$ of $\mathrm{FeSCN}^{2+}=8.9 \times 10^{2}$.
19.101 Find the solubility of $\mathrm{Cr}(\mathrm{OH})_{3}$ in a buffer of pH 13.0 $\left[K_{\text {sp }}\right.$ of $\mathrm{Cr}(\mathrm{OH})_{3}=6.3 \times 10^{-31} ; K_{\mathrm{f}}$ of $\left.\mathrm{Cr}(\mathrm{OH})_{4}{ }^{-}=8.0 \times 10^{29}\right]$.
19.102 Find the solubility of AgI in $2.5 M \mathrm{NH}_{3}$ [ $K_{\text {sp }}$ of $\mathrm{AgI}=$ $8.3 \times 10^{-17} ; K_{\mathrm{f}}$ of $\left.\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}=1.7 \times 10^{7}\right]$.
19.103 When 0.84 g of $\mathrm{ZnCl}_{2}$ is dissolved in 245 mL of $0.150 M \mathrm{NaCN}$, what are $\left[\mathrm{Zn}^{2+}\right],\left[\mathrm{Zn}(\mathrm{CN})_{4}{ }^{2-}\right]$, and $\left[\mathrm{CN}^{-}\right]$ $\left[K_{\mathrm{f}}\right.$ of $\left.\mathrm{Zn}(\mathrm{CN})_{4}{ }^{2-}=4.2 \times 10^{19}\right]$ ?
19.104 When 2.4 g of $\mathrm{Co}\left(\mathrm{NO}_{3}\right)_{2}$ is dissolved in 0.350 L of 0.22 M KOH , what are $\left[\mathrm{Co}^{2+}\right],\left[\mathrm{Co}(\mathrm{OH})_{4}{ }^{2-}\right]$, and $\left[\mathrm{OH}^{-}\right]\left[K_{\mathrm{f}}\right.$ of $\left.\mathrm{Co}(\mathrm{OH})_{4}{ }^{2-}=5 \times 10^{9}\right]$ ?

## Comprehensive Problems

19.105 What volumes of 0.200 MCOOH and 2.00 M NaOH would make $500 . \mathrm{mL}$ of a buffer with the pH of one made from 475 mL of 0.200 M benzoic acid and 25 mL of 2.00 M NaOH ?
19.106 A microbiologist is preparing a medium on which to culture E. coli bacteria. She buffers the medium at pH 7.00 to minimize
the effect of acid-producing fermentation. What volumes of equimolar aqueous solutions of $\mathrm{K}_{2} \mathrm{HPO}_{4}$ and $\mathrm{KH}_{2} \mathrm{PO}_{4}$ must she combine to make $100 . \mathrm{mL}$ of the pH 7.00 buffer?
19.107 As an FDA physiologist, you need 0.700 L of formic acid-formate buffer with a pH of 3.74 .
(a) What is the required buffer-component concentration ratio?
(b) How do you prepare this solution from stock solutions of 1.0 M HCOOH and 1.0 M NaOH ?
(c) What is the final concentration of HCOOH in this solution?
19.108 Tris(hydroxymethyl)aminomethane $\left[\left(\mathrm{HOCH}_{2}\right)_{3} \mathrm{CNH}_{2}\right.$, known as TRIS] is a weak base used in biochemical experiments to make buffer solutions in the pH range of 7 to 9 . A certain TRIS buffer has a pH of 8.10 at $25^{\circ} \mathrm{C}$ and a pH of 7.80 at $37^{\circ} \mathrm{C}$. Why does the pH change with temperature?
19.109 Water flowing through pipes of carbon steel must be kept at pH 5 or greater to limit corrosion. If an $8.0 \times 10^{3} \mathrm{lb} / \mathrm{hr}$ water stream contains 10 ppm sulfuric acid and $0.015 \%$ acetic acid, how many pounds per hour of sodium acetate trihydrate must be added to maintain that pH ?
19.110 Gout is caused by an error in metabolism that leads to a buildup of uric acid in body fluids, which is deposited as slightly soluble sodium urate $\left(\mathrm{C}_{5} \mathrm{H}_{3} \mathrm{~N}_{4} \mathrm{O}_{3} \mathrm{Na}\right)$ in the joints. If the extracellular $\left[\mathrm{Na}^{+}\right]$is 0.15 M and the solubility of sodium urate is $0.085 \mathrm{~g} / 100 \mathrm{~mL}$, what is the minimum urate ion concentration (abbreviated $\left[\mathrm{Ur}^{-}\right]$) that will cause a deposit of sodium urate?
19.111 Cadmium ion in solution is analyzed by precipitation as the sulfide, a yellow compound used as a pigment in everything from artists' oil paints to glass and rubber. Calculate the molar solubility of cadmium sulfide at $25^{\circ} \mathrm{C}$.
19.112 In the discussion of cave formation inthe-chemial Con-DE nections essay ( p .859 ), the dissolution of $\mathrm{CO}_{2}$ (equation 1) has a $K_{\text {eq }}$ of $3.1 \times 10^{-2}$, and the formation of aqueous $\mathrm{Ca}\left(\mathrm{HCO}_{3}\right)_{2}$ (equation 2) has a $K_{\mathrm{eq}}$ of $1 \times 10^{-12}$. The fraction by volume of atmospheric $\mathrm{CO}_{2}$ is $3 \times 10^{-4}$. (a) Find $\left[\mathrm{CO}_{2}(a q)\right]$ in equilibrium with atmospheric $\mathrm{CO}_{2}$. (b) Determine $\left[\mathrm{Ca}^{2+}\right]$ arising from (equation 2) given current levels of atmospheric $\mathrm{CO}_{2}$. (c) Calculate $\left[\mathrm{Ca}^{2+}\right]$ if atmospheric $\mathrm{CO}_{2}$ doubles.
19.113 Phosphate systems form essential buffers in organisms. Calculate the pH of a buffer made by dissolving 0.80 mol of NaOH in 0.50 L of $1.0 \mathrm{M} \mathrm{H}_{3} \mathrm{PO}_{4}$.
19.114 The solubility of KCl is 3.7 M at $20^{\circ} \mathrm{C}$. Two beakers contain 100 mL of saturated KCl solution: $100 . \mathrm{mL}$ of 6.0 M HCl is added to the first beaker and $100 . \mathrm{mL}$ of 12 M HCl to the second.
(a) Find the ion-product constant of KCl at $20^{\circ} \mathrm{C}$.
(b) What mass, if any, of KCl will precipitate from each beaker?
19.115 It is possible to detect $\mathrm{NH}_{3}$ gas over $10^{-2} M \mathrm{NH}_{3}$. To what pH must $0.15 \mathrm{M} \mathrm{NH}_{4} \mathrm{Cl}$ be raised to form detectable $\mathrm{NH}_{3}$ ?
19.116 Manganese(II) sulfide is one of the compounds found in the nodules on the ocean floor that may eventually be a primary source of many transition metals. The solubility of MnS is $4.7 \times 10^{-4} \mathrm{~g} / 100 \mathrm{~mL}$ solution. Estimate the $K_{\text {sp }}$ of MnS .
19.117 The normal pH of blood is $7.40 \pm 0.05$ and is controlled in part by the $\mathrm{H}_{2} \mathrm{CO}_{3} / \mathrm{HCO}_{3}{ }^{-}$buffer system.
(a) Assuming that the $K_{\mathrm{a}}$ value for carbonic acid at $25^{\circ} \mathrm{C}$ applies to blood, what is the $\left[\mathrm{H}_{2} \mathrm{CO}_{3}\right] /\left[\mathrm{HCO}_{3}{ }^{-}\right]$ratio in normal blood?
(b) In a condition called acidosis, the blood is too acidic. What is the $\left[\mathrm{H}_{2} \mathrm{CO}_{3}\right] /\left[\mathrm{HCO}_{3}{ }^{-}\right]$ratio in a patient whose blood pH is 7.20 ?
19.118 A bioengineer preparing cells for cloning bathes a small piece of rat epithelial tissue in a TRIS buffer (see Problem 19.108). The buffer is made by dissolving 43.0 g of TRIS ( $\mathrm{p} K_{\mathrm{b}}=5.91$ ) in enough 0.095 M HCl to make 1.00 L of solution. What is the molarity of TRIS and the pH of the buffer?
19.119 Sketch a qualitative curve for the titration of ethylenediamine, $\mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}$, with 0.1 M HCl .
19.120 A solution contains $0.10 \mathrm{M} \mathrm{ZnCl}_{2}$ and $0.020 \mathrm{M} \mathrm{MnCl}_{2}$. Given the following information, how would you adjust the pH to separate the ions as their sulfides $\left(\left[\mathrm{H}_{2} \mathrm{~S}\right]\right.$ of a saturated aqueous solution at $25^{\circ} \mathrm{C}=0.10 \mathrm{M} ; K_{\mathrm{w}}=1.0 \times 10^{-14}$ at $\left.25^{\circ} \mathrm{C}\right)$ ?
$\begin{array}{ll}\mathrm{MnS}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{Mn}^{2+}+\mathrm{HS}^{-}+\mathrm{OH}^{-} & K_{\text {sp }}=3 \times 10^{-11} \\ \mathrm{ZnS}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{Zn}^{2+}+\mathrm{HS}^{-}+\mathrm{OH}^{-} & K_{\text {sp }}=2 \times 10^{-22} \\ \mathrm{H}_{2} \mathrm{~S}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{HS}^{-} & K_{\mathrm{a} 1}=9 \times 10^{-8}\end{array}$
19.121 Amino acids [general formula $\mathrm{NH}_{2} \mathrm{CH}(\mathrm{R}) \mathrm{COOH}$ ] can be considered polyprotic acids. In many cases, the R group contains additional amine and carboxyl groups.
(a) Can an amino acid dissolved in pure water have a protonated COOH group and an unprotonated $\mathrm{NH}_{2}$ group ( $K_{\mathrm{a}}$ of COOH group $=4.47 \times 10^{-3} ; K_{\mathrm{b}}$ of $\mathrm{NH}_{2}$ group $\left.=6.03 \times 10^{-5}\right)$ ? Use glycine, $\mathrm{NH}_{2} \mathrm{CH}_{2} \mathrm{COOH}$, to explain why.
(b) Calculate $\left[{ }^{+} \mathrm{NH}_{3} \mathrm{CH}_{2} \mathrm{COO}^{-}\right] /\left[{ }^{+} \mathrm{NH}_{3} \mathrm{CH}_{2} \mathrm{COOH}\right]$ at pH 5.5 .
(c) The R group of lysine is $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\left(\mathrm{p} K_{\mathrm{b}}=\right.$ 3.47). Draw the structure of lysine at pH 1 , physiological pH (~7), and pH 13.
(d) The R group of glutamic acid is $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{COOH}\left(\mathrm{p} K_{\mathrm{a}}=\right.$ 4.07). Of the forms of glutamic acid that are shown below, which predominates at (1) pH 1 , (2) physiological $\mathrm{pH}(\sim 7)$, and (3) H月 $_{\text {HonceI }}$

19.122 The scene below depicts a saturated solution of $\mathrm{MCl}_{2}(s)$ in the presence of dilute aqueous NaCl ; each sphere represents $1.0 \times 10^{-6} \mathrm{~mol}$ of ion, and the volume is 250.0 mL (solid $\mathrm{MCl}_{2}$ is shown as green chunks; $\mathrm{Na}^{+}$ions and water molecules are not shown).

(a) Calculate the $K_{\text {sp }}$ of $\mathrm{MCl}_{2}$.
(b) If $\mathrm{M}\left(\mathrm{NO}_{3}\right)_{2}(s)$ is added, is there an increase, decrease, or no change in the number of $\mathrm{Cl}^{-}$particles? In the $K_{\mathrm{sp}}$ ? In the mass of $\mathrm{MCl}_{2}(s)$ ?
19.123 Tooth enamel consists of hydroxyapatite, $\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}$ $\left(K_{\mathrm{sp}}=6.8 \times 10^{-37}\right)$. Fluoride ion added to drinking water reacts with $\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}$ to form the more tooth decay-resistant fluorapatite, $\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F}\left(K_{\text {sp }}=1.0 \times 10^{-60}\right)$. Fluoridated water has dramatically decreased cavities among children. Calculate the solubility of $\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH}$ and of $\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F}$ in water.
19.124 The acid-base indicator ethyl orange turns from red to yellow over the pH range 3.4 to 4.8. Estimate $K_{\mathrm{a}}$ for ethyl orange.
19.125 Use the values obtained in Problem 19.54 to sketch a curve of $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$vs. mL of added titrant. Are there advantages or disadvantages to viewing the results in this form? Explain.
19.126 Instrumental acid-base titrations use a pH meter to monitor the changes in pH and volume. The equivalence point is found from the volume at which the curve has the steepest slope.
(a) Use Figure 19.7 to calculate the slope $\Delta \mathrm{pH} / \Delta V$ for all pairs of adjacent points and to calculate the average volume ( $V_{\text {avg }}$ ) for each interval.
(b) Plot $\Delta \mathrm{pH} / \Delta V$ vs. $V_{\text {avg }}$ to find the steepest slope, and thus the volume at the equivalence point. (For example, the first pair of points gives $\Delta \mathrm{pH}=0.22, \Delta V=10.00 \mathrm{~mL}$; hence, $\Delta \mathrm{pH} / \Delta V=$ $0.022 \mathrm{~mL}^{-1}$, and $V_{\text {avg }}=5.00 \mathrm{~mL}$.)
19.127 What is the pH of a solution of $6.5 \times 10^{-9} \mathrm{~mol}$ of $\mathrm{Ca}(\mathrm{OH})_{2}$ in 10.0 L of water $\left[K_{\mathrm{sp}}\right.$ of $\left.\mathrm{Ca}(\mathrm{OH})_{2}=6.5 \times 10^{-6}\right]$ ?
19.128 The Henderson-Hasselbalch equation gives a relationship for obtaining the pH of a buffer solution consisting of HA and
 buffer solution consisting of B and $\mathrm{BH}^{+}$
19.129 Muscle physiologists study the accumulation of lactic acid $\left[\mathrm{CH}_{3} \mathrm{CH}(\mathrm{OH}) \mathrm{COOH}\right]$ during exercise. Food chemists study its occurrence in sour milk, beer, wine, and fruit. Industrial microbiologists study its formation by various bacterial species from carbohydrates. A biochemist prepares a lactic acid-lactate buffer by mixing 225 mL of 0.85 M lactic acid ( $K_{\mathrm{a}}=1.38 \times 10^{-4}$ ) with 435 mL of 0.68 M sodium lactate. What is the buffer pH ?
19.130 A student wants to dissolve the maximum amount of $\mathrm{CaF}_{2}$ ( $K_{\text {sp }}=3.2 \times 10^{-11}$ ) to make 1 L of aqueous solution.
(a) Into which of the following solvents should she dissolve the salt?
(I) Pure water
(II) 0.01 M HF
(III) 0.01 M NaOH
(IV) 0.01 M HCl
(V) $0.01 \mathrm{M} \mathrm{Ca}(\mathrm{OH})_{2}$
(b) Which would dissolve the least amount of salt?
19.131 A 500.-mL solution consists of 0.050 mol of solid NaOH and 0.13 mol of hypochlorous acid ( $\mathrm{HClO} ; K_{\mathrm{a}}=3.0 \times 10^{-8}$ ) dissolved in water.
(a) Aside from water, what is the concentration of each species that is present?
(b) What is the pH of the solution?
(c) What is the pH after adding 0.0050 mol of HCl to the flask?
19.132 Calcium ion present in water supplies is easily precipitated as calcite $\left(\mathrm{CaCO}_{3}\right)$ :

$$
\mathrm{Ca}^{2+}(a q)+\mathrm{CO}_{3}^{2-}(a q) \rightleftharpoons \mathrm{CaCO}_{3}(s)
$$

Because the $K_{\text {sp }}$ decreases with temperature, heating hard water forms a calcite "scale," which clogs pipes and water heaters. Find the solubility of calcite in water (a) at $10^{\circ} \mathrm{C}\left(K_{\text {sp }}=\right.$ $\left.4.4 \times 10^{-9}\right)$ and (b) at $30^{\circ} \mathrm{C}\left(K_{\text {sp }}=3.1 \times 10^{-9}\right)$.
19.133 Calculate the molar solubility of $\mathrm{Hg}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\left(K_{\mathrm{sp}}=\right.$ $1.75 \times 10^{-13}$ ) in $0.13 M \mathrm{Hg}_{2}\left(\mathrm{NO}_{3}\right)_{2}$.
19.134 The well water in an area is "hard" because it is in equilibrium with $\mathrm{CaCO}_{3}$ in the surrounding rocks. What is the concentration of $\mathrm{Ca}^{2+}$ in the well water (assuming the water's pH is such that the $\mathrm{CO}_{3}{ }^{2-}$ ion is not significantly protonated)? (See Appendix C for $K_{\text {sp }}$ of $\mathrm{CaCO}_{3}$.)
19.135 Environmental engineers use alkalinity as a measure of the capacity of carbonate buffering systems in water samples:
Alkalinity $(\mathrm{mol} / \mathrm{L})=\left[\mathrm{HCO}_{3}{ }^{-}\right]+2\left[\mathrm{CO}_{3}{ }^{2-}\right]+\left[\mathrm{OH}^{-}\right]-\left[\mathrm{H}^{+}\right]$
Find the alkalinity of a water sample that has a pH of 9.5 , $26.0 \mathrm{mg} / \mathrm{L} \mathrm{CO}_{3}{ }^{2-}$, and $65.0 \mathrm{mg} / \mathrm{L} \mathrm{HCO}_{3}{ }^{-}$.
19.136 Human blood contains one buffer system based on phosphate species and one on carbonate species. Assuming that blood has a normal pH of 7.4 , what are the principal phosphate and carbonate species present? What is the ratio of the two phosphate species? (In the presence of the dissolved ions and other species in blood, $K_{\mathrm{a} 1}$ of $\mathrm{H}_{3} \mathrm{PO}_{4}=1.3 \times 10^{-2}, K_{\mathrm{a} 2}=$ $2.3 \times 10^{-7}$, and $K_{\mathrm{a} 3}=6 \times 10^{-12} ; K_{\mathrm{a} 1}$ of $\mathrm{H}_{2} \mathrm{CO}_{3}=8 \times 10^{-7}$ and $K_{\mathrm{a} 2}=1.6 \times 10^{-10}$.)
19.137 Litmus is an organic dye extracted from lichens. It is red below pH 4.5 and blue above pH 8.3 . One drop of either 0.1 M HCl ( pH 1 ) or a pH 3 buffer changes blue litmus paper to red, but a drop of 0.001 M HCl (also pH 3 ) does not. Explain.
19.138 An environmental technician collects a sample of rainwater.

EDBAAMThefat, her pH meter isn't working, so she uses indicator solutions to estimate the pH . A piece of litmus paper turns red, indicating acidity, so she divides the sample into thirds and obtains the following results: thymol blue turns yellow; bromphenol blue turns green; and methyl red turns red. Estimate the pH of the rainwater.
19.139 A $0.050 \mathrm{M} \mathrm{H}_{2} \mathrm{~S}$ solution contains $0.15 \mathrm{M} \mathrm{NiCl}_{2}$ and 0.35 M $\mathrm{Hg}\left(\mathrm{NO}_{3}\right)_{2}$. What pH is required to precipitate the maximum amount of HgS but none of the NiS? (See Appendix C.)
19.140 Quantitative analysis of $\mathrm{Cl}^{-}$ion is often performed by a titration with silver nitrate, using sodium chromate as an indicator. As standardized $\mathrm{AgNO}_{3}$ is added, both white AgCl and red $\mathrm{Ag}_{2} \mathrm{CrO}_{4}$ precipitate, but so long as some $\mathrm{Cl}^{-}$remains, the $\mathrm{Ag}_{2} \mathrm{CrO}_{4}$ redissolves as the mixture is stirred. When the red color is permanent, the equivalence point has been reached.
(a) Calculate the equilibrium constant for the reaction

$$
2 \mathrm{AgCl}(s)+\mathrm{CrO}_{4}{ }^{2-}(a q) \rightleftharpoons \mathrm{Ag}_{2} \mathrm{CrO}_{4}(s)+2 \mathrm{Cl}^{-}(a q)
$$

(b) Explain why the silver chromate redissolves.
(c) If $25.00 \mathrm{~cm}^{3}$ of 0.1000 M NaCl is mixed with $25.00 \mathrm{~cm}^{3}$ of $0.1000 \mathrm{M} \mathrm{AgNO}_{3}$, what is the concentration of $\mathrm{Ag}^{+}$remaining in solution? Is this sufficient to precipitate any silver chromate?
19.141 An ecobotanist separates the components of a tropical bark extract by chromatography. She discovers a large proportion of quinidine, a dextrorotatory isomer of quinine used for control of arrhythmic heartbeat. Quinidine has two basic nitrogens ( $K_{\mathrm{b} 1}=4.0 \times 10^{-6}$ and $K_{\mathrm{b} 2}=1.0 \times 10^{-10}$ ). To measure the concentration, she carries out a titration. Because of the low
solubility of quinidine, she first protonates both nitrogens with excess HCl and titrates the acidified solution with standardized base. A $33.85-\mathrm{mg}$ sample of quinidine $(\mathcal{M}=324.41 \mathrm{~g} / \mathrm{mol})$ is acidified with 6.55 mL of 0.150 M HCl .
(a) How many milliliters of 0.0133 M NaOH are needed to titrate the excess HCl ?
(b) How many additional milliliters of titrant are needed to reach the first equivalence point of quinidine dihydrochloride?
(c) What is the pH at the first equivalence point?
19.142 Some kidney stones form by the precipitation of calcium oxalate monohydrate $\left(\mathrm{CaC}_{2} \mathrm{O}_{4} \cdot \mathrm{H}_{2} \mathrm{O}, K_{\text {sp }}=2.3 \times 10^{-9}\right)$. The pH of urine varies from 5.5 to 7.0 , and the average $\left[\mathrm{Ca}^{2+}\right]$ in urine is $2.6 \times 10^{-3} \mathrm{M}$.
(a) If the [oxalic acid] in urine is $3.0 \times 10^{-13} M$, will kidney stones form at $\mathrm{pH}=5.5$ ?
(b) At $\mathrm{pH}=7.0$ ?
(c) Vegetarians have a urine pH above 7. Are they more or less likely to form kidney stones?
19.143 A biochemist needs a medium for acid-producing bacteria. The pH of the medium must not change by more than 0.05 pH units for every 0.0010 mol of $\mathrm{H}_{3} \mathrm{O}^{+}$generated by the organisms per liter of medium. A buffer consisting of 0.10 M HA and $0.10 \mathrm{M} \mathrm{A}^{-}$is included in the medium to control its pH . What volume of this buffer must be included in 1.0 L of medium?
$19.144 \mathrm{~A} 35.00-\mathrm{mL}$ solution of 0.2500 M HF is titrated with a standardized 0.1532 M solution of NaOH at $25^{\circ} \mathrm{C}$.
(a) What is the pH of the HF solution before titrant is added?
(b) How many milliliters of titrant are required to reach the equivalence point?
(c) What is the pH at 0.50 mL before the equatenecopoint? PDE
(d) What is the pH at the equivalence point?
(e) What is the pH at 0.50 mL after the equivalence point?
19.145 Because of the toxicity of mercury compounds, mercury(I) chloride is used in antibacterial salves. The mercury(I) ion $\left(\mathrm{Hg}_{2}{ }^{2+}\right)$ consists of two bound $\mathrm{Hg}^{+}$ions.
(a) What is the empirical formula of mercury(I) chloride?
(b) Calculate $\left[\mathrm{Hg}_{2}{ }^{2+}\right]$ in a saturated solution of mercury(I) chloride $\left(K_{\text {sp }}=1.5 \times 10^{-18}\right)$.
(c) A seawater sample contains 0.20 lb of NaCl per gallon. Find $\left[\mathrm{Hg}_{2}{ }^{2+}\right]$ if the seawater is saturated with mercury(I) chloride.
(d) How many grams of mercury(I) chloride are needed to saturate $4900 \mathrm{~km}^{3}$ of pure water (the volume of Lake Michigan)?
(e) How many grams of mercury(I) chloride are needed to saturate $4900 \mathrm{~km}^{3}$ of seawater?
19.146 A lake that has a surface area of 10.0 acres ( 1 acre $=$ $4.840 \times 10^{3} \mathrm{yd}^{2}$ ) receives 1.00 in . of rain of pH 4.20 . (Assume that the acidity of the rain is due to a strong, monoprotic acid.)
(a) How many moles of $\mathrm{H}_{3} \mathrm{O}^{+}$are in the rain falling on the lake?
(b) If the lake is unbuffered $(\mathrm{pH}=7.00)$ and its average depth is 10.0 ft before the rain, find the pH after the rain has been mixed with lake water. (Ignore runoff from the surrounding land.)
(c) If the lake contains hydrogen carbonate ions $\left(\mathrm{HCO}_{3}{ }^{-}\right)$, what mass of $\mathrm{HCO}_{3}{ }^{-}$would neutralize the acid in the rain?
$19.147 \mathrm{~A} 35.0-\mathrm{mL}$ solution of $0.075 \mathrm{M} \mathrm{CaCl}_{2}$ is mixed with 25.0 mL of $0.090 \mathrm{M} \mathrm{BaCl}_{2}$.
(a) If aqueous KF is added, which fluoride precipitates first?
(b) Describe how the metal ions can be separated using KF to form the fluorides.
(c) Calculate the fluoride ion concentration that will accomplish the separation.
19.148 Even before the industrial age, rainwater was slightly acidic due to dissolved $\mathrm{CO}_{2}$. Use the following data to calculate pH of unpolluted rainwater at $25^{\circ} \mathrm{C}$ : vol $\%$ in air of $\mathrm{CO}_{2}=$ 0.033 vol \%; solubility of $\mathrm{CO}_{2}$ in pure water at $25^{\circ} \mathrm{C}$ and $1 \mathrm{~atm}=88 \mathrm{~mL} \mathrm{CO}_{2} / 100 \mathrm{~mL} \mathrm{H}_{2} \mathrm{O} ; K_{\mathrm{a} 1}$ of $\mathrm{H}_{2} \mathrm{CO}_{3}=4.5 \times 10^{-7}$.
19.149 Seawater at the surface has a pH of about 8.5.
(a) Which of the following species has the highest concentration at this $\mathrm{pH}: \mathrm{H}_{2} \mathrm{CO}_{3} ; \mathrm{HCO}_{3}^{-} ; \mathrm{CO}_{3}{ }^{2-}$ ? Explain.
(b) What are the concentration ratios $\left[\mathrm{CO}_{3}{ }^{2-}\right] /\left[\mathrm{HCO}_{3}{ }^{-}\right]$and $\left[\mathrm{HCO}_{3}{ }^{-}\right] /\left[\mathrm{H}_{2} \mathrm{CO}_{3}\right]$ at this pH ?
(c) In the deep sea, light levels are low, and the pH is around 7.5. Suggest a reason for the lower pH at the greater ocean depth. (Hint: Consider the presence or absence of plant and animal life, and the effects on carbon dioxide concentrations.)
19.150 Ethylenediaminetetraacetic acid (abbreviated $\mathrm{H}_{4}$ EDTA) is a tetraprotic acid. Its salts are used to treat toxic metal poisoning by forming soluble complex ions that are then excreted. Because EDTA ${ }^{4-}$ also binds essential calcium ions, it is often administered as the calcium disodium salt. For example, when $\mathrm{Na}_{2} \mathrm{Ca}($ EDTA $)$ is given to a patient, the $[\mathrm{Ca}(E D T A)]^{2-}$ ions react with circulating $\mathrm{Pb}^{2+}$ ions and the metal ions are exchanged:

$$
\begin{aligned}
& {[\mathrm{Ca}(\text { EDTA })]^{2-}(a q)+\mathrm{Pb}^{2+}(a q) \rightleftharpoons} \\
& \quad[\mathrm{Pb}(\text { EDTA })]^{2-}(a q)+\mathrm{Ca}^{2+}(a q) \quad K_{\mathrm{c}}=2.5 \times 10^{7}
\end{aligned}
$$

A child has a dangerous blood lead level of $120 \mu \mathrm{~g} / 100 \mathrm{~mL}$. If the child is administered $100 . \mathrm{mL}$ of $0.10 \mathrm{M} \mathrm{Na}_{2} \mathrm{Ca}$ (EDTA), assuming the exchange reaction and excretion process are 10 日elfient deatis the final concentration of $\mathrm{Pb}^{2+}$ in $\mu \mathrm{g} / 100 \mathrm{~mL}$ blood? (Total blood volume is 1.5 L .)
19.151 Buffers that are based on 3-morpholinopropanesulfonic acid (MOPS) are often used in RNA analysis. The useful pH range of a MOPS buffer is 6.5 to 7.9 . Estimate the $K_{\mathrm{a}}$ of MOPS.
19.152 NaCl is purified by adding HCl to a saturated solution of $\mathrm{NaCl}(317 \mathrm{~g} / \mathrm{L})$. When 28.5 mL of 8.65 M HCl is added to 0.100 L of saturated solution, what mass $(\mathrm{g})$ of pure NaCl precipitates?
19.153 Scenes A to D represent tiny portions of 0.10 M aqueous solutions of a weak acid HA (red and blue; $K_{\mathrm{a}}=4.5 \times 10^{-5}$ ), its conjugate base $\mathrm{A}^{-}$(red), or a mixture of the two (only these species are shown):

(a) Which scene(s) show(s) a buffer?
(b) What is the pH of each solution?
(c) Arrange the scenes in sequence, assuming that they represent stages in a weak acid-strong base titration.
(d) Which scene represents the titration at its equivalence point?
19.154 Scenes A to C represent aqueous solutions of the slightly soluble salt MZ (only the ions of this salt are shown):

$$
\mathrm{MZ}(s) \rightleftharpoons \mathrm{M}^{2+}(a q)+\mathrm{Z}^{2-}(a q)
$$

(a) Which scene represents the solution just after solid MZ is stirred thoroughly in distilled water?
(b) If each sphere represents $2.5 \times 10^{-6} \mathrm{M}$ of ions, what is the $K_{\text {sp }}$ of MZ?
(c) Which scene represents the solution after $\mathrm{Na}_{2} \mathrm{Z}(a q)$ is added?
(d) If $\mathrm{Z}^{2-}$ is $\mathrm{CO}_{3}{ }^{2-}$, which scene represents the solution after the pH has been lowered?
19.155 The solubility of $\mathrm{Ag}(\mathrm{I})$ in aqueous solutions containing different concentrations of $\mathrm{Cl}^{-}$is based on the following equilibria:

$$
\begin{aligned}
\mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q) & \rightleftharpoons \mathrm{AgCl}(s) \\
\mathrm{Ag}^{+}(a q)+2 \mathrm{Cl}^{-}(a q) & \rightleftharpoons \mathrm{AgCl}_{2}^{-}(a q)
\end{aligned} \begin{aligned}
K_{\mathrm{sp}} & =1.8 \times 10^{-10} \\
K_{\mathrm{f}} & =1.8 \times 10^{5}
\end{aligned}
$$

When solid AgCl is shaken with a solution containing $\mathrm{Cl}^{-}, \mathrm{Ag}(\mathrm{I})$ is present as both $\mathrm{Ag}^{+}$and $\mathrm{AgCl}_{2}^{-}$. The solubility of AgCl is the sum of the concentrations of $\mathrm{Ag}^{+}$and $\mathrm{AgCl}_{2}{ }^{-}$.
(a) Show that $\left[\mathrm{Ag}^{+}\right]$in solution is given by

$$
\left[\mathrm{Ag}^{+}\right]=1.8 \times 10^{-10} /\left[\mathrm{Cl}^{-}\right]
$$

and that $\left[\mathrm{AgCl}_{2}^{-}\right]$in solution is given by

$$
\left[\mathrm{AgCl}_{2}^{-}\right]=\left(3.2 \times 10^{-5}\right)\left(\left[\mathrm{Cl}^{-}\right]\right)
$$

(b) Find the $\left[\mathrm{Cl}^{-}\right]$at which $\left[\mathrm{Ag}^{+}\right]=\left[\mathrm{AgCl}_{2}^{-}\right]$.
(c) Explain the shape of a plot of AgCl solubility vs. $\left[\mathrm{Cl}^{-}\right]$.
(d) Find the solubility of AgCl at the $\left[\mathrm{Cl}^{-}\right]$of part (b), which is the minimum solubility of AgCl in the presence of $\mathrm{Cl}^{-}$.
19.156 EDTA binds metal ions to form complex ions (see Problem 19.150), so it is used to determine the concentrations of metal ions in solution:

$$
\mathrm{M}^{n+}(a q)+\mathrm{EDTA}^{4-}(a q) \longrightarrow \operatorname{MEDTA}^{n-4}(a q)
$$

A $50.0-\mathrm{mL}$ sample of $0.048 \mathrm{M} \mathrm{Co}^{2+}$ is titrated with 0.050 M EDTA ${ }^{4-}$. Find $\left[\mathrm{Co}^{2+}\right]$ and $\left[\mathrm{EDTA}^{4-}\right]$ after (a) 25.0 mL and (b) 75.0 mL of EDTA $^{4-}$ are added $\left(\log K_{\mathrm{f}}\right.$ of CoEDTA ${ }^{2-}=$ 16.31).

## 20

Thermodynamics and the Steam Engine The relationship between heat and work was first applied most practically in the $19^{\text {th }}$ century to understand and improve the newly invented steam engine. In this chapter, we examine this relationship to learn the real-world limit on the energy that can be obtained from any chemical or physical change. In the process, we see why reactions occur.

20.4 Free Energy, Equilibrium, and Reaction Direction
n the last few chapters, we've posed and answered some essential questions about chemical and physical change: How fast does the change occur, and how is this rate affected by concentration and temperature? How much product will be present when the net change ceases, and how is this yield affected by concentration and temperature? We've explored these questions for systems ranging from the stratosphere to a limestone cave to the cells of your body.

But why does the change occur in the first place? From everyday experience, it seems that some changes happen by themselves-that is, spontaneouslyalmost as if a force were driving them in one direction and not the other. Turn on a gas stove, for example, and the methane mixes with oxygen and burns immediately to yield carbon dioxide and water vapor. But those products will not remake methane and oxygen no matter how long they mix. A steel shovel left outside slowly rusts, but put a rusty one outside and it won't become shiny. A cube of sugar dissolves in a cup of coffee after a few seconds of stirring, but stir for another century and the dissolved sugar won't ever reappear as a cube.

Chemists speak of a process that occurs by itself as being spontaneous. Some absorb energy, whereas others release it. The principles of thermodynamics, which were developed almost 200 years ago to help utilize the power derived from steam, allow us to understand the nature of spontaneous change. Despite their narrow historical purpose, these principles apply, as far as we know, to every system in the universe!

IN THIS CHAPTER . . . We begin by looking for a criterion to predict the direction of a spontaneous change. A review of the first law of thermodynamics shows that it accounts for the quantity of energy in a change but not the direction of the change. The sign of the enthalpy change is not a criterion for predicting direction either. Rather, we find this criterion in the second law of thermodynamics and its quantitative application of entropy ( $S$ ), the state function that relates to the natural tendency of a system's energy to become more dispersed. We examine these ideas for both exothermic and endothermic changes. The concept of free energy we develop gives a simplified criterion for spontaneous change, and we see how it relates to the work a system can do. Finally, we consider the key relationship between the free energy change and the equilibrium constant of a reaction.

### 20.1 THE SECOND LAW OF THERMODYNAMICS: PREDICTING SPONTANEOUS CHANGE

In a formal sense, a spontaneous change of a system, whether a chemical or physical change, or just a change in location, is one that occurs by itself under specified conditions, without a continuous input of energy from outside the system. The freezing of water, for example, is spontaneous for the system at 1 atm and $-5^{\circ} \mathrm{C}$. A spontaneous process such as burning or falling may need a little "push" to get started-a spark to ignite gasoline, a shove to knock a book off your desk—but once the process begins, it keeps going without the need for any continuous external input of energy.

In contrast, for a nonspontaneous change to occur, the surroundings must supply the system with a continuous input of energy. A book falls spontaneously, but it rises only if something else, such as a human hand (or a strong wind), supplies energy in the form of work. Under a given set of conditions, if a change is spontaneous in one direction, it is not spontaneous in the other.

The term spontaneous does not mean instantaneous or have anything to say about how long a process takes to occur; it means that, given enough time, the process will happen by itself. Many processes are spontaneous but slowripening, rusting, and (happily!) aging.

## Concepts \& Skills to Review before you study this chapter

- internal energy, heat, and work (Section 6.1)
- state functions (Section 6.1) and standard states (Section 6.6)
- enthalpy, $\Delta H$, and Hess's law (Sections 6.2 and 6.5)
- entropy and solution formation (Section 13.3)
- comparing $Q$ and $K$ to find reaction direction (Section 17.4)

A chemical reaction proceeding toward equilibrium is an example of a spontaneous change. As you learned in Chapter 17, we can predict the net direction of the reaction-its spontaneous direction-by comparing the reaction quotient $(Q)$ with the equilibrium constant $(K)$. But why is there a drive to attain equilibrium? And what determines the value of the equilibrium constant? Can we tell the direction of a spontaneous change in cases that are not as obvious as burning gasoline or falling books? Because energy changes seem to be involved, let's begin by reviewing the idea of conservation of energy to see whether it can help uncover the criterion for spontaneity.

## Limitations of the First Law of Thermodynamics

In Chapter 6, we discussed the first law of thermodynamics (the law of conservation of energy) and its application to chemical and physical systems. The first law states that the internal energy $(E)$ of a system, the sum of the kinetic and potential energy of all its particles, changes when heat $(q)$ and/or work $(w)$ are gained or lost:

$$
\Delta E=q+w
$$

Whatever is not part of the system (sys) is part of the surroundings (surr), so the system and surroundings together constitute the universe (univ):

$$
E_{\text {univ }}=E_{\text {sys }}+E_{\text {surr }}
$$

Heat and/or work gained by the system is lost by the surroundings, and vice versa:

$$
(q+w)_{\text {sys }}=-(q+w)_{\text {surr }}
$$

It follows from these ideas that the total energy of the universe is constant:*

$$
\Delta E_{\text {sys }}=-\Delta E_{\text {surr }} \quad \text { therefore } \quad \Delta E_{\text {sys }}+\Delta E_{\text {surr }}=0=\Delta E_{\text {univ }}
$$

ATs thefinst lamu does? It certainly accounts for the energy involved. When gasoline burns in your car's engine, the first law states that the potential energy difference between the chemical bonds in the fuel mixture and those in the exhaust gases is converted to the kinetic energy of the moving car and its parts plus the heat released to the environment. When an ice cube melts in your hand, the first law tells that energy from your hand was transferred to the ice to change it to a liquid. If you could measure the work and heat involved in each case, you would find that energy is conserved as it is converted from one form to another.

However, the first law does not help us make sense of the direction of the change. Why doesn't the heat released in the car engine convert exhaust fumes back into gasoline and oxygen? Why doesn't the pool of water in your cupped hand transfer the heat back to your hand and refreeze? Neither of these events would violate the first law-energy would still be conserved-but they never happen. The first law by itself tells nothing about the direction of a spontaneous change, so we must look elsewhere for a way to predict that direction.

## The Sign of $\Delta H$ Cannot Predict Spontaneous Change

In the mid-19 ${ }^{\text {th }}$ century, some scientists thought that the sign of the enthalpy change $(\Delta H)$, the heat gained or lost at constant pressure $\left(q_{P}\right)$, was the criterion for spontaneity. They thought that exothermic processes $(\Delta H<0)$ were spontaneous and endothermic ones $(\Delta H>0)$ were nonspontaneous. This hypothesis has a lot of support from observation; after all, many spontaneous processes are

[^30]exothermic. All combustion reactions, such as methane burning, are spontaneous and exothermic:
$$
\mathrm{CH}_{4}(g)+2 \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-802 \mathrm{~kJ}
$$

Iron metal oxidizes spontaneously and exothermically:

$$
2 \mathrm{Fe}(s)+\frac{3}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{Fe}_{2} \mathrm{O}_{3}(s) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-826 \mathrm{~kJ}
$$

Ionic compounds, such as NaCl , form spontaneously and exothermically from their elements:

$$
\mathrm{Na}(s)+\frac{1}{2} \mathrm{Cl}_{2}(g) \longrightarrow \mathrm{NaCl}(s) \quad \Delta H_{\mathrm{rxn}}^{\circ}=-411 \mathrm{~kJ}
$$

However, in many other cases, the sign of $\Delta H$ is no help. An exothermic process occurs spontaneously under certain conditions, whereas the opposite, endothermic, process occurs spontaneously under other conditions. Consider the following examples of phase changes, dissolving salts, and chemical changes.

At ordinary pressure, water freezes below $0^{\circ} \mathrm{C}$ but melts above $0^{\circ} \mathrm{C}$. Both changes are spontaneous, but the first is exothermic and the second endothermic:

$$
\begin{array}{ll}
\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(s) \\
\mathrm{H}_{2} \mathrm{O}(s) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)
\end{array} \quad \begin{aligned}
& \Delta H_{\mathrm{rxn}}^{\circ}=-6.02 \mathrm{~kJ}\left(\text { exothermic; spontaneous at } T<0^{\circ} \mathrm{C}\right) \\
& \left.\Delta H_{\mathrm{rxn}}^{\circ}=+6.02 \mathrm{~kJ} \text { (endothermic; spontaneous at } T>0^{\circ} \mathrm{C}\right)
\end{aligned}
$$

At ordinary pressure and room temperature, liquid water vaporizes spontaneously in dry air, another endothermic change:

$$
\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{O}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=+44.0 \mathrm{~kJ}
$$

In fact, all melting and vaporizing are endothermic changes that are spontaneous under proper conditions.

Recall from Chapter 13 that most water-soluble salts have a positive $\Delta H_{\text {soln }}^{\circ}$ yet dissolve spontaneously:

$$
\begin{aligned}
& \mathrm{NaCl}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{Na}^{+}(a q)+\mathrm{Cl}^{-}(a q) \quad \Delta H_{\text {soln }}^{\circ}=+3.9 \mathrm{~kJ}
\end{aligned}
$$

$$
\begin{aligned}
& \mathrm{NH}_{4} \mathrm{NO}_{3}(s) \xrightarrow{\mathrm{H}_{2} \mathrm{O}} \mathrm{NH}_{4}^{+}(a q)+\mathrm{NO}_{3}^{-}(a q) \quad \Delta H_{\text {soln }}^{\circ}=+25.7 \mathrm{~kJ}
\end{aligned}
$$

Some endothermic chemical changes are also spontaneous:

$$
\begin{aligned}
& \mathrm{N}_{2} \mathrm{O}_{5}(s) \longrightarrow 2 \mathrm{NO}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \\
& \Delta H_{\mathrm{rxn}}^{\circ}=+109.5 \mathrm{~kJ} \\
& \mathrm{Ba}(\mathrm{OH})_{2} \cdot 8 \mathrm{H}_{2} \mathrm{O}(s)+2 \mathrm{NH}_{4} \mathrm{NO}_{3}(s) \longrightarrow \\
& \mathrm{Ba}^{2+}(a q)+2 \mathrm{NO}_{3}^{-}(a q)+2 \mathrm{NH}_{3}(a q)+10 \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta H_{\mathrm{rxn}}^{\circ}=+62.3 \mathrm{~kJ}
\end{aligned}
$$

In the second reaction, the released waters of hydration solvate the ions, but the reaction mixture cannot absorb heat from the surroundings quickly enough, and the container becomes so cold that a wet block of wood freezes to it (Figure 20.1).

## Freedom of Particle Motion and Dispersal of Particle Energy

What features common to the previous endothermic processes can help us see why they occur spontaneously? In each case, the particles that make up the matter have more freedom of motion after the change occurs. And this means that their energy of motion becomes more dispersed. As you'll see shortly, "dispersed" means spread over more quantized energy levels.

Phase changes lead from a solid, in which particle motion is restricted, to a liquid, in which the particles have more freedom to move around each other, to a gas, with its much greater freedom of particle motion. Along with this greater freedom of motion, the energy of the particles becomes dispersed over more levels. Dissolving a salt leads from a crystalline solid and pure liquid to ions and solvent molecules moving and interacting throughout the solution; their energy of motion, therefore, is much more dispersed. In the chemical reactions shown above, fewer moles of crystalline solids produce more moles of gases and/or solvated ions. In these cases, there is not only more freedom of motion, but more particles to disperse their energy over more levels.

A

B
Figure 20.1 A spontaneous endothermic chemical reaction. $A$, When the crystalline solid reactants barium hydroxide octahydrate and ammonium nitrate are mixed, a slurry soon forms as waters of hydration are released. B, The reaction mixture absorbs heat so quickly from the surroundings that the beaker becomes covered with frost, and a moistened block of wood freezes to it.

Thus, in each process, the particles have more freedom of motion and, therefore, their energy of motion has more levels over which to be dispersed:
less freedom of particle motion $\longrightarrow$ more freedom of particle motion
localized energy of motion $\longrightarrow$ dispersed energy of motion
Phase change:
solid $\longrightarrow$ liquid $\longrightarrow$ gas
Dissolving of salt: crystalline solid + liquid $\longrightarrow$ ions in solution
Chemical change: crystalline solids $\longrightarrow$ gases + ions in solution
In thermodynamic terms, a change in the freedom of motion of particles in a system, that is, in the dispersal of their energy of motion, is a key factor determining the direction of a spontaneous process.

## Entropy and the Number of Microstates

Let's see how freedom of motion and dispersal of energy relate to spontaneous change. In earlier chapters, we discussed the quantization of energy, not just quantized electronic energy levels of an atom or molecule, but also quantized kinetic energy levels-vibrational, rotational, and translational-of a molecule and its atoms (see Tools of the Laboratory, p. 357).

Picture a system of, say, 1 mol of $\mathrm{N}_{2}$ gas and focus on one molecule. At any instant, it is moving through space (translating) at a specific speed, it is rotating at a specific frequency, and its atoms are vibrating at a specific frequency. In the next instant, the molecule collides with another or with the container, and these motional (kinetic) energy states change to different values. The complete quantum state of the molecule at any instant is given by these specific electronic, translational, rotational, and vibrational states.

Each quantized state of the whole system of molecules is called a microstate, and at any one instant, the total energy of the system is dispersed throughout one niensate Th thext instant, theehergye for the system is dispersed throughout a different microstate. Many quantum states are possible for a single molecule, and the number of microstates possible for the system of 1 mol of molecules is staggering-on the order of $10^{10^{23}}$. At a given set of conditions, each microstate has the same total energy as any other. Therefore, each microstate is equally possible for the system, and the laws of probability say that, over time, all microstates are equally likely. If we focus only on microstates associated with thermal energy (that is, not electron energy states), the number of microstates for a system is the number of ways it can disperse its thermal (kinetic) energy among the various modes of motion of all its molecules.

In 1877, the Austrian mathematician and physicist Ludwig Boltzmann related the number of microstates $(W)$ to the entropy $(\boldsymbol{S})$ of the system:

$$
\begin{equation*}
S=k \ln W \tag{20.1}
\end{equation*}
$$

where $k$, the Boltzmann constant, is the universal gas constant $(R)$ divided by Avogadro's number $\left(N_{\mathrm{A}}\right)$, or $R / N_{\mathrm{A}}$, and equals $1.38 \times 10^{-23} \mathrm{~J} / \mathrm{K}$. The term $W$ is just a number of microstates, so it has no units; therefore, $S$ has units of joules/kelvin $(\mathrm{J} / \mathrm{K})$. The system has its total energy in only one microstate at any one instant; therefore, the total number of microstates possible defines the extent of energy dispersal and, thus, entropy. Thus,

- A system with fewer microstates (smaller $W$ ) has lower entropy (lower $S$ ).
- A system with more microstates (larger $W$ ) has higher entropy (higher $S$ ).

For our earlier examples,
lower entropy (fewer microstates) $\longrightarrow$ higher entropy (more microstates)
Phase change: $\quad$ solid $\longrightarrow$ liquid $\longrightarrow$ gas
Dissolving of salt: crystalline solid + liquid $\longrightarrow$ ions in solution
Chemical change: crystalline solids $\longrightarrow$ gases + ions in solution
(In Chapter 13, we used some of these ideas to explain solution behavior.)

Changes in Entropy If a physical or chemical change results in a greater number of microstates, there are more ways to disperse the energy of the system. Thus, the entropy increases:

$$
S_{\text {more microstates }}>S_{\text {fewer microstates }}
$$

If the change results in a lower number of microstates, the entropy decreases.
Like internal energy $(E)$ and enthalpy $(H)$, entropy is a state function and, thus, depends only on the present state of the system, not on the path it took to arrive at that state (see Chapter 6, p. 241). Therefore, the change in entropy of the system ( $\Delta S_{\text {sys }}$ ) depends only on the difference between its final and initial values:

$$
\Delta S_{\mathrm{sys}}=S_{\text {final }}-S_{\text {initial }}
$$

Like any state function, $\Delta S_{\text {sys }}>0$ when its value increases during a change. For example, when dry ice sublimes to gaseous carbon dioxide, we have

$$
\mathrm{CO}_{2}(s) \longrightarrow \mathrm{CO}_{2}(g) \quad \Delta S_{\text {sys }}=S_{\text {final }}-S_{\text {initial }}=S_{{\text {gaseous } \mathrm{CO}_{2}}-S_{\mathrm{solid} \mathrm{CO}_{2}}>0}>0
$$

Similarly, $\Delta S_{\text {sys }}<0$ means the entropy decreases during a change, as when water vapor condenses:

$$
\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta S_{\text {sys }}=S_{\text {liquid } \mathrm{H}_{2} \mathrm{O}}-S_{\text {gaseous } \mathrm{H}_{2} \mathrm{O}}<0
$$

Or, consider the decomposition of dinitrogen tetraoxide (written as $\mathrm{O}_{2} \mathrm{~N}-\mathrm{NO}_{2}$ ):

$$
\mathrm{O}_{2} \mathrm{~N}-\mathrm{NO}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)
$$

When the $\mathrm{N}-\mathrm{N}$ bond in 1 mol of dinitrogen tetraoxide molecules breaks, the 2 mol of $\mathrm{NO}_{2}$ molecules have many more available rotational, vibrational, and translational motions; thus, in any given instant, their energy disperses throughout any one of a greater number of microstates:

$$
\Delta S_{\text {sys }}=\Delta S_{\mathrm{rxn}}=S_{\text {final }}-S_{\text {initial }}=S_{\text {products }}-S_{\text {reactants }}=2 S_{\mathrm{NO}_{2}}-S_{\mathrm{N}_{2} \mathrm{O}_{4}}>0
$$

Quantitative Meaning of an Entropy Change Tyo approaches for quantifying
 approach based on the number of microstates possible for a system at any given instant. The second is based on the heat absorbed (or released) by the system. We'll explore both for a system of 1 mol of a gas expanding from 1 L to 2 L and behaving ideally, much as neon does at 298 K :

1 mol neon (initial: 1 L and 298 K ) $\longrightarrow 1$ mol neon (final: 2 L and 298 K )

1. The approach based on number of microstates. We use this approach to find $\Delta S_{\text {sys }}$ by applying Equation 20.1. Figure 20.2 shows a container consisting of two identical flasks connected by a stopcock, with 1 mol of neon in the left flask and an evacuated right flask. We know that when we open the stopcock, the gas will expand to fill both flasks to 0.5 mol each—but why? Opening the stopcock increases the volume, which increases the number of translational energy levels available as it increases the number of particle locations. As a result, the particles will occupy more energy levels, so the number of possible microstatesand the entropy-increases.

Figure 20.3 presents this idea with particles on energy levels in a box of changeable volume. Note that when the stopcock opens, there are more energy levels, and they are closer together, so more distributions of particles are possible.

Figure 20.3 The entropy increase due to expansion of a gas. The energy levels available to a group of 21 gas particles are depicted as horizontal lines in a vertical box of narrow width. Each distribution of energies for the 21 particles represents one microstate. When the stopcock is opened, the volume increases, as indicated by the wider box on the right, and the particles have more freedom of motion and more energy levels available. At constant temperature, the total energy of the particles remains constant, but their energy has more ways to be distributed, so there are more microstates possible, and the entropy increases.

In Figure 20.4, we symbolically represent the number of microstates by the locations of particles in two attached flasks. Let's start with one neon atom and think through what happens as we add more atoms to the system, and open the stopcock. At a given instant, an atom in the left flask has its energy in one of some number ( $W$ ) of possible microstates, and it has the same number possible in the right flask. Opening the stopcock increases the volume, which increases the number of possible locations and translational energy levels. As a result, the system has $2^{1}$, or 2 times as many microstates available when the atom moves through both flasks (final state, $W_{\text {final }}$ ) as when it is confined to one (initial state, $W_{\text {initial }}$ ).

With more atoms, different sets of them can occupy various energy levels, and each distribution of occupied levels represents a microstate. Thus, as Figure 20.4 shows for two atoms, A and B, moving through both flasks, there are $2^{2}$, or 4 , times as many alternative microstates as when they are confined initially to one flask-some number of microstates with A and B in the left, the same number with A in the left and B in the right, that number with B in the left and A in the right, and that number with A and B in the right. Add another atom, and there are $2^{3}$, or 8 , times as many alternative microstates when the stopcock is open. With 10 Ne atoms, there are $2^{10}$, or 1024 , times as many microstates possible for the gas in both flasks. Finally, with $1 \mathrm{~mol}\left(N_{\mathrm{A}}\right)$ of Ne , there are $2^{N_{\mathrm{A}}}$ times as many microstates possible for the atoms in the larger volume ( $W_{\text {final }}$ ) as in the smaller ( $W_{\text {initial }}$ ). Thus, for 1 mol , we have

$$
\frac{W_{\text {final }}}{W_{\text {initial }}}=2^{N_{\mathrm{A}}}
$$

Now let's find $\Delta S_{\text {sys }}$ through the Boltzmann equation, $S=k \ln W$. From the properties of logarithms (Appendix A), we know that $\ln A-\ln B=\ln A / B$. Thus,

Figure 20.4 Expansion of a gas and the increase in number of microstates.
When a gas confined to one flask is allowed to spread through two flasks, the energy of the system of particles is dispersed over more microstates, and so the entropy is higher. Each set of locations of particles in the available volume symbolically represents a different microstate. When the volume increases, the number of possible microstates increases by a factor of $2^{n}$, where $n$ is the number of particles.

RELATIVE NUMBER OF MICROSTATES, $W$

2 atoms

3 atoms

> 10 atoms
> $6 \times 10^{23}$ atoms

Also, from Appendix $\mathrm{A}, \ln A^{y}=y \ln A$; thus, with $k=R / N_{\mathrm{A}}$, we have

$$
\begin{aligned}
\Delta S_{\text {sys }} & =\frac{R}{N_{\mathrm{A}}} \ln 2^{N_{\mathrm{A}}}=\left(\frac{R}{N_{\mathrm{A}}}\right) N_{\mathrm{A}} \ln 2=R \ln 2 \\
& =(8.314 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})(0.693)=5.76 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K}
\end{aligned}
$$

2. The approach based on heat changes. As you know, when a sample of gas is heated, it expands. Let's compare the entropy change we found from the statistical approach-a gas expanding into a vacuum-to the entropy change that occurs when a gas is heated and does work on the surroundings. This approach for finding the entropy change uses the relationship

$$
\begin{equation*}
\Delta S_{\mathrm{sys}}=\frac{q_{\mathrm{rev}}}{T} \tag{20.2}
\end{equation*}
$$

where $T$ is the temperature at which the heat change occurs and $q$ is the heat absorbed. The subscript "rev" refers to a reversible process, one that occurs slowly enough for equilibrium to be maintained, so that the direction of the change can be reversed by an infinitesimal reversal of conditions.

We can approximate the reversible expansion of the same sample of neon gas by placing it in a piston-cylinder assembly surrounded by a heat reservoir to maintain constant temperature, and confining the gas by the "pressure" of a beaker of sand resting on the piston (Figure 20.5). We remove one grain of sand (an "infinitesimal" change in pressure) with a pair of tweezers, and the gas expands a tiny amount, raising the piston and doing work, $-w$. If the neon behaves ideally, it absorbs from the heat reservoir a tiny increment of heat $q$, equivalent to $-w$. We remove another grain of sand, and the gas expands a tiny bit more and absorbs another tiny increment of heat. This expansion is very close to being reversible because we can reverse it at any point by putting a grain of sand back into the beaker, which equses Giny quantity df Norkaonecy the surroundings compressing the gas and a tiny release of heat into the reservoir. If we continue this expansion process to 2 L and apply calculus through the process of integration, which adds together all the tiny increments of heat, we find $q_{\text {rev }}$ is 1718 J . Thus, applying Equation 20.2, the entropy change is

$$
\Delta S_{\mathrm{sys}}=\frac{q_{\mathrm{rev}}}{T}=\frac{1718 \mathrm{~J}}{298 \mathrm{~K}}=5.76 \mathrm{~J} / \mathrm{K}
$$

Notice that this is the same value we obtained previously. That first approach, which is often limited to simple systems like ideal gases, shows how a system's entropy changes when the volume occupied by the particles increases, and it allows us to visualize the changes in terms of energy dispersal. This second approach, which involves incremental heat changes, is not as easy to visualize, but is applicable to more complex systems.

## Entropy and the Second Law of Thermodynamics

Now back to our earlier question: what criterion determines the direction of a spontaneous process? The change in entropy is the key, but to evaluate that change correctly, we must consider more than just the system. After all, some processes, such as ice melting or a crystal dissolving, occur spontaneously, and the system ends up with higher entropy; other processes, such as water freezing or a crystal forming, occur spontaneously, and the system ends up with lower entropy. But if we consider changes in both the system and its surroundings, we find that all real processes occur spontaneously in the direction that increases the entropy of the universe (system plus surroundings). This is one way to state the second law of thermodynamics.

The second law places no limitations on the entropy change of the system or the surroundings: either may be negative; that is, either system or surroundings may have lower entropy after the process. The law does state, however, that for

Figure 20.5 A "reversible" change.
At constant temperature, changing the pressure by tiny increments approximates a reversible change in volume. Remove a grain of sand, and the gas does a tiny quantity of work, $-w$, to the surroundings and absorbs a tiny quantity of heat, $q$. The sum of all the quantities of heat divided by $T$ is the change in entropy.
a spontaneous process, the sum of the entropy changes must be positive. If the entropy of the system decreases, the entropy of the surroundings must increase even more to offset the system's decrease, so that the entropy of the universe (system plus surroundings) increases. A quantitative statement of the second law is, for any real spontaneous process,

$$
\begin{equation*}
\Delta S_{\text {univ }}=\Delta S_{\text {sys }}+\Delta S_{\text {surr }}>0 \tag{20.3}
\end{equation*}
$$

## Standard Molar Entropies and the Third Law

Both entropy and enthalpy are state functions, but the nature of their values differs in a fundamental way. Recall that we cannot determine absolute enthalpies because we have no easily measurable starting point, no baseline value for the enthalpy of a substance. Therefore, we measure only enthalpy changes.

In contrast, we can determine the absolute entropy of a substance. To do so, we apply the third law of thermodynamics, which states that a perfect crystal has zero entropy at a temperature of absolute zero: $S_{\text {sys }}=0$ at 0 K . "Perfect" means that all the particles are aligned flawlessly in the crystal structure, with no defects of any kind. At absolute zero, all particles in the crystal have the minimum energy, so there is only one microstate, only one way the energy can be dispersed: thus, in Equation 20.1, $W=1$, so $S=k \ln 1=0$. When we warm the crystal, its total energy increases and thus can be dispersed into more than one microstate. Thus, $W>1$, $\ln W>0$, and $S>0$.

To obtain a value for $S$ at a given temperature, we first cool a crystalline sample of the substance as close to 0 K as possible. Then we heat it in small increments, dividing $q$ by $T$ to get the increase in $S$ for each increment, and add up all the entropy increases to the temperature of interest, usually 298 K . The entropy of a substance at a given temperature is therefore an absolute value that is equal tofte entropy inerease obfinednuen thesubstance is heated from 0 K to that temperature.

As with other thermodynamic variables, we usually compare entropy values for substances in their standard states at the temperature of interest: 1 atm for gases, 1 M for solutions, and the pure substance in its most stable form for solids or liquids. Because entropy is an extensive property, that is, one that depends on the amount of substance, we are interested in the standard molar entropy ( $S^{\circ}$ ) in units of $\mathrm{J} / \mathrm{mol} \cdot \mathrm{K}\left(\mathrm{or}_{\mathrm{Jmol}}{ }^{-1} \mathrm{~K}^{-1}\right.$ ). The $S^{\circ}$ values at 298 K for many elements, compounds, and ions appear, with other thermodynamic variables, in Appendix B.
Predicting Relative $\boldsymbol{S}^{\circ}$ Values of a System Based on an understanding of systems at the molecular level and the effects of heat absorbed, we can see how the entropy of a substance is affected by conditions. Let's consider the effects of temperature, the most fundamental condition, and also physical state, dissolution, and atomic or molecular complexity. (All $S^{\circ}$ values in the following discussion have units of $\mathrm{J} / \mathrm{mol} \cdot \mathrm{K}$ and, unless stated otherwise, refer to the system at 298 K .)

1. Temperature changes. For a given substance, $S^{\circ}$ increases as the temperature rises. Consider these typical values for copper metal:

| $T(\mathrm{~K}):$ | 273 | 295 | 298 |
| :--- | :--- | :--- | :--- |
| $S^{\circ}:$ | 31.0 | 32.9 | 33.2 |

The temperature increases as heat is absorbed $(q>0)$, which represents an increase in the average kinetic energy of the particles. Recall from Figure 5.14 (p. 211) that the kinetic energies of gas particles are distributed over a range, which becomes wider as the temperature rises, and a similar behavior holds for liquids and solids. With more microstates available in which the energy can be dispersed at any instant, the entropy of the substance goes up. In other words, raising the temperature allows more possible microstates. Figure 20.6 provides three ways to view the effect of temperature on entropy.

Figure 20.6 Visualizing the effect of temperature on entropy. A, These computer simulations show the paths of particle centers in a crystal. At any $T>0 \mathrm{~K}$, each particle moves about its lattice position: the higher the temperature, the greater the movement. Adding heat increases the total energy. Therefore, the particles have greater freedom of motion, and their energy is more dispersed; thus, the entropy increases. B, At any $T$, there is a range of occupied energy levels and, thus, a certain number of available microstates. As heat is added, the
total energy increases, and the range of occupied energy levels becomes greater: lower $T$ means fewer microstates (lower S); higher $T$ means more microstates (higher S). C, The energy levels available to a group of 21 gas particles are shown as horizontal lines in a vertical box of fixed width. The height of the box represents the total energy and number of energy levels available: at lower $T$, the box is short, and at higher $T$, it is tall. Thus, when heat is added, the total energy increases and becomes more dispersed, so entropy increases.

Figure 20.7 The increase in entropy from solid to liquid to gas. A plot of entropy vs. temperature for $\mathrm{O}_{2}$ includes selected entropy values (in $\mathrm{J} / \mathrm{mol} \cdot \mathrm{K}$ ). Note the gradual increase in entropy within a phase and the abrupt increase at a phase change. The molecular-scale views depict the increase in freedom of motion as the solid melts and, even more so, as the liquid vaporizes.

Figure 20.8 The entropy change accompanying the dissolution of a salt. When a crystalline salt and liquid water form a solution, the entropy change has two contributions: a positive contribution as the crystal separates into ions and the pure liquid disperses them, and a negative contribution as water molecules become organized around each ion. The relative magnitudes of these contributions determine the overall entropy change. The entropy of a salt solution is usually greater than that of the solid and water.

2. Physical states and phase changes. For a phase change such as melting or vaporizing, heat is absorbed $(q>0)$. The particles have more freedom of motion and their energy is more dispersed, so the entropy change is positive. Thus, $S^{\circ}$ increases for a substance as it changes from a solid to a liquid to a gas:

Figure 20.7 shows how the entropy of molecular oxygen changes as it is heated from solid to liquid to gas, and the behavior of $\mathrm{O}_{2}$ is typical of many other substances. Note the gradual increase within a phase as the temperature rises and the large, sudden increase at the phase change. Particles in the solid vibrate about their positions but, on average, remain fixed. The energy of the solid has the fewest microstates available and, thus, the least dispersed energy and the lowest entropy. As the temperature rises, the entropy gradually increases with the increase in the particles' kinetic energy. When the solid melts, the particles move much more freely between and around each other, so there is an abrupt increase in entropy. Further heating increases the speed of the particles in the liquid, and the entropy increases gradually. Finally, the particles undergo another, and much larger, abrupt entropy increase as a gas. That is, the increase in entropy from liquid to gas is much larger than that from solid to liquid: $\Delta S_{\text {vap }}^{\circ} \gg \Delta S_{\text {fus }}^{\circ}$.
3. Dissolving a solid or liquid. The entropy of a dissolved molecular solid or liquid is greater than the entropy of the pure solute. For ionic solutes, however, the nature of solute and solvent affects the overall change:

|  | NaCl | $\mathrm{AlCl}_{3}$ | $\mathrm{CH}_{3} \mathrm{OH}$ |
| :--- | :---: | :---: | :--- |
| $S^{\circ}(s$ or $l):$ | $72.1(s)$ | $167(s)$ | $127(l)$ |
| $S^{\circ}(a q):$ | 115.1 | -148 | 132 |

When an ionic solid dissolves in water, the crystal breaks down, and the ions experience a great increase in freedom of motion as they separate, with their energy dispersed into more possible microstates. We expect the entropy of the ions themselves to be greater in the solution than in the crystal. However, some of the water molecules become arranged around the ions (Figure 20.8), which limits

their freedom of motion (see Figure 13.2, p. 503). In fact, for small, multiply charged ions, some solvent molecules become so organized around the ions that their energy of motion becomes less dispersed. This negative portion of the total entropy change can lead to negative $S^{\circ}$ values for the ions in solution. For example, in the case of $\mathrm{AlCl}_{3}$ above, the $\mathrm{Al}^{3+}(a q)$ ion has such a negative $S^{\circ}$ value $(-313 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{K})$ that when $\mathrm{AlCl}_{3}$ dissolves in water, even though $S^{\circ}$ of $\mathrm{Cl}^{-}(a q)$ is positive, the overall entropy of aqueous $\mathrm{AlCl}_{3}$ is lower than that of solid $\mathrm{AlCl}_{3}$.*

For molecular solutes, the increase in entropy upon dissolving is typically much smaller than for ionic solutes. After all, for a solid such as glucose, there is no separation into ions, and for a liquid such as methanol or ethanol (Figure 20.9), the breakdown of a crystal structure is absent as well. Furthermore, in these small alcohols and in pure water, the molecules form many H bonds, so there is relatively little change in their freedom of motion when they are mixed. The small increase in the entropy of dissolved methanol or ethanol arises from the separation of identical molecules from eachrothegiothe Pure Folufe maitwater when the molecules are mixed.
4. Dissolving a gas. The particles in a gas already have so much freedom of motion-and, thus, such highly dispersed energy-that they lose some when they dissolve in a liquid or solid. Therefore, the entropy of a solution of a gas in a liquid or in a solid is always less than the entropy of the gas itself. For instance, when gaseous $\mathrm{O}_{2}\left[S^{\circ}(g)=205.0 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{K}\right]$ dissolves in water, its entropy decreases dramatically $\left[S^{\circ}(a q)=110.9 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{K}\right]$ (Figure 20.10). When a gas dissolves in another gas, however, the entropy increases as a result of the separation and mixing of the molecules.
5. Atomic size or molecular complexity. In general, differences in entropy values for substances in the same phase are based on atomic size and molecular complexity. Within a periodic group, energy levels become closer together for heavier atoms, which means the number of possible microstates, and thus molar entropy, increases down the group:

|  | Li | Na | K | Rb | Cs |
| ---: | :--- | :--- | :--- | :--- | :--- |
| Atomic radius $(\mathrm{pm}):$ | 152 | 186 | 227 | 248 | 265 |
| Molar mass $(\mathrm{g} / \mathrm{mol}):$ | 6.941 | 22.99 | 39.10 | 85.47 | 132.9 |
| $S^{\circ}(s):$ | 29.1 | 51.4 | 64.7 | 69.5 | 85.2 |

The same trend of increasing entropy down a group holds for similar compounds:

|  | HF | HCl | HBr | HI |
| ---: | :---: | :---: | :---: | :---: |
| Molar mass $(\mathrm{g} / \mathrm{mol}):$ | 20.01 | 36.46 | 80.91 | 127.9 |
| $S^{\circ}(\mathrm{g}):$ | 173.7 | 186.8 | 198.6 | 206.3 |

[^31]Figure 20.9 The small increase in entropy when ethanol dissolves in water. Pure ethanol ( $\mathbf{A}$ ) and pure water (B) have many intermolecular H bonds. $\mathbf{C}$, In a solution of these two substances, the molecules form H bonds to one another, so their freedom of motion does not change significantly. Thus, the entropy increase is relatively small and is due mostly to identical molecules being separated and intermixed.

Figure 20.10 The large decrease in entropy of a gas when it dissolves in a liquid. The wide range of motion and high entropy of molecules of $\mathrm{O}_{2}$ are reduced greatly when the gas dissolves in water.

For an element that occurs in different forms (allotropes), the entropy is higher in the form that allows the atoms more freedom of motion, which disperses their energy because there are more microstates. For example, the $S^{\circ}$ of graphite is $5.69 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{K}$, whereas the $S^{\circ}$ of diamond is $2.44 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{K}$. In diamond, covalent bonds extend in three dimensions, allowing the atoms little movement; in graphite, covalent bonds extend only within a two-dimensional sheet, and motion of the sheets relative to each other is relatively easy.

For compounds, entropy increases with chemical complexity, that is, with the number of atoms in a formula unit or molecule of the compound. This trend holds for both ionic and covalent substances, as long as they are in the same phase:

|  | NaCl | $\mathrm{AlCl}_{3}$ | $\mathrm{P}_{4} \mathrm{O}_{10}$ | NO | $\mathrm{NO}_{2}$ | $\mathbf{N}_{2} \mathbf{O}_{4}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| $S^{\circ}(\mathrm{s}):$ | 72.1 | 167 | 229 |  |  |  |
| $S^{\circ}(\mathrm{g}):$ |  |  |  | 211 | 240 | 304 |

The trend is based on the types of movement, and thus number of microstates, possible for the atoms (or ions) in each compound. For example, among the nitrogen oxides listed above, the two atoms of NO can vibrate only toward and away from each other. The three atoms of $\mathrm{NO}_{2}$ have more vibrational motions, and the six atoms of $\mathrm{N}_{2} \mathrm{O}_{4}$ have even more (Figure 20.11; see also Figure B9.1, p. 357).

Figure 20.11 Entropy and vibrational motion. A diatomic molecule, such as NO , can vibrate in only one way. $\mathrm{NO}_{2}$ can vibrate in more ways, and $\mathrm{N}_{2} \mathrm{O}_{4}$ in even more. Thus, as the number of atoms increases, there is more freedom of motion and there are more possible microstates into which a molecule can disperse its vibrational energy, so it has higher entropy.

For larger molecules, we also consider how one part of a molecule moves relative to other parts. A long hydrocarbon chain can rotate and vibrate in more ways than a short one, so entropy increases with chain length. A ring compound, such as cyclopentane $\left(\mathrm{C}_{5} \mathrm{H}_{10}\right)$, has lower entropy than the corresponding chain compound, pentene $\left(\mathrm{C}_{5} \mathrm{H}_{10}\right)$, because the ring structure restricts freedom of motion:

|  | $\mathrm{CH}_{4}(g)$ | $\mathrm{C}_{2} \mathrm{H}_{6}(g)$ | $\mathrm{C}_{3} \mathrm{H}_{8}(g)$ | $\mathrm{C}_{4} \mathrm{H}_{10}(g)$ | $\mathrm{C}_{5} \mathrm{H}_{10}(g)$ | $\mathrm{C}_{5} \mathrm{H}_{10}(\mathrm{cyclo}, g)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)$ |  |  |  |  |  |  |
| 186 | 230 | 270 | 310 | 348 | 293 | 161 |

Remember, these trends hold only for substances in the same physical state. Gaseous methane $\left(\mathrm{CH}_{4}\right)$ has higher entropy than liquid ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$, even though ethanol molecules are more complex. When gases are compared with liquids, the effect of physical state usually dominates that of molecular complexity.

## SAMPLE PROBLEM 20.1 Predicting Relative Entropy Values

PROBLEM Choose the member with the higher entropy in each of the following pairs, and justify your choice [assume constant temperature, except in part (e)]:
(a) 1 mol of $\mathrm{SO}_{2}(g)$ or 1 mol of $\mathrm{SO}_{3}(g)$
(b) 1 mol of $\mathrm{CO}_{2}(s)$ or 1 mol of $\mathrm{CO}_{2}(g)$
(c) 3 mol of $\mathrm{O}_{2}(\mathrm{~g})$ or 2 mol of $\mathrm{O}_{3}(\mathrm{~g})$
(d) 1 mol of $\operatorname{KBr}(s)$ or 1 mol of $\operatorname{KBr}(a q)$
(e) Seawater at $2^{\circ} \mathrm{C}$ or at $23^{\circ} \mathrm{C}$
(f) 1 mol of $\mathrm{CF}_{4}(\mathrm{~g})$ or 1 mol of $\mathrm{CCl}_{4}(\mathrm{~g})$

PLAN In general, we know that particles with more freedom of motion have more microstates into which to disperse their kinetic energy, so they have higher entropy, and that raising the temperature increases entropy. We apply the general categories described in the text to choose the member with the higher entropy.
SOLUTION (a) 1 mol of $\mathrm{SO}_{3}(\mathrm{~g})$. For equal numbers of moles of substances with the same types of atoms in the same physical state, the more atoms in the molecule, the more types of motion available, and thus the higher the entropy.
(b) 1 mol of $\mathrm{CO}_{2}(g)$. For a given substance, entropy increases in the sequence $s<l<g$.
(c) 3 mol of $\mathrm{O}_{2}(\mathrm{~g})$. The two samples contain the same number of oxygen atoms but different numbers of molecules. Despite the greater complexity of $\mathrm{O}_{3}$, the greater number of molecules dominates in this case because there are many more microstates possible for three moles of particles than for two moles.
(d) 1 mol of $\mathrm{KBr}(a q)$. The two samples have the same number of ions, but their motion is more limited and their energy less dispersed in the solid than in the solution.
(e) Seawater at $23^{\circ} \mathrm{C}$. Entropy increases with rising temperature.
(f) 1 mol of $\mathrm{CCl}_{4}(g)$. For similar compounds, entropy increases with molar mass.

FOLLOW-UP PROBLEM 20.1 For 1 mol of substance at a given temperature, select the member with the higher entropy in each of the following pairs, and give the reason for your choice:
(a) $\mathrm{PCl}_{3}(g)$ or $\mathrm{PCl}_{5}(g)$
(b) $\mathrm{CaF}_{2}(s)$ or $\mathrm{BaCl}_{2}(s)$
(c) $\mathrm{Br}_{2}(g)$ or $\mathrm{Br}_{2}(l)$

## Section Summary

A change is spontaneous under specified conditions if it occurs without a continuous input of energy. - Neither the first law of thermodynamics nor the sign of $\Delta H$ predicts the direction of a spontaneous change. All spontaneous processes involve_an increase in the dispersion of energy. - Entropy is a state function that measures the extent of energy dispersal into the number of microstates possible for a system, which is related to the freedom of motion of its particles. - The second law of thermodynamics states that, in a spontaneous process, the entropy of the universe (system plus surroundings) increases. - Absolute entropy values can be found because perfect crystals have zero entropy at 0 K (third law). • Standard molar entropy, $S^{\circ}(\mathrm{J} / \mathrm{mol} \cdot \mathrm{K})$, is affected by temperature, phase changes, dissolution, and atomic size or molecular complexity.

### 20.2 CALCULATING THE CHANGE IN ENTROPY OF A REACTION

In addition to understanding trends in $S^{\circ}$ values for different substances or for the same substance in different phases, chemists are especially interested in learning how to predict the sign and calculate the value of the entropy change that occurs during a reaction.

## Entropy Changes in the System: Standard Entropy of Reaction ( $\Delta S_{\mathrm{rxn}}^{\circ}$ )

Based on the ideas we just discussed, we can often predict the sign of the standard entropy of reaction, $\Delta S_{\mathbf{r x n}}^{\circ}$, the entropy change that occurs when all reactants and products are in their standard states. A deciding event is usually a change in the number of moles of gas. Because gases have such great freedom of motion and thus high molar entropies, if the number of moles of gas increases, $\Delta S_{\mathrm{rxn}}^{\circ}$ is usually positive; if the number decreases, $\Delta S_{\mathrm{rxn}}^{\circ}$ is usually negative.

For example, when $\mathrm{H}_{2}(g)$ and $\mathrm{I}_{2}(s)$ form $\mathrm{HI}(g)$, the total number of moles of substance stays the same, but we predict that the entropy increases because the number of moles of gas increases:

$$
\mathrm{H}_{2}(g)+\mathrm{I}_{2}(s) \longrightarrow 2 \mathrm{HI}(g) \quad \Delta S_{\mathrm{rxn}}^{\circ}=S_{\text {products }}^{\circ}-S_{\text {reactants }}^{\circ}>0
$$

When ammonia forms from its elements, 4 mol of gas produces 2 mol of gas, so we predict that the entropy decreases:

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g) \quad \Delta S_{\mathrm{rxn}}^{\circ}=S_{\text {products }}^{\circ}-S_{\text {reactants }}^{\circ}<0
$$

Sometimes, even when the amount (mol) of gases stays the same, another factor related to freedom of motion may help predict the sign of the entropy change. For example, when cyclopropane is heated to $500^{\circ} \mathrm{C}$, the ring opens and propene forms. The chain has more freedom of motion than the ring, so the standard molar entropy of the product is greater than that of the reactant:

Keep in mind, however, that in general we cannot predict the sign of the entropy change unless the reaction involves a change in number of moles of gas.

Recall that by applying Hess's law (Chapter 6), we can combine $\Delta H_{\mathrm{f}}^{\circ}$ values to find the standard heat of reaction, $\Delta H_{\mathrm{rxn}}^{\circ}$. Similarly, we combine $S^{\circ}$ values to find the standard entropy of reaction, $\Delta S_{\mathrm{rxn}}^{\circ}$ :

$$
\begin{equation*}
\Delta S_{\mathrm{rxn}}^{\circ}=\Sigma m S_{\text {products }}^{\circ}-\Sigma n S_{\text {reactants }}^{\circ} \tag{20.4}
\end{equation*}
$$

where $m$ and $n$ are the amounts (mol) of the individual species, given by their coefficients in the balanced equation. For the formation of ammonia, we have the following:

```
From Appendix B, we find the appropriate \(S^{\circ}\) values:
```

$$
\begin{aligned}
\Delta S_{\mathrm{rxn}}^{\circ} & =[(2 \mathrm{~mol})(193 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})]-[(1 \mathrm{~mol})(191.5 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})+(3 \mathrm{~mol})(130.6 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})] \\
& =-197 \mathrm{~J} / \mathrm{K}
\end{aligned}
$$

As we predicted from the decrease in number of moles of gas, $\Delta S_{\mathrm{rxn}}^{\circ}<0$.

## SAMPLE PROBLEM 20.2 Calculating the Standard Entropy of Reaction, $\Delta S_{\text {rxn }}^{\circ}$

PROBLEM Calculate $\Delta S_{\mathrm{rxn}}^{\circ}$ for the combustion of 1 mol of propane at $25^{\circ} \mathrm{C}$ :

$$
\mathrm{C}_{3} \mathrm{H}_{8}(g)+5 \mathrm{O}_{2}(g) \longrightarrow 3 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

PLAN To determine $\Delta S_{\mathrm{rxn}}^{\circ}$, we apply Equation 20.4. We predict the sign of $\Delta S_{\mathrm{rxn}}^{\circ}$ from the change in the number of moles of gas: 6 mol of gas yields 3 mol of gas, so the entropy will probably decrease $\left(\Delta S_{\mathrm{rxn}}^{\circ}<0\right)$.
SOLUTION Calculating $\Delta S_{\text {rxn }}^{\circ}$. Using Appendix B values,

$$
\begin{aligned}
& \Delta S_{\mathrm{rxn}}^{\circ}=\left[\left(3 \mathrm{~mol} \mathrm{CO}_{2}\right)\left(S^{\circ} \text { of } \mathrm{CO}_{2}\right)+\left(4 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}\right)\left(S^{\circ} \text { of } \mathrm{H}_{2} \mathrm{O}\right)\right] \\
& -\left[\left(1 \mathrm{~mol} \mathrm{C}_{3} \mathrm{H}_{8}\right)\left(S^{\circ} \text { of } \mathrm{C}_{3} \mathrm{H}_{8}\right)+\left(5 \mathrm{~mol} \mathrm{O}_{2}\right)\left(\mathrm{S}^{\circ} \text { of } \mathrm{O}_{2}\right)\right] \\
& =[(3 \mathrm{~mol})(213.7 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})+(4 \mathrm{~mol})(69.9 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})] \\
& -[(1 \mathrm{~mol})(269.9 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})+(5 \mathrm{~mol})(205.0 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})] \\
& =-374 \mathrm{~J} / \mathrm{K}
\end{aligned}
$$

CHECK $\Delta S^{\circ}<0$, so our prediction is correct. Rounding gives [3(200) $+4(70)$ ] -$[270+5(200)]=880-1270=-390$, close to the calculated value.
FOLLOW-UP PROBLEM 20.2 Balance the following equations, predict the sign of $\Delta S_{\mathrm{rxn}}^{\circ}$ if possible, and calculate its value at $25^{\circ} \mathrm{C}$ :
(a) $\mathrm{NaOH}(s)+\mathrm{CO}_{2}(g) \longrightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l)$
(b) $\mathrm{Fe}(s)+\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{Fe}_{2} \mathrm{O}_{3}(s)+\mathrm{H}_{2}(g)$

## Entropy Changes in the Surroundings: The Other Part of the Total

In many spontaneous reactions, such as the synthesis of ammonia and the combustion of propane, we see that the entropy of the reacting system decreases $\left(\Delta S_{\mathrm{rxn}}^{\circ}<0\right)$. The second law dictates that, for a spontaneous process, decreases in the entropy of the system can occur only if increases in the entropy of the surroundings outweigh them. Let's examine the influence of the surroundings-in particular, the addition (or removal) of heat and the temperature at which this heat change occurs-on the total entropy change.

The essential role of the surroundings is to either add heat to the system or remove heat from it. In essence, the surroundings function as an enormous heat source or heat sink, one so large that its temperature remains constant, even though its entropy changes through the loss or gain of heat. The surroundings participate in the two possible types of enthalpy changes as follows:

1. Exothermic change. Heat lost by the system is gained by the surroundings. This heat gain increases the freedom of motion of the particles, which allows their energy to be more dispersed, so the entropy of the surroundings increases:
For an exothermic change: $\quad q_{\text {sys }}<0, \quad q_{\text {surr }}>0$, and $\quad \Delta S_{\text {surr }}>0$
2. Endothermic change. Heat gained by the system is lost by the surroundings. This heat loss reduces the freedom of motion of the particles, which makes their energy less dispersed, so the entropy of the surroundings decreases:

$$
\text { For an endothermic change: } \quad q_{\text {sys }}>0, \quad q_{\text {surr }}<0, \quad \text { and } \quad \Delta S_{\text {surr }}<0
$$

The temperature of the surroundings when the heat is transferred also affects $\Delta S_{\text {surr }}$ Consider the effect of an exothermic reaction at low or high temperature:

- At a lower temperature, such as 20 K , there is very little random motion in the surroundings and, thus, relativelydingenerge This means liererare fewer energy levels in each microstate, and fewer available microstates, in which to disperse the energy. Therefore, transferring heat to the surroundings has a large effect on how much the energy is dispersed.
- At a higher temperature, such as 298 K , the surroundings already have a relatively large quantity of energy dispersed. This means there are more energy levels in each microstate, and a greater number of available microstates. Thus, transferring the same amount of heat has a smaller effect on the total dispersal of energy.
In other words, the change in entropy of the surroundings is greater when heat is added at a lower temperature. Putting these ideas together, the change in entropy of the surroundings is directly related to an opposite change in the heat of the system and inversely related to the temperature at which the heat is transferred. Combining these relationships gives an equation that is closely related to Equation 20.2:

$$
\Delta S_{\mathrm{surr}}=-\frac{q_{\mathrm{sys}}}{T}
$$

Recall that for a process at constant pressure, the heat $\left(q_{P}\right)$ is $\Delta H$, so

$$
\begin{equation*}
\Delta S_{\text {surr }}=-\frac{\Delta H_{\text {sys }}}{T} \tag{20.5}
\end{equation*}
$$

Thus, we can calculate $\Delta S_{\text {surr }}$ by measuring $\Delta H_{\text {sys }}$ and the temperature $T$ at which the change takes place.

To restate the central point, if a spontaneous reaction has a negative $\Delta S_{\text {sys }}$ (fewer microstates into which energy is dispersed), $\Delta S_{\text {surr }}$ must be positive enough (many more microstates into which energy is dispersed) for $\Delta S_{\text {univ }}$ to be positive (net more microstates into which energy is dispersed). Sample Problem 20.3 illustrates this situation for one of the reactions we considered earlier.

A Checkbook Analogy for Heating the Surroundings A monetary analogy may clarify the relative sizes of the changes that arise from heating the surroundings at different initial temperatures. If you have $\$ 10$ in your checking account, a $\$ 10$ deposit represents a $100 \%$ increase in your net worth; that is, a given change to a low initial state has a large impact. If, however, you have a $\$ 1000$ balance, a $\$ 10$ deposit represents only a $1 \%$ increase. That is, the same change to a high initial state has a smaller impact.

## SAMPLE PROBLEM 20.3 Determining Reaction Spontaneity

PROBLEM At 298 K , the formation of ammonia has a negative $\Delta S_{\text {sys }}^{\circ}$ :

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \longrightarrow 2 \mathrm{NH}_{3}(g) \quad \Delta S_{\text {sys }}^{\circ}=-197 \mathrm{~J} / \mathrm{K}
$$

Calculate $\Delta S_{\text {univ }}$, and state whether the reaction occurs spontaneously at this temperature. PLAN For the reaction to occur spontaneously, $\Delta S_{\text {univ }}>0$, and so $\Delta S_{\text {surr }}$ must be greater than $+197 \mathrm{~J} / \mathrm{K}$. To find $\Delta S_{\text {surr }}$, we need $\Delta H_{\text {sys }}^{\circ}$, which is the same as $\Delta H_{\mathrm{rxn}}^{\circ}$. We use $\Delta H_{\mathrm{f}}^{\circ}$ values from Appendix B to find $\Delta H_{\mathrm{rxn}}^{\circ}$. Then, we use $\Delta H_{\mathrm{rxn}}^{\circ}$ and the given $T(298 \mathrm{~K})$ to find $\Delta S_{\text {surr }}$. To find $\Delta S_{\text {univ }}$, we add the calculated $\Delta S_{\text {surr }}$ to the given $\Delta S_{\text {sys }}^{\circ}(-197 \mathrm{~J} / \mathrm{K})$. SOLUTION Calculating $\Delta H_{\text {sys }}^{\circ}$ :
$\Delta H_{\mathrm{sys}}^{\circ}=\Delta H_{\mathrm{rxn}}^{\circ}$

$$
\left.\left.\begin{array}{l}
=[(2 \mathrm{~mol} \mathrm{NH}
\end{array} 3\right)(-45.9 \mathrm{~kJ} / \mathrm{mol})\right]-[(3 \mathrm{~mol} \mathrm{H} 2)(0 \mathrm{~kJ} / \mathrm{mol})+(1 \mathrm{~mol} \mathrm{~N} 2)(0 \mathrm{~kJ} / \mathrm{mol})] \quad \text { }=-91.8 \mathrm{~kJ} .
$$

Calculating $\Delta S_{\text {surr }}$ :

$$
\Delta S_{\text {surr }}=-\frac{\Delta H_{\text {sys }}^{\circ}}{T}=-\frac{-91.8 \mathrm{~kJ} \times \frac{1000 \mathrm{~J}}{1 \mathrm{~kJ}}}{298 \mathrm{~K}}=308 \mathrm{~J} / \mathrm{K}
$$

Determining $\Delta S_{\text {univ }}$ :

$$
\Delta S_{\text {univ }}=\Delta S_{\text {sys }}^{\circ}+\Delta S_{\text {surr }}=-197 \mathrm{~J} / \mathrm{K}+308 \mathrm{~J} / \mathrm{K}=111 \mathrm{~J} / \mathrm{K}
$$

$\Delta S_{\text {univ }}>0$, so the reaction occurs spontaneously at 298 K (see figure in margin).
CHECK Rounding to check the math, we have

$$
\begin{aligned}
& \Delta H_{\mathrm{rxn}}^{\circ} \approx 2(-45 \mathrm{~kJ})=-90 \mathrm{~kJ} \\
& \Delta S_{\text {surr }} \approx-(-90,000 \mathrm{~J}) / 300 \mathrm{~K}=300 \mathrm{~J} / \mathrm{K} \\
& \Delta S_{\text {univ }} \approx-200 \mathrm{~J} / \mathrm{K}+300 \mathrm{~J} / \mathrm{K}=100 \mathrm{~J} / \mathrm{K}
\end{aligned}
$$

Given the negative $\Delta H_{\mathrm{rxn}}^{\circ}$, Le Châtelier's principle predicts that low temperature should favor $\mathrm{NH}_{3}$ formation, and so the answer is reasonable (see the Chemical Connections essay on the Haber process, pp. 771-772).
COMMENT 1. Note that $\Delta H^{\circ}$ has units of kJ, whereas $\Delta S$ has units of J/K. Don't forget to convert kJ to J , or you'll introduce a large error.
2. This example highlights the distinction between thermodynamic and kinetic considerations. Even though $\mathrm{NH}_{3}$ forms spontaneously, it does so slowly, and the chemical industry must expend great effort to catalyze the formation at a practical rate.
FOLLOW-UP PROBLEM 20.3 Does the oxidation of $\mathrm{FeO}(s)$ to $\mathrm{Fe}_{2} \mathrm{O}_{3}(s)$ occur spontaneously at 298 K ?

As Sample Problem 20.3 shows, taking the surroundings into account is crucial to determining reaction spontaneity. Moreover, it clarifies the relevance of thermodynamics to biology, as the Chemical Connections essay shows.

## The Entropy Change and the Equilibrium State

For a process spontaneously approaching equilibrium, $\Delta S_{\text {univ }}>0$. When the process reaches equilibrium, there is no longer any force driving it to proceed further and, thus, no net change in either direction; that is, $\Delta S_{\text {univ }}=0$. At that point, any entropy change in the system is exactly balanced by an opposite entropy change in the surroundings:

$$
\text { At equilibrium: } \quad \Delta S_{\text {univ }}=\Delta S_{\text {sys }}+\Delta S_{\text {surr }}=0 \quad \text { or } \quad \Delta S_{\text {sys }}=-\Delta S_{\text {surr }}
$$

For example, let's calculate $\Delta S_{\text {univ }}$ for a phase change. For the vaporizationcondensation of 1 mol of water at $100^{\circ} \mathrm{C}(373 \mathrm{~K})$,

$$
\mathrm{H}_{2} \mathrm{O}(l ; 373 \mathrm{~K}) \rightleftharpoons \mathrm{H}_{2} \mathrm{O}(g ; 373 \mathrm{~K})
$$

First, we find $\Delta S_{\text {univ }}$ for the forward change (vaporization) by calculating $\Delta S_{\text {sys }}^{\circ}$ :

$$
\begin{aligned}
\Delta S_{\text {sys }}^{\circ} & =\Sigma m S_{\text {products }}^{\circ}-\sum n S_{\text {reactants }}^{\circ}=S^{\circ} \text { of } \mathrm{H}_{2} \mathrm{O}(g ; 373 \mathrm{~K})-S^{\circ} \text { of } \mathrm{H}_{2} \mathrm{O}(l ; 373 \mathrm{~K}) \\
& =195.9 \mathrm{~J} / \mathrm{K}-86.8 \mathrm{~J} / \mathrm{K}=109.1 \mathrm{~J} / \mathrm{K}
\end{aligned}
$$

# Chemical Connections to Biology <br> Do Living Things Obey the Laws of Thermodynamics? 

0rganisms can be thought of as chemical machines that evolved by extracting energy as efficiently as possible from the environment. Such a mechanical view holds that all processes, whether they involve living or nonliving systems, are consistent with thermodynamic principles. Let's examine the first and second laws of thermodynamics to see if they apply to living systems.

Organisms certainly comply with the first law. The chemical bond energy in food is converted into the mechanical energy of sprouting, crawling, swimming, and countless other movements; the electrical energy of nerve conduction; the thermal energy of warming the body; and so forth. Many experiments have demonstrated that in all these energy conversions, the total energy is conserved. Some of the earliest studies of this question were performed by Lavoisier, who included animal respiration in his new theory of combustion (Figure B20.1). He was the first to show that "animal heat" was produced by a slow combustion process occurring continually in the body. In experiments with guinea pigs, he measured the intake of food and $\mathrm{O}_{2}$ and the output of $\mathrm{CO}_{2}$ and heat, for which he invented a calorimeter based on the melting of ice, and he established the principles and methods for measuring the basal rate of metabolism. Modern experiments using a calorimeter large enough to contain an exercising human continue to confirm the conservation of energy (Figure B20.2).

It may not seem as clear, however, that an organism, and even the whole parade of life, complies with the second law. Mature humans are far more complex than the simple egg and sperm cells from which they develop, and modern organisms are far more complex than the one-celled ancestral Apec from whe hiey evolved. Energy must be highly localized and macromolecules constrained to carry out myriad reactions that synthesize biopolymers from their monomers. Are the growth of an organism and the evolution of life exceptions to the spontaneous tendency of natural processes to disperse their energy and increase molecular free-
dom? Does biology violate the second law? Not at all, if we examine the system and its surroundings. For an organism to grow or a species to evolve, countless moles of oxygen and food molecules-carbohydrates, proteins, and fats-undergo exothermic combustion reactions to form many more moles of gaseous $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$. The formation and discharge of these waste gases, as well as the heat released, represent a tremendous net increase in the entropy of the surroundings. Thus, the localization of energy and restrictions on molecular freedom apparent in the growth and evolution of organisms occur at the expense of a far greater dispersal of energy and freedom of motion in the Earth-Sun surroundings. When system and surroundings are considered together, the entropy of the universe, as always, increases.

Figure B20.2 A whole-body calorimeter. In this room-sized apparatus, a subject exercises while respiratory gases, energy input and output, and other physiological variables are monitored.

Figure B20.1 Lavoisier studying human respiration as a form of combustion. Lavoisier (standing at right) measured substances consumed and excreted in addition to changes in heat to understand
the chemical nature of respiration. The artist (Mme. Lavoisier) shows herself taking notes (seated at right).

As we expect, the entropy of the system increases $\left(\Delta S_{\text {sys }}^{\circ}>0\right)$ as the liquid absorbs heat and changes to a gas.

For $\Delta S_{\text {surr }}$, we have

$$
\Delta S_{\text {surr }}=-\frac{\Delta H_{\mathrm{sys}}^{\circ}}{T}
$$

where $\Delta H_{\text {sys }}^{\circ}=\Delta H_{\text {vap }}^{\circ}$ at $373 \mathrm{~K}=40.7 \mathrm{~kJ} / \mathrm{mol}=40.7 \times 10^{3} \mathrm{~J} / \mathrm{mol}$. For 1 mol of water, we have

$$
\Delta S_{\text {surr }}=-\frac{\Delta H_{\text {vap }}^{\circ}}{T}=-\frac{40.7 \times 10^{3} \mathrm{~J}}{373 \mathrm{~K}}=-109 \mathrm{~J} / \mathrm{K}
$$

The surroundings lose heat, and the negative sign means that the entropy of the surroundings decreases. The two entropy changes have the same magnitude but opposite signs, so they cancel:

$$
\Delta S_{\text {univ }}=109 \mathrm{~J} / \mathrm{K}+(-109 \mathrm{~J} / \mathrm{K})=0
$$

For the reverse change (condensation), $\Delta S_{\text {univ }}$ also equals zero, but $\Delta S_{\text {sys }}^{\circ}$ and $\Delta S_{\text {surr }}$ have signs opposite those for vaporization. A similar treatment of a chemical change shows the same result: the entropy change of the forward reaction is equal in magnitude but opposite in sign to the entropy change of the reverse reaction. Thus, when a system reaches equilibrium, neither the forward nor the reverse reaction is spontaneous, and so there is no net reaction in either direction.

## Spontaneous Exothermic and Endothermic Reactions: A Summary

We can now see why exothermic and endothermic spontaneous reactions occur. No matter what its enthalpy change, a reaction occurs because the total entropy of the reacting system and its surroundings increases. The two possibilities are

1. For an exothermic reaction $\left(\Delta H_{\text {sys }}<0\right)$, heat is released by the system, whied inerease thetreedonginptionandenergy dispersed and, thus, the entropy of the surroundings ( $\Delta S_{\text {surr }}>0$ ).

- If the reacting system yields products whose entropy is greater than that of the reactants $\left(\Delta S_{\text {sys }}>0\right)$, the total entropy change $\left(\Delta S_{\text {sys }}+\Delta S_{\text {surr }}\right)$ will be positive (Figure 20.12A). For example, in the oxidation of glucose, an essential reaction for all higher organisms,

$$
\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(g) \longrightarrow 6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)+\text { heat }
$$

6 mol of gas yields 12 mol of gas and heat; thus, $\Delta S_{\text {sys }}>0, \Delta S_{\text {surr }}>0$, and $\Delta S_{\text {univ }}>0$.

- If, on the other hand, the entropy of the system decreases as the reaction occurs ( $\Delta S_{\text {sys }}<0$ ), the entropy of the surroundings must increase even more ( $\Delta S_{\text {surr }} \gg 0$ ) to make the total $\Delta S$ positive (Figure 20.12B). For example, when calcium oxide and carbon dioxide form calcium carbonate,

$$
\mathrm{CaO}(s)+\mathrm{CO}_{2}(g) \longrightarrow \mathrm{CaCO}_{3}(s)+\text { heat }
$$

the entropy of the system decreases because the amount (mol) of gas decreases. However, the heat released increases the entropy of the surroundings even more; thus, $\Delta S_{\text {sys }}<0$, but $\Delta S_{\text {surr }} \gg 0$, so $\Delta S_{\text {univ }}>0$.
2. For an endothermic reaction $\left(\Delta H_{\mathrm{sys}}>0\right)$, the heat lost by the surroundings decreases molecular freedom of motion and dispersal of energy and, thus, decreases the entropy of the surroundings $\left(\Delta S_{\text {surr }}<0\right)$. Therefore, the only way an endothermic reaction can occur spontaneously is if $\Delta S_{\text {sys }}$ is positive and large enough to outweigh the negative $\Delta S_{\text {surr }}$ (Figure 20.12C).

- In the solution process for many ionic compounds, heat is absorbed to form the solution, so the entropy of the surroundings decreases $\left(\Delta S_{\text {surr }}<0\right)$. However, when the crystalline solid becomes freely moving ions, the entropy increase is so large $\left(\Delta S_{\text {sys }} \gg 0\right)$ that it outweighs the negative $\Delta S_{\text {surr }}$. Thus, $\Delta S_{\text {univ }}$ is positive.

Figure 20.12 Components of $\Delta S_{\text {univ }}$ for spontaneous reactions. For a reaction to occur spontaneously, $\Delta S_{\text {univ }}$ must be positive. A, An exothermic reaction in which $\Delta S_{\text {sys }}$ increases; the size of $\Delta S_{\text {surr }}$ is not

- Spontaneous endothermic reactions have similar features. For example, consider the reaction between barium hydroxide octahydrate and ammonium nitrate (see Figure 20.1, p. 883),

$$
\begin{array}{r}
\text { heat }+\mathrm{Ba}(\mathrm{OH})_{2} \cdot 8 \mathrm{H}_{2} \mathrm{O}(s)+2 \mathrm{NH}_{4} \mathrm{NO}_{3}(s) \longrightarrow \\
\mathrm{Ba}^{2+}(a q)+2 \mathrm{NO}_{3}^{-}(a q)+2 \mathrm{NH}_{3}(a q)+10 \mathrm{H}_{2} \mathrm{O}(l)
\end{array}
$$

In this endothermic reaction, 3 mol of crystalline solids absorbs heat from the surroundings ( $\Delta S_{\text {surr }}<0$ ) and yields 15 mol of dissolved ions and molecules, which have much more freedom of motion and, therefore, much greater entropy ( $\Delta S_{\text {sys }} \gg 0$ ).

## Section Summary

The standard entropy of reaction, $\Delta S_{\mathrm{rxn}}^{\circ}$, is calculated from $S^{\circ}$ values. - When the amount (mol) of gas $\left(\Delta n_{\text {gas }}\right)$ increases in a reaction, usually $\Delta S_{\text {rxn }}^{\circ}>0$. - The value of $\Delta S_{\text {surr }}$ is related directly to $\Delta H_{\text {sys }}^{\circ}$ and inversely to the $T$ at which the change occurs. - In a spontaneous change, the entropy of the system can decrease only if the entropy of the surroundings increases even more. - For a system at equilibrium, $\Delta S_{\text {univ }}=0$.

### 20.3 ENTROPY, FREE ENERGY, AND WORK

By making two separate measurements, $\Delta S_{\text {sys }}$ and $\Delta S_{\text {surr }}$, we can predict whether a reaction will be spontaneous at a particular temperature. It would be useful, however, to have one criterion for spontaneity that we can find by examining the system only. The Gibbs free energy, or simply free energy $(\boldsymbol{G})$, is a function that combines the system's enthalpy and entropy:

$$
G=H-T S
$$

Named for Josiah Willard Gibbs, the physicist who proposed it and laid much of the foundation for chemical thermodynamics, this function provides the criterion for spontaneity we've been seeking.

## Free Energy Change and Reaction Spontaneity

The free energy change $(\Delta G)$ is a measure of the spontaneity of a process and of the useful energy available from it. Let's see how the free energy change is derived from the second law of thermodynamics. Recall that by definition, the entropy change of the universe is the sum of the entropy changes of the system and the surroundings:

$$
\Delta S_{\text {univ }}=\Delta S_{\text {sys }}+\Delta S_{\text {surr }}
$$

The Greatness and Obscurity of J. Willard Gibbs Even today, one of the greatest minds in science is barely known outside chemistry and physics. In 1878, Josiah Willard Gibbs (1839-1903), a professor of mathematical physics at Yale, completed a 323-page paper that virtually established the science of chemical thermodynamics and major principles governing chemical equilibria, phasechange equilibria, and the energy changes in electrochemical cells. The European scientists James Clerk Maxwell, Wilhelm Ostwald, and Henri Le Châtelier realized the significance of Gibbs's achievements long before most of his American colleagues did. In fact, he was elected to the Hall of Fame of Distinguished Americans as late as 1950 because, embarrassingly, he had not received enough votes until then!

At constant pressure,

$$
\Delta S_{\text {surr }}=-\frac{\Delta H_{\mathrm{sys}}}{T}
$$

Substituting for $\Delta S_{\text {surr }}$ gives a relationship that lets us focus solely on the system:

$$
\Delta S_{\text {univ }}=\Delta S_{\text {sys }}-\frac{\Delta H_{\text {sys }}}{T}
$$

Multiplying both sides by $-T$ gives

$$
-T \Delta S_{\text {univ }}=\Delta H_{\text {sys }}-T \Delta S_{\text {sys }}
$$

Now we can introduce the new free energy quantity to replace the enthalpy and entropy terms. From $G=H-T S$, the Gibbs equation shows us the change in the free energy of the system $\left(\Delta G_{\text {sys }}\right)$ at constant temperature and pressure:

$$
\begin{equation*}
\Delta G_{\mathrm{sys}}=\Delta H_{\mathrm{sys}}-T \Delta S_{\mathrm{sys}} \tag{20.6}
\end{equation*}
$$

Combining this equation with the previous one shows that

$$
-T \Delta S_{\text {univ }}=\Delta H_{\text {sys }}-T \Delta S_{\text {sys }}=\Delta G_{\text {sys }}
$$

The sign of $\Delta G$ tells if a reaction is spontaneous. The second law dictates

- $\Delta S_{\text {univ }}>0$ for a spontaneous process
- $\Delta S_{\text {univ }}<0$ for a nonspontaneous process
- $\Delta S_{\text {univ }}=0$ for a process at equilibrium

Of course, absolute temperature is always positive, so

$$
T \Delta S_{\text {univ }}>0 \quad \text { or } \quad-T \Delta S_{\text {univ }}<0 \text { for a spontaneous process }
$$

Because $\Delta G=-T \Delta S_{\text {univ }}$, we know that

- ABaç for asporfaneousproess ceI
- $\Delta G>0$ for a nonspontaneous process
- $\Delta G=0$ for a process at equilibrium

An important point to keep in mind is that if a process is nonspontaneous in one direction $(\Delta G>0)$, it is spontaneous in the opposite direction $(\Delta G<0)$. By using $\Delta G$, we have not incorporated any new ideas, but we can predict reaction spontaneity from one variable ( $\Delta G_{\text {sys }}$ ) rather than two ( $\Delta S_{\text {sys }}$ and $\Delta S_{\text {surr }}$ ).

As we noted at the beginning of the chapter, the degree of spontaneity of a reaction-that is, the sign and magnitude of $\Delta G$-tells us nothing about the rate of the reaction. Remember that some spontaneous reactions are extremely slow. For example, the reaction between $\mathrm{H}_{2}(g)$ and $\mathrm{O}_{2}(g)$ at room temperature is highly spontaneous- $\Delta G$ has a large negative value-but in the absence of a catalyst or a flame, the reaction doesn't occur to a measurable extent because its rate is so low.

## Calculating Standard Free Energy Changes

Because free energy $(G)$ combines three state functions, $H, S$, and $T$, it is also a state function. As with enthalpy, we focus on the free energy change $(\Delta G)$.
The Standard Free Energy Change As we did previously with the other thermodynamic variables, to compare the free energy changes of different reactions we calculate the standard free energy change $\left(\Delta G^{\circ}\right)$, which occurs when all components of the system are in their standard states. Adapting the Gibbs equation (20.6), we have

$$
\begin{equation*}
\Delta G_{\mathrm{sys}}^{\circ}=\Delta H_{\mathrm{sys}}^{\circ}-T \Delta S_{\mathrm{sys}}^{\circ} \tag{20.7}
\end{equation*}
$$

This important relationship is used frequently to find any one of these three central thermodynamic variables, given the other two, as in Sample Problem 20.4.

## SAMPLE PROBLEM 20.4 Calculating $\Delta G_{r \times n}^{\circ}$ from Enthalpy and Entropy Values

PROBLEM Potassium chlorate, a common oxidizing agent in fireworks (see photo) and matchheads, undergoes a solid-state disproportionation reaction when heated:

$$
4 \stackrel{+5}{\mathrm{KlO}}_{3}(s) \xrightarrow{\Delta} 3{\stackrel{+7}{\mathrm{KClO}_{4}}(s)+\stackrel{-1}{\mathrm{KCl}}(s) .}^{(s)}
$$

Use $\Delta H_{\mathrm{f}}^{\circ}$ and $S^{\circ}$ values to calculate $\Delta G_{\text {sys }}^{\circ}\left(\Delta G_{\mathrm{rxn}}^{\circ}\right)$ at $25^{\circ} \mathrm{C}$ for this reaction.
PLAN To solve for $\Delta G^{\circ}$, we need values from Appendix B. We use $\Delta H_{\mathrm{f}}^{\circ}$ values to calculate $\Delta H_{\mathrm{rxn}}^{\circ}\left(\Delta H_{\mathrm{sys}}^{\circ}\right)$, use $S^{\circ}$ values to calculate $\Delta S_{\mathrm{rxn}}^{\circ}\left(\Delta S_{\mathrm{sys}}^{\circ}\right)$, and then apply Equation 20.7. SOLUTION Calculating $\Delta H_{\text {sys }}^{\circ}$ from $\Delta H_{\mathrm{f}}^{\circ}$ values (with Equation 6.8):

$$
\begin{aligned}
\Delta H_{\mathrm{sys}}^{\circ}= & \Delta H_{\mathrm{rxn}}^{\circ}=\sum m \Delta H_{\mathrm{f} \text { (products) }}^{\circ}-\sum n \Delta H_{\mathrm{f}}^{\circ} \text { (reactants) } \\
= & {\left[\left(3 \mathrm{~mol} \mathrm{KCO}_{4}\right)\left(\Delta H_{\mathrm{f}}^{\circ} \text { of } \mathrm{KClO}_{4}\right)+(1 \mathrm{~mol} \mathrm{KCl})\left(\Delta H_{\mathrm{f}}^{\circ} \text { of } \mathrm{KCl}\right)\right] } \\
& -\left[\left(4 \mathrm{~mol} \mathrm{KClO}_{3}\right)\left(\Delta H_{\mathrm{f}}^{\circ} \text { of } \mathrm{KClO}_{3}\right)\right] \\
= & {[(3 \mathrm{~mol})(-432.8 \mathrm{~kJ} / \mathrm{mol})+(1 \mathrm{~mol})(-436.7 \mathrm{~kJ} / \mathrm{mol})] } \\
& -[(4 \mathrm{~mol})(-397.7 \mathrm{~kJ} / \mathrm{mol})] \\
= & -144 \mathrm{~kJ}
\end{aligned}
$$

Calculating $\Delta S_{\text {sys }}^{\circ}$ from $S^{\circ}$ values (with Equation 20.4):

$$
\begin{aligned}
& \Delta S_{\mathrm{sys}}^{\circ}=\Delta S_{\mathrm{rxn}}^{\circ}=\Sigma m S_{\text {products }}^{\circ}-\Sigma n S_{\text {reactants }}^{\circ} \\
& =\left[\left(3 \mathrm{~mol} \mathrm{KClO}_{4}\right)\left(S^{\circ} \text { of } \mathrm{KClO}_{4}\right)\right. \\
& \left.+(1 \mathrm{~mol} \mathrm{KCl})\left(S^{\circ} \text { of } \mathrm{KCl}\right)\right]-\left[(4 \mathrm{~mol} \mathrm{KClO} 3)\left(S^{\circ} \text { of } \mathrm{KClO}_{3}\right)\right] \\
& =[(3 \mathrm{~mol})(151.0 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})+(1 \mathrm{~mol})(82.6 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})] \\
& -[(4 \mathrm{~mol})(143.1 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})] \\
& =-36.8 \mathrm{~J} / \mathrm{K}
\end{aligned}
$$

Calculating $\Delta G_{\text {sys }}^{\circ}$ at 298 K :

$$
\Delta G_{\mathrm{sys}}^{\circ}=\Delta H_{\mathrm{sys}}^{\circ}-T \Delta S_{\mathrm{sys}}^{\circ}=-144 \mathrm{~kJ}-\left[(298 \mathrm{~K})(-36.8 \mathrm{~J} / \mathrm{K})\left(\frac{1 \mathrm{~kJ}}{1000 \mathrm{~J}}\right)\right]=-133 \mathrm{~kJ}
$$

CHECK Rounding to check the math:

$$
\begin{aligned}
\Delta H^{\circ} \approx[3(-433 \mathrm{~kJ})+(-440 \mathrm{~kJ})]-[4(-400 \mathrm{~kJ})]=-1740 \mathrm{~kJ}+1600 \mathrm{~kJ}=-140 \mathrm{~kJ} \\
\Delta S^{\circ} \approx[3(150 \mathrm{~J} / \mathrm{K})+85 \mathrm{~J} / \mathrm{K}]-[4(145 \mathrm{~J} / \mathrm{K})]=535 \mathrm{~J} / \mathrm{K}-580 \mathrm{~J} / \mathrm{K}=-45 \mathrm{~J} / \mathrm{K} \\
\Delta G^{\circ} \approx-140 \mathrm{~kJ}-300 \mathrm{~K}(-0.04 \mathrm{~kJ} / \mathrm{K})=-140 \mathrm{~kJ}+12 \mathrm{~kJ}=-128 \mathrm{~kJ}
\end{aligned}
$$

All values are close to the calculated ones. Another way to calculate $\Delta G^{\circ}$ for this reaction is presented in Sample Problem 20.5.
COMMENT 1. For a spontaneous reaction under any conditions, the free energy change, $\Delta G$, is negative. Under standard-state conditions, a spontaneous reaction has a negative standard free energy change; that is, $\Delta G^{\circ}<0$.
2. This reaction is spontaneous, but the rate is very low in the solid. When $\mathrm{KClO}_{3}$ is heated slightly above its melting point, the ions are free to move and the reaction occurs readily. FOLLOW-UP PROBLEM 20.4 Determine the standard free energy change at 298 K for the reaction $2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)$.

The Standard Free Energy of Formation Another way to calculate $\Delta G_{\mathrm{rxn}}^{\circ}$ is with values for the standard free energy of formation ( $\Delta \boldsymbol{G}_{\mathbf{f}}^{\circ}$ ) of the components; $\Delta G_{f}^{\circ}$ is the free energy change that occurs when 1 mol of compound is made from its elements, with all components in their standard states. Because free energy is a state function, we can combine $\Delta G_{\mathrm{f}}^{\circ}$ values of reactants and products to calculate $\Delta G_{\mathrm{rxn}}^{\circ}$ no matter how the reaction takes place:

$$
\begin{equation*}
\Delta G_{\mathrm{rxn}}^{\circ}=\Sigma m \Delta G_{\mathrm{f}(\mathrm{products})}^{\circ}-\Sigma n \Delta G_{\mathrm{f}(\text { reactants })}^{\circ} \tag{20.8}
\end{equation*}
$$

$\Delta G_{\mathrm{f}}^{\circ}$ values have properties similar to $\Delta H_{\mathrm{f}}^{\circ}$ values:

- $\Delta G_{\mathrm{f}}^{\circ}$ of an element in its standard state is zero.
- An equation coefficient ( $m$ or $n$ above) multiplies $\Delta G_{\mathrm{f}}^{\circ}$ by that number.
- Reversing a reaction changes the sign of $\Delta G_{f}^{\circ}$.

Many $\Delta G_{\mathrm{f}}^{\circ}$ values appear along with those for $\Delta H_{\mathrm{f}}^{\circ}$ and $S^{\circ}$ in Appendix B.

Potassium chlorate is the oxidizing agent in fireworks.

## SAMPLE PROBLEM 20.5 Calculating $\Delta G_{r \times n}^{\circ}$ from $\Delta G_{f}^{\circ}$ Values

PROBLEM Use $\Delta G_{\mathrm{f}}^{\circ}$ values to calculate $\Delta G_{\mathrm{rxn}}^{\circ}$ for the reaction in Sample Problem 20.4:

$$
4 \mathrm{KClO}_{3}(s) \longrightarrow 3 \mathrm{KClO}_{4}(s)+\mathrm{KCl}(s)
$$

PLAN We apply Equation 20.8 to calculate $\Delta G_{\mathrm{rxn}}^{\circ}$. SOLUTION

$$
\begin{aligned}
\Delta G_{\mathrm{rxn}}^{\circ}= & \sum m \Delta G_{\mathrm{f}(\text { products })}^{\circ}-\sum n \Delta G_{\mathrm{f}(\text { reactants })}^{\circ} \\
= & {\left[\left(3 \mathrm{~mol} \mathrm{KClO}_{4}\right)\left(\Delta G_{\mathrm{f}}^{\circ} \text { of } \mathrm{KClO}_{4}\right)+(1 \mathrm{~mol} \mathrm{KCl})\left(\Delta G_{\mathrm{f}}^{\circ} \text { of } \mathrm{KCl}\right)\right] } \\
& -\left[\left(4 \mathrm{~mol} \mathrm{KClO}_{3}\right)\left(\Delta G_{\mathrm{f}}^{\circ} \text { of } \mathrm{KClO}_{3}\right)\right] \\
= & {[(3 \mathrm{~mol})(-303.2 \mathrm{~kJ} / \mathrm{mol})+(1 \mathrm{~mol})(-409.2 \mathrm{~kJ} / \mathrm{mol})] } \\
& -[(4 \mathrm{~mol})(-296.3 \mathrm{~kJ} / \mathrm{mol})] \\
= & -134 \mathrm{~kJ}
\end{aligned}
$$

CHECK Rounding to check the math:
$\Delta G_{\mathrm{rxn}}^{\circ} \approx[3(-300 \mathrm{~kJ})+1(-400 \mathrm{~kJ})]-4(-300 \mathrm{~kJ})$

$$
=-1300 \mathrm{~kJ}+1200 \mathrm{~kJ}=-100 \mathrm{~kJ}
$$

COMMENT The slight discrepancy between this answer and that obtained in Sample Problem 20.4 is within experimental error. As you can see, when $\Delta G_{\mathrm{f}}^{\circ}$ values are available for a reaction taking place at $25^{\circ} \mathrm{C}$, this method is simpler than that in Sample Problem 20.4.
FOLLOW-UP PROBLEM 20.5 Use $\Delta G_{f}^{\circ}$ values to calculate the free energy change at $25^{\circ} \mathrm{C}$ for each of the following reactions:
(a) $2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)$ (from Follow-up Problem 20.4)
(b) 2 C (graphite) $+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}(g)$

## $\Delta G$ and the Work a System Can Do

 the steam engine, and one of the most practical relationships in the field is that between the free energy change and the work a system can do:

- For a spontaneous process $(\Delta G<0)$ at constant $T$ and $P, \Delta G$ is the maximum useful work obtainable from the system as the process takes place:

$$
\begin{equation*}
\Delta G=w_{\max } \tag{20.9}
\end{equation*}
$$

- For a nonspontaneous process $(\Delta G>0)$ at constant $T$ and $P, \Delta G$ is the minimum work that must be done to the system to make the process take place.

The phrase "maximum useful work obtainable" requires some explanation. First, what do we mean by the "maximum work obtainable," and what determines this limit? The free energy change is the maximum work the system can possibly do. But the work the system actually does depends on how that change in free energy is released. Let's first consider a nonchemical process. Suppose a gas is confined within a cylinder, at $V_{\text {initial }}$, by a piston attached to a $1-\mathrm{kg}$ brass weight (Figure 20.13A). As the gas expands and lifts the weight, its pressure becomes balanced by the weight at some final volume, $V_{\text {final }}$ (Figure 20.13B). The gas lifted the weight in one step, thus doing a certain quantity of work. As the number of steps increases, the quantity of work done by the gas increases. Thus, the gas can do more work in two steps, by lifting a $2-\mathrm{kg}$ weight to one-half $V_{\text {final }}$ and then lifting the $1-\mathrm{kg}$ weight the rest of the way to $V_{\text {final }}$. Lifting the weight in three steps would do even more work. The gas would get closer to performing the maximum work if the brass weight were replaced by a container of sand so that the weight could be lifted grain by grain, that is, almost infinitesimally. (We described a similar method for finding the entropy change on p. 887.) In this way, the gas would lift the container in a very high number of steps.

However, only in a hypothetical process in which the work is done in an infinite number of steps, and an infinitesimal increase in the weight reverses the expansion, can the maximum work be done: the maximum work is done by a spontaneous process only if the work is carried out reversibly. Of course, in any real process, work is performed irreversibly, that is, in a finite number of steps, so we can never obtain the maximum work. The free energy not used for work is lost to the surroundings as heat. This "unharnessed" energy is a consequence of any real process.

Next, what do we mean by "useful work"? As the gas expands and raises the weights, some of the work just pushes back the atmosphere. That work increases the atmosphere's energy, but it doesn't do anything useful, such as turn a turbine, run a car, etc. By the same token, if we wanted to compress the gas, the atmosphere would do part of the work by pushing on the piston, but that part of the work doesn't come from our muscles or from gasoline or from the power company. The $\Delta G$ function ignores the work done to or by the atmosphere and tells us about the work we can use or have to do ourselves.

Let's consider two examples of systems that use a chemical reaction to do useful work-a car engine and a battery. When gasoline (represented here by octane) is burned in a car engine,

$$
\mathrm{C}_{8} \mathrm{H}_{18}(l)+\frac{25}{2} \mathrm{O}_{2}(g) \longrightarrow 8 \mathrm{CO}_{2}(g)+9 \mathrm{H}_{2} \mathrm{O}(g)
$$

a large amount of energy is given off as heat ( $\Delta H_{\text {sys }}<0$ ), and because the number of moles of gas increases, the entropy of the system increases $\left(\Delta S_{\mathrm{sys}}>0\right)$. Therefore, the reaction is spontaneous ( $\Delta G_{\text {sys }}<0$ ). The free energy available does work turning wheels, moving belts, playing a CD, and so on. However, only if it is released reversibly, that is, in a series of infinitesimal steps, do we obtain the maximum work available from this reaction. In reality, the process is carried out irreversibly and much of the total frepeqeegyustperps thereqine thecpassenger compartment, and the outside air, which increases the freedom of motion of the particles in the universe, in accord with the second law.

As you'll see in Chapter 21, a battery is essentially a packaged spontaneous redox reaction that releases free energy to the surroundings (flashlight, radio, motor, etc.). If we connect the battery terminals to each other through a short piece of wire, the free energy change is released all at once but does no workit just heats the wire and battery. If we connect the terminals to a motor, the free energy is released more slowly, and a sizeable portion of it runs the motor, but some is still converted to heat in the battery and the motor. If we discharge the battery still more slowly, more of the free energy change does work and less is converted to heat, but only when the battery discharges infinitely slowly can we obtain the maximum quantity of work.

The compromise that all engineers and machine designers must face is that, in the real world, some free energy is always changed to heat and is, thus, unharnessed: no real process uses all the available free energy to do work.

Let's summarize the relationship between the free energy change of a reaction and the work it can actually do:

- A spontaneous reaction $\left(\Delta G_{\text {sys }}<0\right)$ will occur and can do work on the surroundings ( $-w$ ). In any real machine, however, the actual work done by the reaction is always less than the maximum possible because some of the $\Delta G$ released is lost as heat.
- A nonspontaneous reaction $\left(\Delta G_{\text {sys }}>0\right)$ will not occur unless the surroundings do work on it $(+w)$. In any real machine, however, the actual work done on the reaction is always more than the minimum because some of the $\Delta G$ added is lost as heat.
- A reaction at equilibrium $\left(\Delta G_{\text {sys }}=0\right)$ can no longer do any work.

The Wide Range of Energy Efficiency
One definition for the efficiency of a device is the percentage of the energy input that results in work output. The range of efficiencies is enormous for the common "energy-conversion systems" of society. For instance, a common incandescent lightbulb converts only $5 \%$ of incoming electrical energy to light, the rest is given off as heat. At the other extreme, a large electrical generator converts $99 \%$ of the incoming mechanical energy to electricity. Although improvements are continually being made, here are some efficiency values for other devices: home oil furnace, $65 \%$; hand tool motor, $63 \%$; liquid fuel rocket, $50 \%$; car engine, $<30 \%$; fluorescent lamp, $20 \%$; solar cell, $\sim 15 \%$.

## The Effect of Temperature on Reaction Spontaneity

In most cases, the enthalpy contribution $(\Delta H)$ to the free energy change $(\Delta G)$ is much larger than the entropy contribution $(T \Delta S)$. For this reason, most exothermic reactions are spontaneous: the negative $\Delta H$ helps make $\Delta G$ negative. However, the temperature of a reaction influences the magnitude of the TDS term, so, for many reactions, the overall spontaneity depends on the temperature.

By scrutinizing the signs of $\Delta H$ and $\Delta S$, we can predict the effect of temperature on the sign of $\Delta G$. The values for the thermodynamic variables in this discussion are based on standard state values from Appendix B, but we show them without the degree sign to emphasize that the relationships among $\Delta G, \Delta H$, and $\Delta S$ are valid at any conditions. Also, we assume that $\Delta H$ and $\Delta S$ change little with temperature, which is true as long as no phase changes occur.

Let's examine the four combinations of positive and negative $\Delta H$ and $\Delta S$ two combinations that are independent of temperature and two that are dependent on temperature:

- Temperature-independent cases. When $\Delta H$ and $\Delta S$ have opposite signs, the reaction occurs spontaneously either at all temperatures or at none.

1. Reaction is spontaneous at all temperatures: $\Delta H<0, \Delta S>0$. Both contributions favor the spontaneity of the reaction. $\Delta H$ is negative and $\Delta S$ is positive, so $-T \Delta S$ is negative; thus, $\Delta G$ is always negative. Most combustion reactions are in this category. The decomposition of hydrogen peroxide, a common disinfectant, is also spontaneous at all temperatures:

$$
\begin{gathered}
2 \mathrm{H}_{2} \mathrm{O}_{2}(l) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{O}_{2}(g) \\
\Delta H=-196 \mathrm{~kJ} \quad \text { and } \quad \Delta S=125 \mathrm{~J} / \mathrm{K}
\end{gathered}
$$

$A^{2}$ Reactign ispuopspontaneous at all temperatures: $\Delta H>0, \Delta S<0$. Both contributions oppose the spontanety of the reaction. $\Delta H$ is positive and $\Delta S$ is negative, so $-T \Delta S$ is positive; thus, $\Delta G$ is always positive. The formation of ozone from oxygen is not spontaneous at any temperature:

$$
\begin{gathered}
3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{O}_{3}(\mathrm{~g}) \\
\Delta H=286 \mathrm{~kJ} \quad \text { and } \quad \Delta S=-137 \mathrm{~J} / \mathrm{K}
\end{gathered}
$$

- Temperature-dependent cases. When $\Delta H$ and $\Delta S$ have the same sign, the relative magnitudes of the $-T \Delta S$ and $\Delta H$ terms determine the sign of $\Delta G$. In these cases, the magnitude of $T$ is crucial to reaction spontaneity.

3. Reaction is spontaneous at higher temperatures: $\Delta H>0$ and $\Delta S>0$. Here, $\Delta S$ favors spontaneity ( $-T \Delta S<0$ ), but $\Delta H$ does not. For example,

$$
\begin{gathered}
2 \mathrm{~N}_{2} \mathrm{O}(g)+\mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{NO}(g) \\
\Delta H=197.1 \mathrm{~kJ} \quad \text { and } \quad \Delta S=198.2 \mathrm{~J} / \mathrm{K}
\end{gathered}
$$

With a positive $\Delta H$, the reaction will occur spontaneously only when $-T \Delta S$ is large enough to make $\Delta G$ negative, which will happen at higher temperatures. The oxidation of $\mathrm{N}_{2} \mathrm{O}$ occurs spontaneously at $T>994 \mathrm{~K}$.
4. Reaction is spontaneous at lower temperatures: $\Delta H<0$ and $\Delta S<0$. Now, $\Delta H$ favors spontaneity, but $\Delta S$ does not ( $-T \Delta S>0$ ). For example,

$$
\begin{gathered}
4 \mathrm{Fe}(s)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Fe}_{2} \mathrm{O}_{3}(s) \\
\Delta H=-1651 \mathrm{~kJ} \quad \text { and } \quad \Delta S=-549.4 \mathrm{~J} / \mathrm{K}
\end{gathered}
$$

With a negative $\Delta H$, the reaction will occur spontaneously only if the $-T \Delta S$ term is smaller than the $\Delta H$ term, and this happens at lower temperatures. The production of iron(III) oxide occurs spontaneously at any $T<3005 \mathrm{~K}$.

Table 20.1 summarizes these four possible combinations of $\Delta H$ and $\Delta S$, and Sample Problem 20.6 applies them to physical and chemical changes.

Table 20.1 Reaction Spontaneity and the Signs of $\Delta H, \Delta S$, and $\Delta G$

| $\Delta H$ | $\Delta S$ | -TAS | $\Delta G$ | Description |
| :---: | :---: | :---: | :---: | :---: |
| - | $+$ | - | - | Spontaneous at all $T$ |
| $+$ | - | + | + | Nonspontaneous at all $T$ |
| + | + | - | + or - | Spontaneous at higher $T$; nonspontaneous at lower $T$ |
| - | - | + | + or - | Spontaneous at lower $T$; nonspontaneous at higher $T$ |

SAMPLE PROBLEM 20.6 Using Molecular Scenes to Determine the Signs of $\Delta H, \Delta S$, and $\Delta G$
PROBLEM The following scenes represent a familiar phase change for water (blue spheres):

(a) What are the signs of $\Delta H$ and $\Delta S$ for this process? Explain.
(b) Is the process spontaneous at all $T$, no $T$, low $T$, or high $T$ ? Explain.

PLAN The scenes depict water vapor on the left and liquid water on the right. (a) From the scenes, we determine any change in amount of gas, which indicates the sign of $\Delta S$, and any change in the freedom of motion of the particles, which indicates whether heat is absorbed or released, and thus the sign of $\Delta H$. (b) The question refers to the sign of $\Delta G$ $(+$ or -$)$ at the different temperature possibilities, so we apply Equation 20.6 and refer to the previous text discussion and Table 20.1.
SOLUTION (a) The scene represents the condensation of water vapor, so the amount of gas decreases dramatically, and the separated molecules give up energy as they come closer together. Therefore, $\Delta S<0$ and $\Delta H<0$. (b) According to Equation 20.6, with $\Delta S$ negative, the $-T \Delta S$ term is positive. In order for $\Delta G<0$, the magnitude of $T$ must be small. Therefore, the process is spontaneous at low $T$.
CHECK The answer in part (b) seems reasonable based on our analysis in part (a). The answer makes sense because we know from everyday experience that water condenses spontaneously, and it does so at low temperatures.
FOLLOW-UP PROBLEM 20.6 The following molecular scenes represent the gas-phase decomposition of $\mathrm{X}_{2} \mathrm{Y}_{2}$ to $\mathrm{X}_{2}$ (red) and $\mathrm{Y}_{2}$ (blue):

(a) What is the sign of $\Delta S$ for the reaction?
(b) If the reaction is spontaneous only above $325^{\circ} \mathrm{C}$, what is the sign of $\Delta H$ ? Explain.

As you saw in Sample Problem 20.4, one way to calculate $\Delta G$ is from enthalpy and entropy changes. Because $\Delta H$ and $\Delta S$ usually change little with temperature if no phase changes occur, we use their values at 298 K in Sample Problem 20.7 to examine the effect of $T$ on $\Delta G$ and, thus, on reaction spontaneity.

## SAMPLE PROBLEM 20.7 Determining the Effect of Temperature on $\Delta G$

PROBLEM A key step in the production of sulfuric acid is the oxidation of $\mathrm{SO}_{2}(\mathrm{~g})$ to $\mathrm{SO}_{3}(\mathrm{~g})$ :

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{SO}_{3}(g)
$$

At $298 \mathrm{~K}, \Delta G=-141.6 \mathrm{~kJ} ; \Delta H=-198.4 \mathrm{~kJ}$; and $\Delta S=-187.9 \mathrm{~J} / \mathrm{K}$.
(a) Use the data to decide if this reaction is spontaneous at $25^{\circ} \mathrm{C}$, and predict how $\Delta G$ will change with increasing $T$.
(b) Assuming that $\Delta H$ and $\Delta S$ are constant with $T$, is the reaction spontaneous at $900 .{ }^{\circ} \mathrm{C}$ ? PLAN (a) We note the sign of $\Delta G$ to see if the reaction is spontaneous and the signs of $\Delta H$ and $\Delta S$ to see the effect of $T$. (b) We use Equation 20.7 to calculate $\Delta G$ from the given $\Delta H$ and $\Delta S$ at the higher $T$ (in K).
SOLUTION (a) $\Delta G<0$, so the reaction is spontaneous at $298 \mathrm{~K}: \mathrm{SO}_{2}$ and $\mathrm{O}_{2}$ will form $\mathrm{SO}_{3}$ spontaneously. With $\Delta S<0$, the term $-T \Delta S>0$, and this term will become more positive at higher $T$. Therefore,
$\Delta G$ will become less negative, and the reaction less spontaneous, with increasing $T$.
(b) Calculating $\Delta G$ at $900 .{ }^{\circ} \mathrm{C}(T=273+900 .=1173 \mathrm{~K})$ :

$$
\Delta G=\Delta H-T \Delta S=-198.4 \mathrm{~kJ}-[(1173 \mathrm{~K})(-187.9 \mathrm{~J} / \mathrm{K})(1 \mathrm{~kJ} / 1000 \mathrm{~J})]=22.0 \mathrm{~kJ}
$$

$\Delta G>0$, so the reaction is nonspontaneous at the higher $T$.
CHECK The answer in part (b) seems reasonable based on our prediction in part (a). The arithmetic seems correct, given considerable rounding:

$$
\Delta G \approx-200 \mathrm{~kJ}-[(1200 \mathrm{~K})(-200 \mathrm{~J} / \mathrm{K}) / 1000 \mathrm{~J}]=+40 \mathrm{~kJ}
$$

FOLLOW-UP PROBLEM 20.7 A reaction is nonspontaneous at room temperature but is spontaneous at $-40^{\circ} \mathrm{C}$. What can you say about the signs and relative magnitudes of $\Delta H, \Delta S$, and $-T \Delta S$ ?

The Temperatureat Whictereeation Becomes Spontaneous As you have just seen, when the signs of $\Delta H$ and $\Delta S$ are the same, some reactions that are nonspontaneous at one temperature become spontaneous at another, and vice versa. It would certainly be useful to know the temperature at which a reaction becomes spontaneous. This is the temperature at which a positive $\Delta G$ switches to a negative $\Delta G$ because of the changing magnitude of the $-T \Delta S$ term. We find this "crossover" temperature by setting $\Delta G$ equal to zero and solving for $T$ :

$$
\Delta G=\Delta H-T \Delta S=0
$$

Therefore,

$$
\begin{equation*}
\Delta H=T \Delta S \quad \text { and } \quad T=\frac{\Delta H}{\Delta S} \tag{20.10}
\end{equation*}
$$

Consider the reaction of copper(I) oxide with carbon, which does not occur at lower temperatures but is used at higher temperatures in a step during the extraction of copper metal from chalcocite:

$$
\mathrm{Cu}_{2} \mathrm{O}(s)+\mathrm{C}(s) \longrightarrow 2 \mathrm{Cu}(s)+\mathrm{CO}(g)
$$

We predict this reaction has a positive entropy change because the number of moles of gas increases; in fact, $\Delta S=165 \mathrm{~J} / \mathrm{K}$. Furthermore, because the reaction is nonspontaneous at lower temperatures, it must have a positive $\Delta H(58.1 \mathrm{~kJ})$. As the $-T \Delta S$ term becomes more negative at higher temperatures, it will eventually outweigh the positive $\Delta H$ term, and the reaction will occur spontaneously.

Let's calculate $\Delta G$ for this reaction at $25^{\circ} \mathrm{C}$ and then find the temperature above which the reaction is spontaneous. At $25^{\circ} \mathrm{C}(298 \mathrm{~K})$,

$$
\Delta G=\Delta H-T \Delta S=58.1 \mathrm{~kJ}-\left(298 \mathrm{~K} \times 165 \mathrm{~J} / \mathrm{K} \times \frac{1 \mathrm{~kJ}}{1000 \mathrm{~J}}\right)=8.9 \mathrm{~kJ}
$$

Because $\Delta G$ is positive, the reaction will not proceed on its own at $25^{\circ} \mathrm{C}$. At the crossover temperature, $\Delta G=0$, so

$$
T=\frac{\Delta H}{\Delta S}=\frac{58.1 \mathrm{~kJ} \times \frac{1000 \mathrm{~J}}{1 \mathrm{~kJ}}}{165 \mathrm{~J} / \mathrm{K}}=352 \mathrm{~K}
$$

At any temperature above $352 \mathrm{~K}\left(79^{\circ} \mathrm{C}\right)$, a moderate one for recovering a metal from its ore, the reaction occurs spontaneously. Figure 20.14 depicts this result. The line for $T \Delta S$ rises steadily (and thus the $-T \Delta S$ term becomes more negative) with rising temperature. This line crosses the relatively constant $\Delta H$ line at 352 K . At any higher temperature, the $-T \Delta S$ term is greater than the $\Delta H$ term, so $\Delta G$ is negative.

## Coupling of Reactions to Drive a Nonspontaneous Change

When considering the spontaneity of a complex, multistep reaction, we often find that a nonspontaneous step is driven by a spontaneous step in a coupling of reactions. One step supplies enough free energy for the other to occur, just as the combustion of gasoline supplies enough free energy to move a car.

Look again at the reduction of copper(I) oxide by carbon. Previously, we found that the overall reaction becomes spontaneous at any temperature above 352 K . Dividing the reaction into two steps, however, we find that even at a higher temperature, such as 375 K , copper(I) oxide does not spontaneously decompose to its elements:

$$
\mathrm{Cu}_{2} \mathrm{O}(s) \longrightarrow 2 \mathrm{Cu}(s)+\frac{1}{2} \mathrm{O}_{2}(g) \quad \Delta G_{375}=140.0 \mathrm{~kJ}
$$

However, the oxidation of carbon to CO at 375 K is quite spontaneous:

Coupling these reactions means having the carbon in contact with the $\mathrm{Cu}_{2} \mathrm{O}$, which allows the reaction with the larger negative $\Delta G$ to "drive" the one with the smaller positive $\Delta G$. Adding the reactions together and canceling the common substance $\left(\frac{1}{2} \mathrm{O}_{2}\right)$ gives an overall reaction with a negative $\Delta G$ :

$$
\mathrm{Cu}_{2} \mathrm{O}(s)+\mathrm{C}(s) \longrightarrow 2 \mathrm{Cu}(s)+\mathrm{CO}(g) \quad \Delta G_{375}=-3.8 \mathrm{~kJ}
$$

Many biochemical reactions are also nonspontaneous. Key steps in the synthesis of proteins and nucleic acids, the formation of fatty acids, the maintenance of ion balance, and the breakdown of nutrients are among the many essential processes with positive $\Delta G$ values. Driving these energetically unfavorable steps by coupling them to a spontaneous one is a life-sustaining strategy common to all organisms-animals, plants, and microbes-as you'll see in the Chemical Connections essay.

## Section Summary

The sign of the free energy change, $\Delta G=\Delta H-T \Delta S$, is directly related to reaction spontaneity: a negative $\Delta G$ corresponds to a positive $\Delta S_{\text {univ. }}$ - We use the standard free energy of formation $\left(\Delta G_{f}^{\circ}\right)$ to calculate $\Delta G_{r \times n}^{\circ}$ at $25^{\circ} \mathrm{C}$. - The maximum work a system can do is never obtained from a real (irreversible) process because some free energy is always converted to heat. - The magnitude of $T$ influences the spontaneity of temperature-dependent reactions (same signs of $\Delta H$ and $\Delta S$ ) by affecting the size of $T \Delta S$. For such reactions, the $T$ at which the reaction becomes spontaneous can be estimated by setting $\Delta G=0$. . A nonspontaneous reaction ( $\Delta G>0$ ) can be coupled to a more spontaneous one $(\Delta G \ll 0)$ to make it occur. For example, in organisms, the hydrolysis of ATP drives many reactions with a positive $\Delta G$.

Figure 20.14 The effect of temperature on reaction spontaneity. The two terms that make up $\Delta G$ are plotted against $T$. The figure shows a relatively constant $\Delta H$ and a steadily increasing $T \Delta S$ (and thus more negative $-T \Delta S$ ) for the reaction between $\mathrm{Cu}_{2} \mathrm{O}$ and C . At low $T$, the reaction is nonspontaneous $(\Delta G>0)$ because the positive $\Delta H$ term has a greater magnitude than the negative $T \Delta S$ term. At 352 K , $\Delta H=T \Delta S$, so $\Delta G=0$. At any higher $T$, the reaction becomes spontaneous ( $\Delta G<0$ ) because the $-T \Delta S$ term dominates.

# Chemical Connections to Biological Energetics 

## The Universal Role of ATP

0ne of the most remarkable features of organisms, as well as a strong indication of a common ancestry, is the utilization of the same few biomolecules for all the reactions of life. Despite their incredible diversity of appearance and behavior, virtually all organisms use the same amino acids to make their proteins, the same nucleotides to make their nucleic acids, and the same carbohydrate (glucose) to provide energy.

In addition, all organisms use the same spontaneous reaction to provide the free energy needed to drive a wide variety of nonspontaneous ones. This reaction is the hydrolysis of a high-energy molecule called adenosine triphosphate (ATP) to adenosine diphosphate (ADP):

$$
\begin{array}{r}
\mathrm{ATP}^{4-}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{ADP}^{3-}+\mathrm{HPO}_{4}^{2-}+\mathrm{H}^{+} \\
\Delta G^{\circ \prime}=-30.5 \mathrm{~kJ}
\end{array}
$$

In biochemical systems, the standard-state concentration of $\mathrm{H}^{+}$is $10^{-7} M$, not the usual $1 M$, and the standard free energy change has the symbol $\Delta G^{\circ}$. In the metabolic breakdown of glucose, for example, the initial step is the addition of a phosphate group to a glucose molecule in a dehydration-condensation reaction:
Glucose $+\mathrm{HPO}_{4}^{2-}+\mathrm{H}^{+} \rightleftharpoons$ [glucose phosphate] ${ }^{-}+\mathrm{H}_{2} \mathrm{O}$ $\Delta G^{\circ \prime}=13.8 \mathrm{~kJ}$
Coupling this nonspontaneous reaction to ATP hydrolysis makes the overall process spontaneous. If we add the two reactions, $\mathrm{HPO}_{4}{ }^{2-}, \mathrm{H}^{+}$, and $\mathrm{H}_{2} \mathrm{O}$ cancel, and we obtain

Glucose $+\mathrm{ATP}^{4-} \rightleftharpoons$ [glucose phosphate $]^{-}+\mathrm{ADP}^{3-}$ AnGog-a6.7RJDE
Like the reactions to extract copper that we just discussed, these two reactions cannot affect each other if they are physically separated. Coupling of the reactions is accomplished through an enzyme, a biological catalyst (Section 16.8) that simultaneously
binds glucose and ATP such that the phosphate group of ATP to be transferred lies next to the particular - OH group of glucose that will accept it (Figure B20.3). Enzymes play similar catalytic roles in all the reactions driven by ATP hydrolysis.

The ADP formed in these energy-releasing reactions is combined with phosphate to regenerate ATP in energy-absorbing reactions catalyzed by other enzymes. In fact, one major biochemical reason an organism eats and breathes is to make ATP, so that it has the energy to move, grow, reproduce-and study chemistry, of course. Thus, there is a continuous cycling of ATP to ADP and back to ATP again to supply energy to the cells (Figure B20.4).

Figure B20.4 The cycling of metabolic free energy through ATP. Processes that release free energy are coupled to the formation of ATP from ADP, whereas those that require free energy are coupled to the hydrolysis of ATP to ADP.

Figure B20.3 The coupling of a nonspontaneous reaction to the hydrolysis of ATP. The glucose molecule must lie next to the ATP molecule (shown as ADP-O- $\mathrm{PO}_{3} \mathrm{H}$ ) in the enzyme's active site for the
correct atoms to form bonds. ADP (shown as ADP-OH) and glucose phosphate are released.

What makes ATP hydrolysis such a good supplier of free energy? By examining the phosphate portions of ATP, ADP, and $\mathrm{HPO}_{4}{ }^{2-}$, we can see two reasons (Figure B20.5). The first is that, at physiological $\mathrm{pH}(\sim 7)$, the triphosphate portion of the ATP molecule has an average of four negative charges grouped closely together. As a result, the ATP molecule has a high charge repulsion built into its structure. In ADP, however, this charge repulsion is reduced.

The second reason relates to the greater delocalization of $\pi$ electrons in the hydrolysis products, which we can see from resonance structures. For example, once ATP is hydrolyzed, the $\pi$ electrons in $\mathrm{HPO}_{4}{ }^{2-}$ can be more readily delocalized, which stabilizes the ion. Thus, greater charge repulsion and less electron delocalization make ATP higher in energy than the sum of ADP and $\mathrm{HPO}_{4}{ }^{2-}$. When ATP is hydrolyzed, some of this additional energy is released, to be harnessed by the organism to drive the metabolic reactions that could not otherwise take place.

Figure B20.5 Why is ATP a high-energy molecule? The ATP molecule releases a large amount of free energy when it is hydrolyzed because (A) the high charge repulsion in the triphosphate portion of ATP is reduced, and (B) the free $\mathrm{HPO}_{4}{ }^{2-}$ ion is stabilized by delocalization of its $\pi$ electrons, as shown by these resonance forms.

### 20.4 FREE ENERGY, EQUILIBRIUM, AND REACTION DIRECTION

The sign of $\Delta G$ allows us to predict reaction direction, but it is not the only way to do so. In Chapter 17, we predicted reaction direction by comparing the values of the reaction quotient $(Q)$ and the equilibrium constant $(K)$. Recall that

- If $Q<K(Q / K<1)$, the reaction as written prgceeds to the right.ncer
- If $Q>K(Q / K>1)$, the reactiontionatiten proceeds to the feft.
- If $Q=K(Q / K=1)$, the reaction has reached equilibrium, and there is no net reaction in either direction.
As you might expect, these two ways of predicting reaction spontaneity-the sign of $\Delta G$ and the magnitude of $Q / K$-are related. Their relationship emerges when we compare the signs of $\ln Q / K$ with $\Delta G$ :
- If $Q / K<1$, then $\ln Q / K<0$ : reaction proceeds to the right $(\Delta G<0)$.
- If $Q / K>1$, then $\ln Q / K>0$ : reaction proceeds to the left $(\Delta G>0)$.
- If $Q / K=1$, then $\ln Q / K=0$ : reaction is at equilibrium $(\Delta G=0)$.

Note that the signs of $\Delta G$ and $\ln Q / K$ are identical for a given reaction direction. In fact, $\Delta G$ and $\ln Q / K$ are proportional to each other and made equal through the constant $R T$ :

$$
\begin{equation*}
\Delta G=R T \ln \frac{Q}{K}=R T \ln Q-R T \ln K \tag{20.11}
\end{equation*}
$$

What does this central relationship mean? As you know, $Q$ represents the concentrations (or pressures) of a system's components at any time during the reaction, whereas $K$ represents them when the reaction has reached equilibrium. Therefore, Equation 20.11 says that $\Delta G$ depends on how different the ratio of concentrations, $Q$, is from the equilibrium ratio, $K$.

The last term in Equation 20.11 is very important. By choosing standard-state values for $Q$, we obtain the standard free energy change $\left(\Delta G^{\circ}\right)$. When all concentrations are $1 M$ (or all pressures 1 atm ), $\Delta G$ is $\Delta G^{\circ}$ and $Q$ equals 1:

$$
\Delta G^{\circ}=R T \ln 1-R T \ln K
$$

We know that $\ln 1=0$, so the $R T \ln Q$ term drops out, and we have

$$
\begin{equation*}
\Delta G^{\circ}=-R T \ln K \tag{20.12}
\end{equation*}
$$

Table 20.2 The Relationship Between $\Delta G^{\circ}$ and $K$ at 298 K

| $\Delta G^{\circ}(\mathrm{kJ})$ | $K$ | Significance |  |
| :---: | :---: | :---: | :---: |
| 200 | $9 \times 10^{-36}$ | $\left\{\begin{array}{l} \text { Essentially no forward reaction; } \\ \text { reverse reaction goes to completion } \end{array}\right.$ | \% |
| 100 | $3 \times 10^{-18}$ |  |  |
| 50 | $2 \times 10^{-9}$ |  |  |
| 10 | $2 \times 10^{-2}$ |  |  |
| 1 | $7 \times 10^{-1}$ | $\left\{\begin{array}{l} \text { Forward and reverse reactions proceed } \\ \text { to same extent } \end{array}\right.$ |  |
| 0 | 1 |  |  |
| -1 | 1.5 |  |  |
| -10 | $5 \times 10^{1}$ |  |  |
| -50 | $6 \times 10^{8}$ |  |  |
| -100 | $3 \times 10^{17}$ | $\left\{\begin{array}{l} \text { Forward reaction goes to completion; } \\ \text { essentially no reverse reaction } \end{array}\right.$ |  |
| -200 | $1 \times 10^{35}$ |  |  |

This relationship allows us to calculate the standard free energy change of a reaction $\left(\Delta G^{\circ}\right)$ from its equilibrium constant, or vice versa. Because $\Delta G^{\circ}$ is related logarithmically to $K$, even a small change in the value of $\Delta G^{\circ}$ has a large effect on the value of $K$. Table 20.2 shows the $K$ values that correspond to a range of $\Delta G^{\circ}$ values. Note that as $\Delta G^{\circ}$ becomes more positive, $K$ becomes smaller, which means the reaction reaches equilibrium with less product and more reactant. Similarly, as $\Delta G^{\circ}$ becomes more negative, $K$ becomes larger. For example, if $\Delta G^{\circ}=+10 \mathrm{~kJ}$, $K \approx 0.02$, which means that the product terms are about $\frac{1}{50}$ those of the reactant terms; whereas, if $\Delta G^{\circ}=-10 \mathrm{~kJ}$, they are 50 times larger. Of course, reactions do not usually begin with all components in their standard states. By substituting the redationship between $\Delta G^{\circ}$ and $K$.Equation 20.12) into the expression for $\Delta G$ (Equation 20.1 ), we obtain a relationship that applies to any starting concentrations:

$$
\begin{equation*}
\Delta G=\Delta G^{\circ}+R T \ln Q \tag{20.13}
\end{equation*}
$$

Sample Problems 20.8 and 20.9 illustrate some ways to apply Equations 20.12 and 20.13; the first employs molecular scenes to examine these ideas, while the second highlights an industrial reaction.

SAMPLE PROBLEM 20.8 Using Molecular Scenes to Find $\Delta G$ for a Reaction at Nonstandard Conditions
PROBLEM The molecular scenes below represent three mixtures of $\mathrm{A}_{2}$ (black) and $\mathrm{B}_{2}$ (green) forming AB . Each molecule represents 0.10 mol , and the volume is 1 L . The equation is

$$
\mathrm{A}_{2}(g)+\mathrm{B}_{2}(g) \rightleftharpoons 2 \mathrm{AB}(g) \quad \Delta G^{\circ}=-3.4 \mathrm{~kJ} / \mathrm{mol}
$$

(a) Mixture 1 is at equilibrium; calculate $K$.
(b) Which reaction mixture has the lowest (most negative) $\Delta G$, and which has the highest (most positive)?
(c) Is the reaction spontaneous when $\left[\mathrm{A}_{2}\right]=\left[\mathrm{B}_{2}\right]=[\mathrm{AB}]=1.0 \mathrm{M}$ ?

PLAN (a) Mixture 1 is at equilibrium, so we first write the expression for $Q$ and then find the molarity of each substance from the numbers of molecules to calculate $K$. (b) To find $\Delta G$, we apply Equation 20.13. We are given $\Delta G^{\circ}(-3.4 \mathrm{~kJ} / \mathrm{mol})$, and we know $R(8.314 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{K})$. We calculate $T$ from Equation 20.12 with the value of $K$ that we found in part (a), and substitute the molarity of each substance to get $Q$. (c) The concentration 1.0 M represents
the standard state, and we substitute that concentration into $Q$ in Equation 20.13 and solve for $\Delta G$, which in this case equals $\Delta G^{\circ}$.
SOLUTION (a) Writing the expression for $Q$ and calculating $K$ :

$$
\mathrm{A}_{2}(g)+\mathrm{B}_{2}(g) \rightleftharpoons 2 \mathrm{AB}(g) \quad Q=\frac{[\mathrm{AB}]^{2}}{\left[\mathrm{~A}_{2}\right]\left[\mathrm{B}_{2}\right]} \quad K=\frac{(0.40)^{2}}{(0.20)(0.20)}=4.0
$$

(b) Calculating $T$ from Equation 20.12 for use in Equation 20.13:

$$
\begin{gathered}
\Delta G^{\circ}=-R T \ln K=-\frac{3.4 \mathrm{~kJ}}{\mathrm{~mol}}=-\left(\frac{8.314 \mathrm{~J}}{\mathrm{~mol} \cdot \mathrm{~K}}\right) T \ln 4.0 \\
T=\frac{\frac{-3.4 \mathrm{~kJ}}{\mathrm{~mol}}\left(\frac{1000 \mathrm{~J}}{1 \mathrm{~kJ}}\right)}{-\left(\frac{8.314 \mathrm{~J}}{\mathrm{~mol} \cdot \mathrm{~K}}\right) \ln 4.0}=295 \mathrm{~K}
\end{gathered}
$$

Calculating the value of $\Delta G$ for each mixture from Equation 20.13:
For mixture 1:

$$
\begin{aligned}
\Delta G & =\Delta G^{\circ}+R T \ln Q=-3.4 \mathrm{~kJ}+R T \ln 4.0 \\
& =-3.4 \mathrm{~kJ}\left(\frac{1000 \mathrm{~J}}{1 \mathrm{~kJ}}\right)+\left(\frac{8.314 \mathrm{~J}}{\mathrm{~mol} \cdot \mathrm{~K}}\right)(295 \mathrm{~K}) \ln 4.0 \\
& =-3400 \mathrm{~J}+3400 \mathrm{~J}=0.0 \mathrm{~J}
\end{aligned}
$$

For mixture 2:

$$
\begin{aligned}
& \text { ure 2: } \\
& \qquad \begin{aligned}
\Delta G & =-3.4 \mathrm{~kJ}+R T \ln \frac{(0.20)^{2}}{(0.30)(0.30)} \\
& =-3.4 \mathrm{~kJ}\left(\frac{1000 \mathrm{~J}}{1 \mathrm{~kJ}}\right)+\left(\frac{8.314 \mathrm{~J}}{\mathrm{~mol} \cdot \mathrm{~K}}\right)(295 \mathrm{~K}) \ln 0.44=-5.4 \times 10^{3} \mathrm{~J}
\end{aligned}
\end{aligned}
$$

For mixture 3:

$$
\begin{aligned}
\Delta G & =-3.4 \mathrm{~kJ} / \mathrm{mol}+R T \ln \frac{(0.60)^{2}}{(0.10)(0.10)} \\
& =-3.4 \mathrm{~kJ} / \mathrm{mol}\left(\frac{1000 \mathrm{~J}}{1 \mathrm{~kJ}}\right)+\left(\frac{8.314 \mathrm{~J}}{\mathrm{~mol} \cdot \mathrm{~K}}\right)(295 \mathrm{~K}) \ln 36=5.4 \times 10^{3} \mathrm{~J}
\end{aligned}
$$

Mixture 2 has the most negative $\Delta G$, and mixture 3 has the most positive $\Delta G$.
(c) Finding $\Delta G$ when $\left[\mathrm{A}_{2}\right]=\left[\mathrm{B}_{2}\right]=[\mathrm{AB}]=1.0 \mathrm{M}$ :

$$
\begin{aligned}
& \Delta G
\end{aligned}=\Delta G^{\circ}+R T \ln Q=-3.4 \mathrm{~kJ} / \mathrm{mol}+R T \ln \frac{(1.0)^{2}}{(1.0)(1.0)}
$$

Yes, the reaction is spontaneous when the components are in their standard states.
CHECK In (b), round to check the arithmetic; for example, for mixture 3,

$$
\Delta G \approx-3000 \mathrm{~J}+(8 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})(300 \mathrm{~K}) 4 \approx 7000 \mathrm{~J}
$$

which is in the correct ballpark.
COMMENT 1. By using the properties of logarithms, we didn't have to calculate $T$ and $\Delta G$ in (b). In mixture $2, Q<1$, so $\ln Q$ is negative, which makes $\Delta G$ more negative. Also, note that $Q(0.44)<K(4.0)$, so $\Delta G<0$. In mixture $3, Q>1$ (and is greater than it is in mixture 1), so $\ln Q$ is positive, which makes $\Delta G$ positive. Also, $Q(36)>K(4.0)$, so $\Delta G>0$. 2. In (b), the value of zero for $\Delta G$ of the equilibrium mixture (mixture 1) makes sense, because a system at equilibrium has released all of its free energy.
FOLLOW-UP PROBLEM 20.8 The scenes below depict mixtures of $X_{2}(\tan )$ and $\mathrm{Y}_{2}$ (blue) forming $\mathrm{XY}_{2}$. Each molecule represents 0.10 mol , and the volume is 1 L . The equation is $\mathrm{X}_{2}(g)+2 \mathrm{Y}_{2}(g) \rightleftharpoons 2 \mathrm{XY}_{2}(g) ; \Delta G^{\circ}=-1.3 \mathrm{~kJ} / \mathrm{mol}$.

(a) If $K=2$, which mixture is at equilibrium? (b) Rank the three mixtures from the lowest (most negative) $\Delta G$ to highest (most positive) $\Delta G$. (c) What is the sign of $\Delta G$ for the change that occurs as each nonequilibrium mixture approaches equilibrium?

## SAMPLE PROBLEM 20.9 Calculating $\Delta G$ at Nonstandard Conditions

PROBLEM The oxidation of $\mathrm{SO}_{2}(\mathrm{~g})$ (which we considered in Sample Problem 20.7),

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{SO}_{3}(g)
$$

is too slow at 298 K to be useful in the manufacture of sulfuric acid. To overcome this low rate, the process is conducted at an elevated temperature.
(a) Calculate $K$ at 298 K and at 973 K . $\left(\Delta G_{298}^{\circ}=-141.6 \mathrm{~kJ} / \mathrm{mol}\right.$ for reaction as written; using $\Delta H^{\circ}$ and $\Delta S^{\circ}$ values at $973 \mathrm{~K}, \Delta G_{973}^{\circ}=-12.12 \mathrm{~kJ} / \mathrm{mol}$ for reaction as written.)
(b) In experiments to determine the effect of temperature on reaction spontaneity, two sealed containers are filled with 0.500 atm of $\mathrm{SO}_{2}, 0.0100 \mathrm{~atm}$ of $\mathrm{O}_{2}$, and 0.100 atm of $\mathrm{SO}_{3}$ and kept at $25^{\circ} \mathrm{C}$ and at $700 .{ }^{\circ} \mathrm{C}$. In which direction, if any, will the reaction proceed to reach equilibrium at each temperature?
(c) Calculate $\Delta G$ for the system in part (b) at each temperature.

PLAN (a) We know $\Delta G^{\circ}, T$, and $R$, so we can calculate the $K$ 's from Equation 20.12. (b) To determine if a net reaction will occur at the given pressures, we calculate $Q$ with the given partial pressures and compare it with each $K$ from part (a). (c) Because these are not standard-state pressures, we calculate $\Delta G$ at each $T$ from Equation 20.13 with the values of $\Delta G^{\circ}$ (given) and $Q$ [found in part (b)].
SOLUTION (a) Calculating $K$ at the two temperatures:

$$
\Delta G^{\circ}=-R T \ln K
$$

so

$$
K=e^{-\left(\Delta G^{\circ} / R T\right)}
$$

At 298 K , the exponent is

$$
-\left(\Delta G^{\circ} / R T\right)=-\left(\frac{-141.6 \mathrm{~kJ} / \mathrm{mol} \times \frac{1000 \mathrm{~J}}{1 \mathrm{~kJ}}}{8.314 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K} \times 298 \mathrm{~K}}\right)=57.2
$$

so

$$
K=e^{-\left(\Delta G^{\circ} / R T\right)}=e^{57.2}=7 \times 10^{24}
$$

At 973 K , the exponent is

$$
-\left(\Delta G^{\circ} / R T\right)=-\left(\frac{-12.12 \mathrm{~kJ} / \mathrm{mol} \times \frac{1000 \mathrm{~J}}{1 \mathrm{~kJ}}}{8.314 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K} \times 973 \mathrm{~K}}\right)=1.50
$$

so

$$
K=e^{-\left(\Delta G^{\circ} / R T\right)}=e^{1.50}=4.5
$$

(b) Calculating the value of $Q$ :

$$
Q=\frac{P_{\mathrm{SO}_{3}}^{2}}{P_{\mathrm{SO}_{2}}^{2} \times P_{\mathrm{O}_{2}}}=\frac{0.100^{2}}{0.500^{2} \times 0.0100}=4.00
$$

Because $Q<K$ at both temperatures, the denominator will decrease and the numerator increase-more $\mathrm{SO}_{3}$ will form-until $Q$ equals $K$. However, the reaction will go far to the right at 298 K while approaching equilibrium, whereas it will move only slightly to the right at 973 K .
(c) Calculating $\Delta G$, the nonstandard free energy change, at 298 K :

$$
\begin{aligned}
\Delta G_{298} & =\Delta G^{\circ}+R T \ln Q \\
& =-141.6 \mathrm{~kJ} / \mathrm{mol}+\left(8.314 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K} \times \frac{1 \mathrm{~kJ}}{1000 \mathrm{~J}} \times 298 \mathrm{~K} \times \ln 4.00\right) \\
& =-138.2 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

Calculating $\Delta G$ at 973 K :

$$
\begin{aligned}
\Delta G_{973} & =\Delta G^{\circ}+R T \ln Q \\
& =-12.12 \mathrm{~kJ} / \mathrm{mol}+\left(8.314 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K} \times \frac{1 \mathrm{~kJ}}{1000 \mathrm{~J}} \times 973 \mathrm{~K} \times \ln 4.00\right) \\
& =-0.9 \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

CHECK Note that in parts (a) and (c) we made the energy units in free energy changes (kJ) consistent with those in $R(\mathrm{~J})$. Based on the rules for significant figures in addition and subtraction, we retain one digit to the right of the decimal place in part (c).
COMMENT For these starting gas pressures at 973 K , the process is barely spontaneous ( $\Delta G=-0.9 \mathrm{~kJ} / \mathrm{mol}$ ), so why use a higher temperature? Like the synthesis of $\mathrm{NH}_{3}$ (Chemical Connections, p. 771), this process is carried out at a higher temperature with a catalyst to attain a higher rate, even though the yield is greater at a lower temperature. We discuss the details of the industrial production of sulfuric acid in Chapter 22.
FOLLOW-UP PROBLEM 20.9 At 298 K, hypobromous acid ( HBrO ) dissociates in water with a $K_{\mathrm{a}}$ of $2.3 \times 10^{-9}$.
(a) Calculate $\Delta G^{\circ}$ for the dissociation of HBrO .
(b) Calculate $\Delta G$ if $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=6.0 \times 10^{-4} \mathrm{M},\left[\mathrm{BrO}^{-}\right]=0.10 \mathrm{M}$, and $[\mathrm{HBrO}]=0.20 \mathrm{M}$.

Another Look at the Meaning of Spontaneity At this point, let's discuss some terminology related to, but distinct from, the terms spontaneous and nonspontaneous. Consider the general reaction $\mathrm{A} \rightleftharpoons \mathrm{B}$, for which $K=[\mathrm{B}] /[\mathrm{A}]>1$, and therefore, the reaction proceeds largely from left to right (Figure 20.15A). From pure A to the equilibrium point, $Q<K$ and the curved green arrow indicates that the reaction is spontaneous $(\Delta G<0)$. From there on, the curved red arrow shows that the reaction is nonspontaneous $(\Delta G>0)$. From pure B to the equilibrium point, $Q>K$ and the reaction is also spontaneous ( $\Delta G<0$ ), but not thereafter. In either case, the free energy decreases as the reaction proceeds, until it reaches a minimum at the equilibrium mixture: $Q=K$ and $\Delta G=0$. For the overall reaction $\mathrm{A} \rightleftharpoons \mathrm{B}$ (starting with all components in their standard states), $G_{\mathrm{B}}^{\circ}$ is smaller than $G_{\mathrm{A}}^{\circ}$, so $\Delta G^{\circ}$ is negative, which corresponds to $K>1$. We call this a product-favored reaction because the final state of the system contains mostly product. Apago PDF Fnhancer

Now consider the opposite situation, a general reaction $\mathrm{C} \rightleftharpoons \mathrm{D}$, for which $K=[\mathrm{D}] /[\mathrm{C}]<1$ : the reaction proceeds only slightly from left to right (Figure 20.15B). Here, too, whether we start with pure C or pure D, the reaction is spontaneous ( $\Delta G<0$ ) until the equilibrium point. But here, the equilibrium mixture contains mostly C (the reactant), so we say the reaction is reactant favored. In this case, $G_{\mathrm{D}}^{\circ}$ is larger than $G_{\mathrm{C}}^{\circ}$, so $\Delta G^{\circ}$ is positive, which corresponds to $K<1$. The point is that spontaneous refers to that portion of a reaction in which the free energy is decreasing, that is, from some starting mixture to the equilibrium mixture, whereas product-favored refers to a reaction that goes predominantly, but not necessarily completely, to product (see Table 20.2).

Figure 20.15 The relation between free energy and the extent of reaction. The free energy of the system is plotted against the extent of reaction. Each reaction proceeds spontaneously $(Q \neq K$ and $\Delta G<0$; curved green arrows) from either pure reactants (A or C) or pure products ( $B$ or $D$ ) to the equilibrium mixture, at which point $\Delta G=0$. The reaction from the equilibrium mixture to either pure reactants or products is nonspontaneous ( $\Delta G>0$; curved red arrows). A, For the product-favored reaction $A \rightleftharpoons B$, $G_{A}^{\circ}>G_{B}^{\circ}$, so $\Delta G^{\circ}<0$ and $K>1$. B, For the reactant-favored reaction $C \rightleftharpoons D$, $G_{D}^{\circ}>G_{C}^{\circ}$, so $\Delta G^{\circ}>0$ and $K<1$.

## Section Summary

Two ways of predicting reaction direction are from the value of $\Delta G$ and from the relation of $Q$ to $K$. These variables represent different aspects of the same phenomenon and are related to each other by $\Delta G=R T \ln Q / K$. When $Q=K$, the system can release no more free energy. - Beginning with $Q$ at the standard state, the free energy change is $\Delta G^{\circ}$, and it is related to the equilibrium constant by $\Delta G^{\circ}=-R T \ln K$. - Any nonequilibrium mixture of reactants and products moves spontaneously $(\Delta G<0)$ toward the equilibrium mixture. - A product-favored reaction goes predominantly toward product and, thus, has $K>1$ and $\Delta G^{\circ}<0$.

## Chapter Perspective

As processes move toward equilibrium, some of the energy released becomes degraded to unusable heat, and the entropy of the universe increases. This unalterable necessity built into all natural processes has led to speculation about the "End of Everything," when all possible processes have stopped occurring, no free energy remains in any system, and nothing but waste heat is dispersed evenly throughout the universe-the final equilibrium! Even if this grim future is in store, however, it is many billions of years away, so you have plenty of time to appreciate more hopeful applications of thermodynamics. In Chapter 21, you'll see how spontaneous reactions can generate electricity and how electricity supplies free energy to drive nonspontaneous ones.

## CHAPTER REVIEW GUIDE

The following sections provide many aids to help you study this chapter. (Numbers in parentheses refer to pages, unless noted otherwise.)

## Learning Objectives These are concepts and skills you should know after studying this chapter.

Relevant section and/or sample problem (SP) numbers appear in parentheses.

## Understand These Concepts

1. How the tendency of a process to occur by itself is distinct from how long it takes to occur (Introduction)
2. The distinction between a spontaneous and a nonspontaneous change (Section 20.1)
3. Why the first law of thermodynamics and the sign of $\Delta H^{\circ}$ cannot predict the direction of a spontaneous process (Section 20.1)
4. How the entropy $(S)$ of a system is defined by the number of microstates over which its energy is dispersed (Section 20.1)
5. How entropy is alternatively defined by the heat absorbed (or released) at constant $T$ in a reversible process (Section 20.1)
6. The criterion for spontaneity according to the second law of thermodynamics: that a change increases $S_{\text {univ }}$ (Section 20.1)
7. How absolute values of standard molar entropies $\left(S^{\circ}\right)$ can be obtained because the third law of thermodynamics provides a "zero point" (Section 20.1)
8. How temperature, physical state, dissolution, atomic size, and molecular complexity influence $S^{\circ}$ values (Section 20.1)
9. How $\Delta S_{\mathrm{rxn}}^{\circ}$ is based on the difference between the summed $S^{\circ}$ values for the reactants and those for products (Section 20.2)
10. How the surroundings add heat to or remove heat from the system and how $\Delta S_{\text {surr }}$ influences overall $\Delta S_{\mathrm{rxn}}^{\circ}$ (Section 20.2)
11. The relationship between $\Delta S_{\text {surr }}$ and $\Delta H_{\text {sys }}$ (Section 20.2)
12. How reactions proceed spontaneously toward equilibrium $\left(\Delta S_{\text {univ }}>0\right)$ but proceed no further at equilibrium $\left(\Delta S_{\text {univ }}=0\right)$ (Section 20.2)
13. How the free energy change $(\Delta G)$ combines the system's entropy and enthalpy changes (Section 20.3)
14. How the expression for the free energy change is derived from the second law (Section 20.3)
15. The relationship between $\Delta G$ and the maximum work a system can perform and why this quantity of work is never performed in a real process (Section 20.3)
16. How temperature determines spontaneity for reactions in which $\Delta S$ and $\Delta H$ have the same sign (Section 20.3)
17. Why the temperature at which a reaction becomes spontaneous occurs when $\Delta G=0$ (Section 20.3)
18. How a spontaneous change can be coupled to a nonspontaneous change to make it occur (Section 20.3)
19. How $\Delta G$ is related to the ratio of $Q$ to $K$ (Section 20.4)
20. The meaning of $\Delta G^{\circ}$ and its relation to $K$ (Section 20.4)
21. The relation of $\Delta G$ to $\Delta G^{\circ}$ and $Q$ (Section 20.4)
22. Why $G$ decreases, no matter what the starting concentrations, as the reacting system moves toward equilibrium (Section 20.4)

## Master These Skills

1. Predicting relative $S^{\circ}$ values of systems (Section 20.1 and SP 20.1)
2. Calculating $\Delta S_{\mathrm{rxn}}^{\circ}$ for a chemical change (SP 20.2)
3. Finding reaction spontaneity from $\Delta S_{\text {surr }}$ and $\Delta H_{\text {sys }}^{\circ}$ (SP 20.3)
4. Calculating $\Delta G_{\mathrm{rxn}}^{\circ}$ from $\Delta H_{\mathrm{f}}^{\circ}$ and $S^{\circ}$ values (SP 20.4)
5. Calculating $\Delta G_{\mathrm{rxn}}^{\circ}$ from $\Delta G_{\mathrm{f}}^{\circ}$ values (SP 20.5)
6. Predicting the signs of $\Delta H, \Delta S$, and $\Delta G$ (SP 20.6)
7. Calculating the effect of temperature on $\Delta G$ (SP 20.7)
8. Calculating the temperature at which a reaction becomes spontaneous (Section 20.3)
9. Calculating $K$ from $\Delta G^{\circ}$ (Section 20.4 and SP 20.9)
10. Using $\Delta G^{\circ}$ and $Q$ to calculate $\Delta G$ at any conditions (SPs 20.8, 20.9)

Key Terms These important terms appear in boldface in the chapter and are defined again in the Glossary.

## Section 20.1

spontaneous change (881)
entropy ( $S$ ) (884)
second law of thermodynamics (887)
third law of thermodynamics (888)
standard molar entropy ( $S^{\circ}$ ) (888)

## Section 20.2

standard entropy of reaction ( $\Delta S_{\mathrm{rxn}}^{\circ}$ ) (893)

## Section 20.3

free energy $(G)$ (899)
standard free energy change ( $\Delta G^{\circ}$ ) (900)
standard free energy of formation ( $\Delta G_{\mathrm{f}}^{\circ}$ ) (901)
coupling of reactions (907) adenosine triphosphate (ATP) (908)

Key Equations and Relationships Numbered and screened concepts are listed for you to refer to or memorize.
20.1 Quantifying entropy in terms of the number of microstates $(W)$ over which the energy of a system can be distributed (884):

$$
S=k \ln W
$$

20.2 Quantifying the entropy change in terms of heat absorbed (or released) in a reversible process (887)

$$
\Delta S_{\mathrm{sys}}=\frac{q_{\mathrm{rev}}}{T}
$$

20.3 Stating the second law of thermodynamics, for a spontaneous process (888):

$$
\Delta S_{\text {univ }}=\Delta S_{\text {sys }}+\Delta S_{\text {surr }}>0
$$

20.4 Calculating the standard entropy of reaction from the standard molar entropies of reactants and products (894):

$$
\Delta S_{\mathrm{rxn}}^{\circ}=\Sigma m S_{\text {products }}^{\circ}-\Sigma n S_{\text {reactants }}^{\circ}
$$

20.5 Relating the entropy change in the surroundings to the enthalpy change of the system and the temperature (895):

$$
\Delta S_{\text {surr }}=-\frac{\Delta H_{\text {sys }}}{T}
$$

20.6 Expressing the free energy change ef the systernn termbe of its component enthalpy and entropy changes (Gibbs equation) (900):

$$
\Delta G_{\mathrm{sys}}=\Delta H_{\mathrm{sys}}-T \Delta S_{\mathrm{sys}}
$$

20.7 Calculating the standard free energy change from standard enthalpy and entropy changes (900):

$$
\Delta G_{\mathrm{sys}}^{\circ}=\Delta H_{\mathrm{sys}}^{\circ}-T \Delta S_{\mathrm{sys}}^{\circ}
$$

20.8 Calculating the standard free energy change from the standard free energies of formation (901):

$$
\Delta G_{\mathrm{rxn}}^{\circ}=\sum m \Delta G_{\mathrm{f}(\text { products })}^{\circ}-\Sigma n \Delta G_{\mathrm{f}(\text { reactants })}^{\circ}
$$

20.9 Relating the free energy change to the maximum work a process can perform (902):

$$
\Delta G=w_{\max }
$$

20.10 Finding the temperature at which a reaction becomes spontaneous (906):

$$
T=\frac{\Delta H}{\Delta S}
$$

20.11 Expressing the free energy change in terms of $Q$ and $K$ (909):

$$
\Delta G=R T \ln \frac{Q}{K}=R T \ln Q-R T \ln K
$$

20.12 Expressing the free energy change when $Q$ is at standard state conditions (909):
F』hancer $\Delta G^{\circ}=-R T \ln K$
20.13 Expressing the free energy change for nonstandard initial conditions (910):

$$
\Delta G=\Delta G^{\circ}+R T \ln Q
$$

Highlighted Figures and Tables These figures ( F ) and tables ( T ) provide a visual review of key ideas.

Brief Solutions to FOLLOW-UP PROBLEMS Compare your solutions to these calculation steps and answers.
20.1 (a) $\mathrm{PCl}_{5}(g)$ : higher molar mass and more complex molecule; (b) $\mathrm{BaCl}_{2}(s)$ : higher molar mass; (c) $\mathrm{Br}_{2}(g)$ : gases have more freedom of motion and dispersal of energy than liquids.

$$
\begin{aligned}
& \mathbf{2 0 . 2}(\mathrm{a}) 2 \mathrm{NaOH}(s)+\mathrm{CO}_{2}(g) \longrightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l) \\
& \Delta n_{\text {gas }}=-1, \text { so } \Delta S_{\mathrm{rxn}}^{\circ}<0 \\
& \Delta S_{\mathrm{rxn}}^{\circ}= {[(1 \mathrm{~mol} \mathrm{H}} \\
&\left.+\left(1 \mathrm{Hol} \mathrm{Na}_{2} \mathrm{O}\right)(69.9 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})(139 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})\right] \\
&+\left(\left(1 \mathrm{~mol} \mathrm{CO}_{2}\right)(213.7 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})\right. \\
&-(2 \mathrm{~mol} \mathrm{NaOH})(64.5 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})] \\
&=-134 \mathrm{~J} / \mathrm{K} \\
&(\mathrm{~b}) 2 \mathrm{Fe}(s)+3 \mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{Fe}_{2} \mathrm{O}_{3}(s)+3 \mathrm{H}_{2}(g) \\
& \Delta n_{\text {gas }}= 0, \text { so cannot predict sign of } \Delta S_{\mathrm{rxn}}^{\circ} \\
& \Delta S_{\mathrm{rxn}}^{\circ}= {\left[\left(1 \mathrm{~mol} \mathrm{Fe}_{2} \mathrm{O}_{3}\right)(87.4 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})\right.} \\
&\left.+\left(3 \mathrm{~mol} \mathrm{H}_{2}\right)(130.6 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})\right] \\
&-\left[\left(2 \mathrm{~mol} \mathrm{Fe}^{\circ}\right)(27.3 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})\right. \\
&\left.+\left(3 \mathrm{~mol} \mathrm{H}_{2} \mathrm{O}\right)(188.7 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})\right] \\
&=-141.5 \mathrm{~J} / \mathrm{K}
\end{aligned}
$$

$$
\begin{aligned}
& 20.32 \mathrm{FeO}(s)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{Fe}_{2} \mathrm{O}_{3}(s) \\
& \Delta S_{\text {sys }}^{\circ}=\left(1 \mathrm{~mol} \mathrm{Fe}_{2} \mathrm{O}_{3}\right)(87.4 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K}) \\
& -[(2 \mathrm{~mol} \mathrm{FeO})(60.75 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K}) \\
& \left.+\left(\frac{1}{2} \mathrm{~mol} \mathrm{O}_{2}\right)(205.0 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{~K})\right] \\
& =-136.6 \mathrm{~J} / \mathrm{K} \\
& \Delta H_{\text {sys }}^{\circ}=\left(1 \mathrm{~mol} \mathrm{Fe}_{2} \mathrm{O}_{3}\right)(-825.5 \mathrm{~kJ} / \mathrm{mol}) \\
& -\left[(2 \mathrm{~mol} \mathrm{FeO})(-272.0 \mathrm{~kJ} / \mathrm{mol})+\left(\frac{1}{2} \mathrm{~mol} \mathrm{O}_{2}\right)(0 \mathrm{~kJ} / \mathrm{mol})\right] \\
& =-281.5 \mathrm{~kJ} \\
& \Delta S_{\text {surr }}=-\frac{\Delta H_{\text {sys }}^{\circ}}{T}=-\frac{(-281.5 \mathrm{~kJ} \times 1000 \mathrm{~J} / \mathrm{kJ})}{298 \mathrm{~K}}=+945 \mathrm{~J} / \mathrm{K} \\
& \Delta S_{\text {univ }}=\Delta S_{\text {sys }}^{\circ}+\Delta S_{\text {surr }}=-136.6 \mathrm{~J} / \mathrm{K}+945 \mathrm{~J} / \mathrm{K} \\
& =808 \mathrm{~J} / \mathrm{K} \text {; reaction is spontaneous at } 298 \mathrm{~K} \text {. } \\
& \text { 20.4 Using } \Delta H_{\mathrm{f}}^{\circ} \text { and } S^{\circ} \text { values from Appendix B, } \\
& \Delta H_{\mathrm{rxn}}^{\circ}=-114.2 \mathrm{~kJ} \text { and } \Delta S_{\mathrm{rxn}}^{\circ}=-146.5 \mathrm{~J} / \mathrm{K} \\
& \Delta G_{\mathrm{rxn}}^{\circ}=\Delta H_{\mathrm{rxn}}^{\circ}-T \Delta S_{\mathrm{rxn}}^{\circ} \\
& =-114.2 \mathrm{~kJ}-[(298 \mathrm{~K})(-146.5 \mathrm{~J} / \mathrm{K})(1 \mathrm{~kJ} / 1000 \mathrm{~J})] \\
& =-70.5 \mathrm{~kJ}
\end{aligned}
$$

## Brief Solutions to FOLLOW-UP PROBLEMS (continued)

20.5 (a) $\Delta G_{\mathrm{rxn}}^{\circ}=\left(2 \mathrm{~mol} \mathrm{NO}_{2}\right)(51 \mathrm{~kJ} / \mathrm{mol})$
$-[(2 \mathrm{~mol} \mathrm{NO})(86.60 \mathrm{~kJ} / \mathrm{mol})$
$\left.+\left(1 \mathrm{~mol} \mathrm{O}_{2}\right)(0 \mathrm{~kJ} / \mathrm{mol})\right]$
$=-71 \mathrm{~kJ}$
(b) $\Delta G_{\text {rxn }}^{\circ}=(2 \mathrm{~mol} \mathrm{CO})(-137.2 \mathrm{~kJ} / \mathrm{mol})-[(2 \mathrm{~mol} \mathrm{C})(0 \mathrm{~kJ} / \mathrm{mol})$ $\left.+\left(1 \mathrm{~mol} \mathrm{O}_{2}\right)(0 \mathrm{~kJ} / \mathrm{mol})\right]$

$$
=-274.4 \mathrm{~kJ}
$$

20.6 (a) More moles of gas are present after the reaction, so $\Delta S>0$.
(b) The problem says the reaction is spontaneous $(\Delta G<0)$ only above $325^{\circ} \mathrm{C}$, which implies high $T$. If $\Delta S>0,-T \Delta S<0$, so $\Delta G$ will become negative at higher $T$ only if $\Delta H>0$.
$20.7 \Delta G$ becomes negative at lower $T$, so $\Delta H<0, \Delta S<0$, and $-T \Delta S>0$. At lower $T$, the negative $\Delta H$ value becomes larger than the positive $-T \Delta S$ value.
20.8 (a) Mixture 2 is at equilibrium. (b) 3 (most negative) $<2<1$ (most positive). (c) Any reaction mixture moves spontaneously toward equilibrium, so both changes have a negative $\Delta G$.
20.9 (a) $\begin{aligned} \Delta G^{\circ}=-R T \ln K= & -8.314 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{K} \times \frac{1 \mathrm{~kJ}}{1000 \mathrm{~J}} \times 298 \mathrm{~K} \\ & \times \ln \left(2.3 \times 10^{-9}\right)\end{aligned}$

$$
=49 \mathrm{~kJ} / \mathrm{mol}
$$

(b) $Q=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{BrO}^{-}\right]}{[\mathrm{HBrO}]}=\frac{\left(6.0 \times 10^{-4}\right)(0.10)}{0.20}=3.0 \times 10^{-4}$
$\Delta G=\Delta G^{\circ}+R T \ln Q$
$=49 \mathrm{~kJ} / \mathrm{mol}$
$+\left[8.314 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{K} \times \frac{1 \mathrm{~kJ}}{1000 \mathrm{~J}} \times 298 \mathrm{~K} \times \ln \left(3.0 \times 10^{-4}\right)\right]$
$=29 \mathrm{~kJ} / \mathrm{mol}$

## PROBLEMS

Problems with colored numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and provide the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

Apago PDF
Note: Unless stated otherwise, problems refer to systems at $298 \mathrm{~K}\left(25^{\circ} \mathrm{C}\right)$. Solving these problems may require values from Appendix B.

## The Second Law of Thermodynamics: Predicting Spontaneous Change <br> (Sample Problem 20.1)

## Concept Review Questions

20.1 Distinguish between the terms spontaneous and instantaneous. Give an example of a process that is spontaneous but very slow, and one that is very fast but not spontaneous.
20.2 Distinguish between the terms spontaneous and nonspontaneous. Can a nonspontaneous process occur? Explain.
20.3 State the first law of thermodynamics in terms of (a) the energy of the universe; (b) the creation or destruction of energy; (c) the energy change of system and surroundings. Does the first law reveal the direction of spontaneous change? Explain.
20.4 State qualitatively the relationship between entropy and freedom of particle motion. Use this idea to explain why you will probably never (a) be suffocated because all the air near you has moved to the other side of the room; (b) see half the water in your cup of tea freeze while the other half boils.
20.5 Why is $\Delta S_{\text {vap }}$ of a substance always larger than $\Delta S_{\text {fus }}$ ?
20.6 How does the entropy of the surroundings change during an exothermic reaction? An endothermic reaction? Other than the examples in text, describe a spontaneous endothermic process.
20.7 (a) What is the entropy of a perfect crystal at 0 K ?
(b) Does entropy increase or decrease as the temperature rises?
(c) Why is $\Delta H_{\mathrm{f}}^{\circ}=0$ but $S^{\circ}>0$ for an element?
(d) Why does Appendix B list $\Delta H_{\mathrm{f}}^{\circ}$ values but not $\Delta S_{\mathrm{f}}^{\circ}$ values?

Skill-Building Exercises (grouped in similar pairs)
20.8 Which of the following processes are spontaneous?
(a) Water evaporates from a puddle. (b) A lion chases an antelope.
(c) An isotope undergoes radioactive disintegration.
20.9 Which of the following processes are spontaneous?
(a) Eath moves fround the Sun. (b) A boulder rolls up a hill. (c) Sodium metal and chlorine gas form solid sodium chloride.
20.10 Which of the following processes are spontaneous?
(a) Methane burns in air. (b) A teaspoonful of sugar dissolves in a cup of hot coffee. (c) A soft-boiled egg becomes raw.
20.11 Which of the following processes are spontaneous?
(a) A satellite falls to Earth. (b) Water decomposes to $\mathrm{H}_{2}$ and $\mathrm{O}_{2}$ at 298 K and 1 atm . (c) Average car prices increase.
20.12 Predict the sign of $\Delta S_{\text {sys }}$ for each process: (a) A piece of wax melts. (b) Silver chloride precipitates from solution. (c) Dew forms on a lawn in morning.
20.13 Predict the sign of $\Delta S_{\text {sys }}$ for each process: (a) Gasoline vapors mix with air in a car engine. (b) Hot air expands. (c) Humidity condenses in cold air.
20.14 Predict the sign of $\Delta S_{\text {sys }}$ for each process: (a) Alcohol evaporates. (b) A solid explosive converts to a gas. (c) Perfume vapors diffuse through a room.
20.15 Predict the sign of $\Delta S_{\text {sys }}$ for each process: (a) A pond freezes in winter. (b) Atmospheric $\mathrm{CO}_{2}$ dissolves in the ocean. (c) An apple tree bears fruit.
20.16 Without using Appendix B, predict the sign of $\Delta S^{\circ}$ for
(a) $2 \mathrm{~K}(s)+\mathrm{F}_{2}(g) \longrightarrow 2 \mathrm{KF}(s)$
(b) $\mathrm{NH}_{3}(g)+\mathrm{HBr}(g) \longrightarrow \mathrm{NH}_{4} \operatorname{Br}(s)$
(c) $\mathrm{NaClO}_{3}(s) \longrightarrow \mathrm{Na}^{+}(a q)+\mathrm{ClO}_{3}^{-}(a q)$
20.17 Without using Appendix B , predict the sign of $\Delta S^{\circ}$ for
(a) $\mathrm{H}_{2} \mathrm{~S}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \frac{1}{8} \mathrm{~S}_{8}(s)+\mathrm{H}_{2} \mathrm{O}(g)$
(b) $\mathrm{HCl}(a q)+\mathrm{NaOH}(a q) \longrightarrow \mathrm{NaCl}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$
(c) $2 \mathrm{NO}_{2}(g) \longrightarrow \mathrm{N}_{2} \mathrm{O}_{4}(g)$
20.18 Without using Appendix B, predict the sign of $\Delta S^{\circ}$ for
(a) $\mathrm{CaCO}_{3}(s)+2 \mathrm{HCl}(a q) \longrightarrow \mathrm{CaCl}_{2}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g)$
(b) $2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)$
(c) $2 \mathrm{KClO}_{3}(s) \longrightarrow 2 \mathrm{KCl}(s)+3 \mathrm{O}_{2}(g)$
20.19 Without using Appendix B, predict the sign of $\Delta S^{\circ}$ for
(a) $\mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{AgCl}(s)$
(b) $\mathrm{KBr}(s) \longrightarrow \mathrm{KBr}(a q)$
(c)

20.20 Predict the sign of $\Delta S$ for each process:
(a) $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(\mathrm{g})$ ( 350 K and 500 torr) $\longrightarrow$
$\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(\mathrm{g})(350 \mathrm{~K}$ and 250 torr $)$
(b) $\mathrm{N}_{2}(\mathrm{~g})(298 \mathrm{~K}$ and 1 atm$) \longrightarrow \mathrm{N}_{2}(\mathrm{aq})$ (298 K and 1 atm$)$
(c) $\mathrm{O}_{2}(\mathrm{aq})(303 \mathrm{~K}$ and 1 atm$) \longrightarrow \mathrm{O}_{2}(\mathrm{~g})(303 \mathrm{~K}$ and 1 atm$)$
20.21 Predict the sign of $\Delta S$ for each process:
(a) $\mathrm{O}_{2}(\mathrm{~g})(1.0 \mathrm{~L}$ at 1 atm$) \longrightarrow \mathrm{O}_{2}(\mathrm{~g})(0.10 \mathrm{~L}$ at 10 atm$)$
(b) $\mathrm{Cu}(s)\left(350^{\circ} \mathrm{C}\right.$ and 2.5 atm$) \longrightarrow \mathrm{Cu}(s)\left(450^{\circ} \mathrm{C}\right.$ and 2.5 atm$)$
(c) $\mathrm{Cl}_{2}(\mathrm{~g})\left(100^{\circ} \mathrm{C}\right.$ and 1 atm$) \longrightarrow \mathrm{Cl}_{2}(\mathrm{~g})\left(10^{\circ} \mathrm{C}\right.$ and 1 atm$)$
20.22 Predict which substance has greater molar entropy. Explain.
(a) Butane $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}(\mathrm{~g})$ or 2-butene $\mathrm{CH}_{3} \mathrm{CH}=\mathrm{CHCH}_{3}(\mathrm{~g})$
(b) $\mathrm{Ne}(g)$ or $\mathrm{Xe}(g)$
(c) $\mathrm{CH}_{4}(g)$ or $\mathrm{CCl}_{4}(l)$
20.23 Predict which substance has greater molar entropy. Explain.
(a) $\mathrm{NO}_{2}(g)$ or $\mathrm{N}_{2} \mathrm{O}_{4}(g)$
(b) $\mathrm{CH}_{3} \mathrm{OCH}_{3}(l)$ or $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}(l)$
(c) $\mathrm{HCl}(g)$ or $\mathrm{HBr}(g)$
20.24 Predict which substance has greater molar entropy. Explain.
(a) $\mathrm{CH}_{3} \mathrm{OH}(l)$ or $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)$
(b) $\mathrm{KClO}_{3}(s)$ or $\mathrm{KClO}_{3}(a q)$
(c) $\mathrm{Na}(s)$ or $\mathrm{K}(s)$
20.25 Predict which substance has greaternotanfopy. Explain.
(a) $\mathrm{P}_{4}(g)$ or $\mathrm{P}_{2}(g)$
(b) $\mathrm{HNO}_{3}(a q)$ or $\mathrm{HNO}_{3}(l)$
(c) $\mathrm{CuSO}_{4}(s)$ or $\mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O}(s)$
20.26 Without consulting Appendix B, arrange each group in order of increasing standard molar entropy $\left(S^{\circ}\right)$. Explain.
(a) Graphite, diamond, charcoal
(b) Ice, water vapor, liquid water
(c) $\mathrm{O}_{2}, \mathrm{O}_{3}, \mathrm{O}$ atoms
20.27 Without consulting Appendix B, arrange each group in order of increasing standard molar entropy $\left(S^{\circ}\right)$. Explain.
(a) Glucose $\left(\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}\right)$, sucrose $\left(\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}\right)$, ribose $\left(\mathrm{C}_{5} \mathrm{H}_{10} \mathrm{O}_{5}\right)$
(b) $\mathrm{CaCO}_{3}, \mathrm{Ca}+\mathrm{C}+\frac{3}{2} \mathrm{O}_{2}, \mathrm{CaO}+\mathrm{CO}_{2}$
(c) $\mathrm{SF}_{6}(g), \mathrm{SF}_{4}(g), \mathrm{S}_{2} \mathrm{~F}_{10}(g)$
20.28 Without consulting Appendix B, arrange each group in order of decreasing standard molar entropy $\left(S^{\circ}\right)$. Explain.
(a) $\mathrm{ClO}_{4}^{-}(a q), \mathrm{ClO}_{2}^{-}(a q), \mathrm{ClO}_{3}^{-}(a q)$
(b) $\mathrm{NO}_{2}(g), \mathrm{NO}(g), \mathrm{N}_{2}(g)$
(c) $\mathrm{Fe}_{2} \mathrm{O}_{3}(s), \mathrm{Al}_{2} \mathrm{O}_{3}(s), \mathrm{Fe}_{3} \mathrm{O}_{4}(s)$
20.29 Without consulting Appendix B, arrange each group in order of decreasing standard molar entropy $\left(S^{\circ}\right)$. Explain.
(a) Mg metal, Ca metal, Ba metal
(b) Hexane $\left(\mathrm{C}_{6} \mathrm{H}_{14}\right)$, benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$, cyclohexane $\left(\mathrm{C}_{6} \mathrm{H}_{12}\right)$
(c) $\mathrm{PF}_{2} \mathrm{Cl}_{3}(g), \mathrm{PF}_{5}(g), \mathrm{PF}_{3}(\mathrm{~g})$

## Calculating the Change in Entropy of a Reaction (Sample Problems 20.2 and 20.3)

## - Concept Review Questions

20.30. For the reaction depicted in the molecular scenes, $X$ is red and Y is green.

(a) Write a balanced equation.
(b) Determine the sign of $\Delta S$.
(c) Which species has the highest molar entropy?
20.31 Describe the equilibrium condition in terms of the entropy changes of a system and its surroundings. What does this description mean about the entropy change of the universe?
20.32 For the reaction $\mathrm{H}_{2} \mathrm{O}(g)+\mathrm{Cl}_{2} \mathrm{O}(g) \longrightarrow 2 \mathrm{HClO}(g)$, you know $\Delta S_{\mathrm{rxn}}^{\circ}$ and $S^{\circ}$ of $\mathrm{HClO}(g)$ and of $\mathrm{H}_{2} \mathrm{O}(g)$. Write an expression that can be used to determine $S^{\circ}$ of $\mathrm{Cl}_{2} \mathrm{O}(g)$.

## - Skill-Building Exercises (grouped in similar pairs)

20.33 For each reaction, predict the sign and find the value of $\Delta S^{\circ}$ :
(a) $3 \mathrm{NO}(g) \longrightarrow \mathrm{N}_{2} \mathrm{O}(g)+\mathrm{NO}_{2}(g)$
(b) $3 \mathrm{H}_{2}(g)+\mathrm{Fe}_{2} \mathrm{O}_{3}(s) \longrightarrow 2 \mathrm{Fe}(s)+3 \mathrm{H}_{2} \mathrm{O}(g)$
(c) $\mathrm{P}_{4}(s)+5 \mathrm{O}_{2}(g) \longrightarrow \mathrm{P}_{4} \mathrm{O}_{10}(s)$
20.34 For each reaction, predict the sign and find the value of $\Delta S^{\circ}$ :
(a) $3 \mathrm{NO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{HNO}_{3}(l)+\mathrm{NO}(g)$
(b) $\mathrm{N}_{2}(g)+3 \mathrm{~F}_{2}(g) \longrightarrow 2 \mathrm{NF}_{3}(g)$
(c) $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(g) \longrightarrow 6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)$
20.35 Find $\Delta S^{\circ}$ for the combustion of ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ to carbon dioxide and gaseous water. Is the sign of $\Delta S^{\circ}$ as expected?
E28.36 Eind $A S^{\circ}$ aor the combustion of methane to carbon dioxide and liquid water. Is the sign of $\Delta S^{\circ}$ as expected?
20.37 Find $\Delta S^{\circ}$ for the reaction of nitrogen monoxide with hydrogen to form ammonia and water vapor. Is the sign of $\Delta S^{\circ}$ as expected?
20.38 Find $\Delta S^{\circ}$ for the combustion of ammonia to nitrogen dioxide and water vapor. Is the sign of $\Delta S^{\circ}$ as expected?
20.39 Find $\Delta S^{\circ}$ for the formation of $\mathrm{Cu}_{2} \mathrm{O}(s)$ from its elements.
20.40 Find $\Delta S^{\circ}$ for the formation of $\mathrm{HI}(g)$ from its elements.
20.41 Find $\Delta S^{\circ}$ for the formation of $\mathrm{CH}_{3} \mathrm{OH}(l)$ from its elements.
20.42 Find $\Delta S^{\circ}$ for the formation of $\mathrm{PCl}_{5}(g)$ from its elements.

## Problems in Context

20.43 Sulfur dioxide is released in the combustion of coal. Scrubbers use aqueous slurries of calcium hydroxide to remove the $\mathrm{SO}_{2}$ from flue gases. Write a balanced equation for this reaction and calculate $\Delta S^{\circ}$ at $298 \mathrm{~K}\left[S^{\circ}\right.$ of $\left.\mathrm{CaSO}_{3}(s)=101.4 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{K}\right]$.
20.44 Oxyacetylene welding is used to repair metal structures, including bridges, buildings, and even the Statue of Liberty. Calculate $\Delta S^{\circ}$ for the combustion of 1 mol of acetylene $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$.

## Entropy, Free Energy, and Work

(Sample Problems 20.4 to 20.7)

## - Concept Review Questions

20.45 What is the advantage of calculating free energy changes rather than entropy changes to determine reaction spontaneity?
20.46 Given that $\Delta G_{\text {sys }}=-T \Delta S_{\text {univ }}$, explain how the sign of $\Delta G_{\text {sys }}$ correlates with reaction spontaneity.
20.47 (a) Is an endothermic reaction more likely to be spontaneous at higher temperatures or lower temperatures? Explain.
(b) The change depicted below occurs at constant pressure. Explain your answers to each of the following: (1) What is the sign of $\Delta H$ ? (2) What is the sign of $\Delta S$ ? (3) What is the sign of $\Delta S_{\text {surr }}$ ? (4) How does the sign of $\Delta G$ vary with temperature?

20.48 With its components in their standard states, a certain reaction is spontaneous only at high $T$. What do you know about the signs of $\Delta H^{\circ}$ and $\Delta S^{\circ}$ ? Describe a process for which this is true. 20.49 How can $\Delta S^{\circ}$ be relatively independent of $T$ if $S^{\circ}$ of each reactant and product increases with $T$ ?

- Skill-Building Exercises (grouped in similar pairs)
20.50 Calculate $\Delta G^{\circ}$ for each reaction using $\Delta G_{\mathrm{f}}^{\circ}$ values:
(a) $2 \mathrm{Mg}(s)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{MgO}(s)$
(b) $2 \mathrm{CH}_{3} \mathrm{OH}(\mathrm{g})+3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{CO}_{2}(\mathrm{~g})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{g})$
(c) $\mathrm{BaO}(s)+\mathrm{CO}_{2}(g) \longrightarrow \mathrm{BaCO}_{3}(s)$
20.51 Calculate $\Delta G^{\circ}$ for each reaction using $\Delta G_{\mathrm{f}}^{\circ}$ values:
(a) $\mathrm{H}_{2}(g)+\mathrm{I}_{2}(s) \longrightarrow 2 \mathrm{HI}(g)$
(b) $\mathrm{MnO}_{2}(s)+2 \mathrm{CO}(g) \longrightarrow \mathrm{Mn}(s)+2 \mathrm{CO}_{2}(g)$
(c) $\mathrm{NH}_{4} \mathrm{Cl}(s) \longrightarrow \mathrm{NH}_{3}(g)+\mathrm{HCl}(g)$
20.52 Find $\Delta G^{\circ}$ for the reactions in Problem 20.50 using $\Delta H_{\mathrm{f}}^{\circ}$ and $S^{\circ}$ values.
20.53 Find $\Delta G^{\circ}$ for the reactions in Problem 20.54 using $\Delta H_{\mathrm{f}}^{\circ}$ and $\mathrm{P}^{2}$ $S^{\circ}$ values.
20.54 Consider the oxidation of carbon monoxide:

$$
\mathrm{CO}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)
$$

(a) Predict the signs of $\Delta S^{\circ}$ and $\Delta H^{\circ}$. Explain.
(b) Calculate $\Delta G^{\circ}$ by two different methods.
20.55 Consider the combustion of butane gas:

$$
\mathrm{C}_{4} \mathrm{H}_{10}(g)+\frac{13}{2} \mathrm{O}_{2}(g) \longrightarrow 4 \mathrm{CO}_{2}(g)+5 \mathrm{H}_{2} \mathrm{O}(g)
$$

(a) Predict the signs of $\Delta S^{\circ}$ and $\Delta H^{\circ}$. Explain.
(b) Calculate $\Delta G^{\circ}$ by two different methods.
20.56 For the gaseous reaction of xenon and fluorine to form xenon hexafluoride:
(a) Calculate $\Delta S^{\circ}$ at $298 \mathrm{~K}\left(\Delta H^{\circ}=-402 \mathrm{~kJ} / \mathrm{mol}\right.$ and $\Delta G^{\circ}=$ $-280 . \mathrm{kJ} / \mathrm{mol}$ ).
(b) Assuming that $\Delta S^{\circ}$ and $\Delta H^{\circ}$ change little with temperature, calculate $\Delta G^{\circ}$ at 500 . K.
20.57 For the gaseous reaction of carbon monoxide and chlorine to form phosgene $\left(\mathrm{COCl}_{2}\right)$ :
(a) Calculate $\Delta S^{\circ}$ at $298 \mathrm{~K}\left(\Delta H^{\circ}=-220 . \mathrm{kJ} / \mathrm{mol}\right.$ and $\Delta G^{\circ}=$ $-206 \mathrm{~kJ} / \mathrm{mol}$ ).
(b) Assuming that $\Delta S^{\circ}$ and $\Delta H^{\circ}$ change little with temperature, calculate $\Delta G^{\circ}$ at 450 . K.
20.58 One reaction used to produce small quantities of pure $\mathrm{H}_{2}$ is

$$
\mathrm{CH}_{3} \mathrm{OH}(g) \rightleftharpoons \mathrm{CO}(g)+2 \mathrm{H}_{2}(g)
$$

(a) Determine $\Delta H^{\circ}$ and $\Delta S^{\circ}$ for the reaction at 298 K .
(b) Assuming that these values are relatively independent of temperature, calculate $\Delta G^{\circ}$ at $28^{\circ} \mathrm{C}, 128^{\circ} \mathrm{C}$, and $228^{\circ} \mathrm{C}$.
(c) What is the significance of the different values of $\Delta G^{\circ}$ ?
20.59 A reaction that occurs in the internal combustion engine is

$$
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{NO}(g)
$$

(a) Determine $\Delta H^{\circ}$ and $\Delta S^{\circ}$ for the reaction at 298 K .
(b) Assuming that these values are relatively independent of temperature, calculate $\Delta G^{\circ}$ at $100 .{ }^{\circ} \mathrm{C}, 2560 .{ }^{\circ} \mathrm{C}$, and $3540 .{ }^{\circ} \mathrm{C}$.
(c) What is the significance of the different values of $\Delta G^{\circ}$ ?
20.60 Use $\Delta H^{\circ}$ and $\Delta S^{\circ}$ values for the following process at 1 atm to find the normal boiling point of $\mathrm{Br}_{2}$ :

$$
\mathrm{Br}_{2}(l) \rightleftharpoons \mathrm{Br}_{2}(g)
$$

20.61 Use $\Delta H^{\circ}$ and $\Delta S^{\circ}$ values to find the temperature at which these sulfur allotropes reach equilibrium at 1 atm :

$$
\mathrm{S}(\text { rhombic }) \rightleftharpoons \mathrm{S}(\text { monoclinic })
$$

## Problems in Context

20.62 As a fuel, $\mathrm{H}_{2}(g)$ produces only nonpolluting $\mathrm{H}_{2} \mathrm{O}(g)$ when it burns. Moreover, it combines with $\mathrm{O}_{2}(g)$ in a fuel cell (Chapter 21) to provide electrical energy.
(a) Calculate $\Delta H^{\circ}, \Delta S^{\circ}$, and $\Delta G^{\circ}$ per mole of $\mathrm{H}_{2}$ at 298 K .
(b) Is the spontaneity of this reaction dependent on $T$ ? Explain.
(c) At what temperature does the reaction become spontaneous?
20.63 The U.S. government requires automobile fuels to contain a renewable component. Fermentation of glucose from corn yields ethanol, which is added to gasoline to fulfill this requirement:

$$
\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s) \longrightarrow 2 \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)+2 \mathrm{CO}_{2}(g)
$$

Calculate $\Delta H^{\circ}, \Delta S^{\circ}$, and $\Delta G^{\circ}$ for the reaction at $25^{\circ} \mathrm{C}$. Is the spontaneity of this reaction dependent on $T$ ? Explain.

Free Energy, Equilibrium, and Reaction Direction
(Sample Problems 20.8 and 20.9)
Concept Review Questions
20.64 (a) If $K \ll 1$ for a reaction, what do you know about the sign and magnitude of $\Delta G^{\circ}$ ? (b) If $\Delta G^{\circ} \ll 0$ for a reaction, what do you know about the magnitude of $K$ ? Of $Q$ ?
20.65 How is the free energy change of a process related to the work that can be obtained from the process? Is this quantity of work obtainable in practice? Explain.
20.66 The scenes and the graph relate to the reaction of $\mathrm{X}_{2}(g)$ (black) with $\mathrm{Y}_{2}(g)$ (orange) to form $\mathrm{XY}(g)$. (a) If reactants and products are in their standard states, what quantity is represented on the graph by $x$ ? (b) Which scene represents point 1 ? Explain. (c) Which scene represents point 2? Explain.

20.67 What is the difference between $\Delta G^{\circ}$ and $\Delta G$ ? Under what circumstances does $\Delta G=\Delta G^{\circ}$ ?

## - Skill-Building Exercises (grouped in similar pairs)

20.68 Calculate $K$ at 298 K for each reaction:
(a) $\mathrm{NO}(g)+\frac{1}{2} \mathrm{O}_{2}(g) \rightleftharpoons \mathrm{NO}_{2}(g)$
(b) $2 \mathrm{HCl}(g) \rightleftharpoons \mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g)$
(c) 2 C (graphite) $+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{CO}(g)$
20.69 Calculate $K$ at 298 K for each reaction:
(a) $\mathrm{MgCO}_{3}(s) \rightleftharpoons \mathrm{Mg}^{2+}(a q)+\mathrm{CO}_{3}{ }^{2-}(a q)$
(b) $2 \mathrm{HCl}(g)+\mathrm{Br}_{2}(l) \rightleftharpoons 2 \mathrm{HBr}(g)+\mathrm{Cl}_{2}(g)$
(c) $\mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \rightleftharpoons \mathrm{H}_{2} \mathrm{O}_{2}(l)$
20.70 Calculate $K$ at 298 K for each reaction:
(a) $2 \mathrm{H}_{2} \mathrm{~S}(g)+3 \mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{H}_{2} \mathrm{O}(g)+2 \mathrm{SO}_{2}(g)$
(b) $\mathrm{H}_{2} \mathrm{SO}_{4}(l) \rightleftharpoons \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{SO}_{3}(g)$
(c) $\mathrm{HCN}(a q)+\mathrm{NaOH}(a q) \rightleftharpoons \mathrm{NaCN}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$
20.71 Calculate $K$ at 298 K for each reaction:
(a) $\mathrm{SrSO}_{4}(s) \rightleftharpoons \mathrm{Sr}^{2+}(a q)+\mathrm{SO}_{4}{ }^{2-}(a q)$
(b) $2 \mathrm{NO}(g)+\mathrm{Cl}_{2}(g) \rightleftharpoons 2 \mathrm{NOCl}(g)$
(c) $\mathrm{Cu}_{2} \mathrm{~S}(\mathrm{~s})+\mathrm{O}_{2}(g) \rightleftharpoons 2 \mathrm{Cu}(s)+\mathrm{SO}_{2}(g)$
20.72 Use Appendix B to determine the $K_{\text {sp }}$ of $\mathrm{Ag}_{2} \mathrm{~S}$.
20.73 Use Appendix B to determine the $K_{\text {sp }}$ of $\mathrm{CaF}_{2}$.
20.74 For the reaction $\mathrm{I}_{2}(g)+\mathrm{Cl}_{2}(g) \rightleftharpoons 2 \mathrm{ICl}(g)$, calculate $K_{\mathrm{p}}$ at $25^{\circ} \mathrm{C}\left[\Delta G_{\mathrm{f}}^{\circ}\right.$ of $\left.\mathrm{ICl}(\mathrm{g})=-6.075 \mathrm{~kJ} / \mathrm{mol}\right]$.
20.75 For the reaction $\mathrm{CaCO}_{3}(s) \rightleftharpoons \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)$, calculate the equilibrium $P_{\mathrm{CO}_{2}}$ at $25^{\circ} \mathrm{C}$.
20.76 The $K_{\text {sp }}$ of $\mathrm{PbCl}_{2}$ is $1.7 \times 10^{-5}$ at $25^{\circ} \mathrm{C}$. What is $\Delta G^{\circ}$ ? Is it possible to prepare a solution that contains $\mathrm{Pb}^{2+}(a q)$ and $\mathrm{Cl}^{-}(a q)$, at their standard-state concentrations?
20.77 The $K_{\text {sp }}$ of $\mathrm{ZnF}_{2}$ is $3.0 \times 10^{-2}$ at $25^{\circ} \mathrm{C}$. What is $\Delta G^{\circ}$ ? Is it possible to prepare a solution that contains $\mathrm{Zn}^{2+}(a q)$ and $\mathrm{F}^{-}(a q)$ at their standard-state concentrations?
20.78 The equilibrium constant for the reaction $\left.2 \mathrm{Fe}^{3+}(a q)+\mathrm{Hg}_{2}{ }^{2+}(a q) \rightleftharpoons 2 \mathrm{Fe}^{2} \mathrm{Aq}\right)\left(\mathbb{2} \mathrm{Hg}^{2+} \mathrm{Raq}\right) \mathrm{F}$ is $K_{\mathrm{c}}=9.1 \times 10^{-6}$ at 298 K .
(a) What is $\Delta G^{\circ}$ at this temperature?
(b) If standard-state concentrations of the reactants and products are mixed, in which direction does the reaction proceed?
(c) Calculate $\Delta G$ when $\left[\mathrm{Fe}^{3+}\right]=0.20 \mathrm{M},\left[\mathrm{Hg}_{2}{ }^{2+}\right]=0.010 \mathrm{M}$, $\left[\mathrm{Fe}^{2+}\right]=0.010 M$, and $\left[\mathrm{Hg}^{2+}\right]=0.025 M$. In which direction will the reaction proceed to achieve equilibrium?
20.79 The formation constant for the reaction

$$
\mathrm{Ni}^{2+}(a q)+6 \mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}(a q)
$$

is $K_{\mathrm{f}}=5.6 \times 10^{8}$ at $25^{\circ} \mathrm{C}$.
(a) What is $\Delta G^{\circ}$ at this temperature?
(b) If standard-state concentrations of the reactants and products are mixed, in which direction does the reaction proceed?
(c) Determine $\Delta G$ when $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}\right]=0.010 M,\left[\mathrm{Ni}^{2+}\right]=$ 0.0010 M , and $\left[\mathrm{NH}_{3}\right]=0.0050 \mathrm{M}$. In which direction will the reaction proceed to achieve equilibrium?

## - Problems in Context

20.80 High levels of ozone $\left(\mathrm{O}_{3}\right)$ cause rubber to deteriorate, green plants to turn brown, and many people to have difficulty breathing. (a) Is the formation of $\mathrm{O}_{3}$ from $\mathrm{O}_{2}$ favored at all $T$, no $T$, high $T$, or low $T$ ?
(b) Calculate $\Delta G^{\circ}$ for this reaction at 298 K .
(c) Calculate $\Delta G$ at 298 K for this reaction in urban smog where
$\left[\mathrm{O}_{2}\right]=0.21 \mathrm{~atm}$ and $\left[\mathrm{O}_{3}\right]=5 \times 10^{-7} \mathrm{~atm}$.
$20.81 \mathrm{~A} \mathrm{BaSO}_{4}$ slurry is ingested before the gastrointestinal tract is x-rayed because it is opaque to x-rays and defines the contours of the tract. $\mathrm{Ba}^{2+}$ ion is toxic, but the compound is nearly insoluble. If $\Delta G^{\circ}$ at $37^{\circ} \mathrm{C}$ (body temperature) is $59.1 \mathrm{~kJ} / \mathrm{mol}$ for the process

$$
\mathrm{BaSO}_{4}(s) \rightleftharpoons \mathrm{Ba}^{2+}(a q)+\mathrm{SO}_{4}^{2-}(a q)
$$

what is $\left[\mathrm{Ba}^{2+}\right]$ in the intestinal tract? (Assume that the only source of $\mathrm{SO}_{4}{ }^{2--}$ is the ingested slurry.)

## Comprehensive Problems

20.82 According to advertisements, "a diamond is forever."
(a) Calculate $\Delta H^{\circ}, \Delta S^{\circ}$, and $\Delta G^{\circ}$ at 298 K for the phase change Diamond $\longrightarrow$ graphite
(b) Given the conditions under which diamond jewelry is normally kept, argue for and against the statement in the ad.
(c) Given the answers in part (a), what would need to be done to make synthetic diamonds from graphite?
(d) Assuming $\Delta H^{\circ}$ and $\Delta S^{\circ}$ do not change with temperature, can graphite be converted to diamond spontaneously at 1 atm ?
20.83 Replace each question mark with the correct information:

|  | $\Delta \boldsymbol{S}_{\mathrm{rxn}}$ | $\Delta \boldsymbol{H}_{\mathrm{rxn}}$ | $\boldsymbol{\Delta} \boldsymbol{G}_{\mathrm{rxn}}$ | Comment |
| :--- | :---: | :---: | :---: | :--- |
| (a) | + | - | - | $?$ |
| (b) | $?$ | 0 | - | Spontaneous |
| (c) | - | + | $?$ | Not spontaneous |
| (d) | 0 | $?$ | - | Spontaneous |
| (e) | $?$ | 0 | + | $?$ |
| (f) | + | + | $?$ | $T \Delta S>\Delta H$ |

20.84 Among the many complex ions of cobalt are the following: $\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+}(a q)+3 \mathrm{en}(a q) \rightleftharpoons \mathrm{Co}(\mathrm{en})_{3}{ }^{3+}(a q)+6 \mathrm{NH}_{3}(a q)$ where "en" stands for ethylenediamine, $\mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}$. Six $\mathrm{Co}-\mathrm{N}$ bonds are broken and six $\mathrm{Co}-\mathrm{N}$ bonds are formed in this reaction, so $\Delta H_{\mathrm{rxn}}^{\circ} \approx 0$; yet $K>1$. What are the signs of $\Delta S^{\circ}$ and $\Delta G^{\circ}$ ? What drives the reaction?
20.85 What frethange in entropy when 0.200 mol of potassium freezes at $63.7^{\circ} \mathrm{C}\left(\Delta H_{\text {fus }}=2.39 \mathrm{~kJ} / \mathrm{mol}\right)$ ?
20.86 Is each statement true or false? If false, correct it.
(a) All spontaneous reactions occur quickly.
(b) The reverse of a spontaneous reaction is nonspontaneous.
(c) All spontaneous processes release heat.
(d) The boiling of water at $100^{\circ} \mathrm{C}$ and 1 atm is spontaneous.
(e) If a process increases the freedom of motion of the particles of a system, the entropy of the system decreases.
(f) The energy of the universe is constant; the entropy of the universe decreases toward a minimum.
(g) All systems disperse their energy spontaneously.
(h) Both $\Delta S_{\text {sys }}$ and $\Delta S_{\text {surr }}$ equal zero at equilibrium.
20.87 Hemoglobin carries $\mathrm{O}_{2}$ from the lungs to tissue cells, where the $\mathrm{O}_{2}$ is released. The protein is represented as Hb in its unoxygenated form and as $\mathrm{Hb} \cdot \mathrm{O}_{2}$ in its oxygenated form. One reason CO is toxic is that it competes with $\mathrm{O}_{2}$ in binding to Hb :

$$
\mathrm{Hb} \cdot \mathrm{O}_{2}(a q)+\mathrm{CO}(g) \rightleftharpoons \mathrm{Hb} \cdot \mathrm{CO}(a q)+\mathrm{O}_{2}(g)
$$

(a) If $\Delta G^{\circ} \approx-14 \mathrm{~kJ}$ at $37^{\circ} \mathrm{C}$ (body temperature), what is the ratio of $[\mathrm{Hb} \cdot \mathrm{CO}]$ to $\left[\mathrm{Hb} \cdot \mathrm{O}_{2}\right]$ at $37^{\circ} \mathrm{C}$ with $\left[\mathrm{O}_{2}\right]=[\mathrm{CO}]$ ?
(b) How is Le Châtelier's principle used to treat CO poisoning?
20.88 An important ore of lithium is spodumene, $\mathrm{LiAlSi}_{2} \mathrm{O}_{6}$. To extract the metal, the $\alpha$ form of spodumene is first converted into the less dense $\beta$ form in preparation for subsequent leaching and washing steps. Use the following data to calculate the lowest temperature at which the $\alpha \longrightarrow \beta$ conversion is feasible:

|  | $\Delta H_{\mathrm{f}}^{\circ}(\mathrm{kJ} / \mathrm{mol})$ | $\boldsymbol{S}^{\circ}(\mathrm{J} / \mathrm{mol} \cdot \mathrm{K})$ |
| :--- | :---: | :---: |
| $\alpha$-spodumene | -3055 | 129.3 |
| $\beta$-spodumene | -3027 | 154.4 |

20.89 Magnesia ( MgO ) is used for fire brick, crucibles, and furnace linings because of its high melting point. It is produced by decomposing magnesite $\left(\mathrm{MgCO}_{3}\right)$ at around $1200^{\circ} \mathrm{C}$.
(a) Write a balanced equation for magnesite decomposition.
(b) Use $\Delta H^{\circ}$ and $S^{\circ}$ values to find $\Delta G^{\circ}$ at 298 K .
(c) Assuming $\Delta H^{\circ}$ and $S^{\circ}$ do not change with temperature, find the minimum temperature at which the reaction is spontaneous.
(d) Calculate the equilibrium $P_{\mathrm{CO}_{2}}$ above $\mathrm{MgCO}_{3}$ at 298 K .
(e) Calculate the equilibrium $P_{\mathrm{CO}_{2}}$ above $\mathrm{MgCO}_{3}$ at 1200 K .
20.90 To prepare nuclear fuel, $\mathrm{U}_{3} \mathrm{O}_{8}$ ("yellow cake") is converted to $\mathrm{UO}_{2}\left(\mathrm{NO}_{3}\right)_{2}$, which is then converted to $\mathrm{UO}_{3}$ and finally $\mathrm{UO}_{2}$. The fuel is enriched (the proportion of the ${ }^{235} \mathrm{U}$ is increased) by a two-step conversion of $\mathrm{UO}_{2}$ into $\mathrm{UF}_{6}$, a volatile solid, followed by a gaseous-diffusion separation of the ${ }^{235} \mathrm{U}$ and ${ }^{238} \mathrm{U}$ isotopes:

$$
\begin{aligned}
\mathrm{UO}_{2}(s)+4 \mathrm{HF}(g) & \longrightarrow \mathrm{UF}_{4}(s)+2 \mathrm{H}_{2} \mathrm{O}(g) \\
\mathrm{UF}_{4}(s)+\mathrm{F}_{2}(g) & \longrightarrow \mathrm{UF}_{6}(s)
\end{aligned}
$$

Calculate $\Delta G^{\circ}$ for the overall process at $85^{\circ} \mathrm{C}$ :

|  | $\boldsymbol{\Delta} \boldsymbol{H}_{\mathrm{f}}^{\circ}(\mathrm{kJ} / \mathrm{mol})$ | $\boldsymbol{S}^{\circ}(\mathrm{J} / \mathrm{mol} \cdot \mathrm{K})$ | $\boldsymbol{\Delta} \boldsymbol{G}_{\mathrm{f}}^{\circ}(\mathrm{kJ} / \mathrm{mol})$ |
| :--- | :---: | :---: | :---: |
| $\mathrm{UO}_{2}(s)$ | -1085 | 77.0 | -1032 |
| $\mathrm{UF}_{4}(s)$ | -1921 | 152 | -1830. |
| $\mathrm{UF}_{6}(s)$ | -2197 | 225 | -2068 |

20.91 Methanol, a major industrial feedstock, is made by several catalyzed reactions, such as $\mathrm{CO}(g)+2 \mathrm{H}_{2}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{OH}(l)$.
(a) Show that this reaction is thermodynamically feasible.
(b) Is it favored at low or at high temperatures?
(c) One concern about using $\mathrm{CH}_{3} \mathrm{OH}$ as an auto fuel is its oxidation in air to yield formaldehyde, $\mathrm{CH}_{2} \mathrm{O}(\mathrm{g})$, which poses a health hazard. Calculate $\Delta G^{\circ}$ at $100 .{ }^{\circ} \mathrm{C}$ for this oxidfona go PD
20.92 (a) Write a balanced equation for the gaseous reaction between $\mathrm{N}_{2} \mathrm{O}_{5}$ and $\mathrm{F}_{2}$ to form $\mathrm{NF}_{3}$ and $\mathrm{O}_{2}$. (b) Determine $\Delta G_{\mathrm{rxn}}^{\circ}$. (c) Find $\Delta G_{\mathrm{rxn}}$ at 298 K if $P_{\mathrm{N}_{2} \mathrm{O}_{5}}=P_{\mathrm{F}_{2}}=0.20 \mathrm{~atm}, P_{\mathrm{NF}_{3}}=$ 0.25 atm , and $P_{\mathrm{O}_{2}}=0.50 \mathrm{~atm}$.
20.93 Consider the following reaction:

$$
2 \mathrm{NOBr}(g) \rightleftharpoons 2 \mathrm{NO}(g)+\mathrm{Br}_{2}(g) \quad K=0.42 \text { at } 373 \mathrm{~K}
$$

Given that $S^{\circ}$ of $\operatorname{NOBr}(g)=272.6 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{K}$ and that $\Delta S_{\mathrm{rxn}}^{\circ}$ and $\Delta H_{\mathrm{rxn}}^{\circ}$ are constant with temperature, find
(a) $\Delta S_{\mathrm{rxn}}^{\circ}$ at 298 K
(b) $\Delta G_{\mathrm{rxn}}^{\circ}$ at 373 K
(c) $\Delta H_{\mathrm{rxn}}^{\circ}$ at 373 K
(d) $\Delta H_{\mathrm{f}}^{\circ}$ of NOBr at 298 K
(e) $\Delta G_{\text {rxn }}^{\circ}$ at 298 K
(f) $\Delta G_{\mathrm{f}}^{\circ}$ of NOBr at 298 K
20.94 Calculate the equilibrium constants for decomposition of the hydrogen halides at 298 K :

$$
2 \mathrm{HX}(g) \rightleftharpoons \mathrm{H}_{2}(g)+\mathrm{X}_{2}(g)
$$

What do these values indicate about the extent of decomposition of HX at 298 K? Suggest a reason for this trend.
20.95 Hydrogenation is the addition of $\mathrm{H}_{2}$ to double (or triple) carbon-carbon bonds. Peanut butter and most commercial baked goods include hydrogenated oils. Find $\Delta H^{\circ}, \Delta S^{\circ}$, and $\Delta G^{\circ}$ for the hydrogenation of ethene $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$ to ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ at $25^{\circ} \mathrm{C}$.
20.96 Styrene is produced by catalytic dehydrogenation of ethylbenzene at high temperature in the presence of superheated steam. (a) Find $\Delta H_{\mathrm{rxn}}^{\circ}, \Delta G_{\mathrm{rxn}}^{\circ}$, and $\Delta S_{\mathrm{rxn}}^{\circ}$, given these data at 298 K :

| Compound | $\Delta H_{f}^{\circ}$ <br> $(\mathrm{kJ} / \mathrm{mol})$ | $\Delta G_{f}^{\circ}$ <br> $(\mathrm{kJ} / \mathrm{mol})$ | $S^{\circ}$ <br> $(\mathrm{J} / \mathrm{mol} \cdot \mathrm{K})$ |
| :--- | :---: | :---: | :---: |
| Ethylbenzene, $\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{CH}_{2} \mathrm{CH}_{3}$ | -12.5 | 119.7 | 255 |
| Styrene, $\mathrm{C}_{6} \mathrm{H}_{5}-\mathrm{CH}=\mathrm{CH}_{2}$ | 103.8 | 202.5 | 238 |

(b) At what temperature is the reaction spontaneous?
(c) What are $\Delta G_{\mathrm{rxn}}^{\circ}$ and $K$ at $600 .{ }^{\circ} \mathrm{C}$ ?
(d) With 5.0 parts steam to 1.0 part ethylbenzene in the reactant mixture and the total pressure kept constant at 1.3 atm , what is $\Delta G$ at $50 . \%$ conversion, that is, when $50 . \%$ of the ethylbenzene has reacted?
20.97 Bromine monochloride is formed from the elements:

$$
\begin{gathered}
\quad \mathrm{Cl}_{2}(g)+\mathrm{Br}_{2}(g) \longrightarrow 2 \mathrm{BrCl}(g) \\
\Delta H_{\mathrm{rxn}}^{\circ}=-1.35 \mathrm{~kJ} / \mathrm{mol} \quad \Delta G_{\mathrm{f}}^{\circ}=-0.88 \mathrm{~kJ} / \mathrm{mol} \\
\text { Calculate (a) } \Delta H_{\mathrm{f}}^{\circ} \text { and (b) } S^{\circ} \text { of } \mathrm{BrCl}(g) .
\end{gathered}
$$

20.98 Propylene (propene; $\mathrm{CH}_{3} \mathrm{CH}=\mathrm{CH}_{2}$ ) is used to produce polypropylene and many other chemicals. Although most is obtained from the cracking of petroleum, about $2 \%$ is produced by catalytic dehydrogenation of propane $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}\right)$ :

Because this reaction is endothermic, heaters are placed between the reactor vessels to maintain the required temperature.
(a) If the molar entropy, $S^{\circ}$, of propylene is $267.1 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{K}$, find its entropy of formation, $S_{\mathrm{f}}^{\circ}$.
(b) Find $\Delta G_{\mathrm{f}}^{\circ}$ of propylene ( $\Delta H_{\mathrm{f}}^{\circ}$ for propylene $=20.4 \mathrm{~kJ} / \mathrm{mol}$ ).
(c) Calculate $\Delta H_{\mathrm{rxn}}^{\circ}$ and $\Delta G_{\mathrm{rxn}}^{\circ}$ for the dehydrogenation.
(d) What is the theoretical yield of propylene at $580^{\circ} \mathrm{C}$ if the initial pressure of propane is 1.00 atm ?
(e) Would the yield change if the reactor walls were permeable to $\mathrm{H}_{2}$ ? Explain.
(f) At what temperature is the dehydrogenation spontaneous, with all substances in the standard state?
Note: Problems 20.99 to 20.102 relate to the thermodynamics Fof adenosine triptospinate (ATP). Refer to the Chemical Connections essay on pp. 908-909.
20.99 Find $K$ for (a) the hydrolysis of ATP, (b) the dehydrationcondensation to form glucose phosphate, and (c) the coupled reaction between ATP and glucose. (d) How does each $K$ change when $T$ changes from $25^{\circ} \mathrm{C}$ to $37^{\circ} \mathrm{C}$ ?
20.100 The oxidation of 1 mol of glucose supplies enough metabolic energy to form 36 mol of ATP. Oxidation of 1 mol of a typical dietary fat like tristearin $\left(\mathrm{C}_{57} \mathrm{H}_{116} \mathrm{O}_{6}\right)$ yields enough energy to form 458 mol of ATP. (a) How many molecules of ATP can form per gram of glucose? (b) Per gram of tristearin?
20.101 Nonspontaneous processes like muscle contraction, protein building, and nerve conduction are coupled to the spontaneous hydrolysis of ATP to ADP. ATP is then regenerated by coupling its synthesis to other energy-yielding reactions such as Creatine phosphate $\longrightarrow$ creatine + phosphate

$$
\Delta G^{\circ \prime}=-43.1 \mathrm{~kJ} / \mathrm{mol}
$$

$$
\text { ADP }+ \text { phosphate } \longrightarrow \text { ATP } \quad \Delta G^{\circ \prime}=+30.5 \mathrm{~kJ} / \mathrm{mol}
$$

Calculate $\Delta G^{\circ}$ for the overall reaction that regenerates ATP.
20.102 Energy from ATP hydrolysis drives many nonspontaneous cell reactions:

$$
\operatorname{ATP}^{4-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons
$$

$\mathrm{ADP}^{3-}(a q)+\mathrm{HPO}_{4}{ }^{2-}(a q)+\mathrm{H}^{+}(a q) \quad \Delta G^{\circ \prime}=-30.5 \mathrm{~kJ}$ Energy for the reverse process comes ultimately from glucose metabolism:

$$
\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(g) \longrightarrow 6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l)
$$

(a) Find $K$ for the hydrolysis of ATP at $37^{\circ} \mathrm{C}$.
(b) Find $\Delta G_{\mathrm{rxn}}^{\circ}$ for metabolism of 1 mol of glucose.
(c) How many moles of ATP can be produced by metabolism of 1 mol of glucose?
(d) If 36 mol of ATP is formed, what is the actual yield?
20.103 From the following reaction and data, find (a) $S^{\circ}$ of $\mathrm{SOCl}_{2}$ and (b) $T$ at which the reaction becomes nonspontaneous:

$$
\mathrm{SO}_{3}(g)+\mathrm{SCl}_{2}(l) \longrightarrow \mathrm{SOCl}_{2}(l)+\mathrm{SO}_{2}(g) \quad \Delta G_{\mathrm{rxn}}^{\circ}=-75.2 \mathrm{~kJ}
$$

|  | $\mathrm{SO}_{3}(g)$ | $\mathrm{SCl}_{2}(l)$ | $\mathrm{SOCl}_{2}(l)$ | $\mathrm{SO}_{2}(g)$ |
| :--- | :---: | :---: | :---: | ---: |
| $\Delta H_{\mathrm{f}}^{\circ}(\mathrm{kJ} / \mathrm{mol})$ | -396 | -50.0 | -245.6 | -296.8 |
| $S^{\circ}(\mathrm{J} / \mathrm{mol} \cdot \mathrm{K})$ | 256.7 | 184 | - | 248.1 |

20.104 Write equations for the oxidation of Fe and of Al . Use $\Delta G_{\mathrm{f}}^{\circ}$ to determine whether either process is spontaneous at $25^{\circ} \mathrm{C}$.
20.105. The molecular scene depicts a gaseous equilibrium mixture at $460^{\circ} \mathrm{C}$ for the reaction of $\mathrm{H}_{2}$ (blue) and $\mathrm{I}_{2}$ (purple) to form HI. Each molecule represents 0.010 mol and the container volume is 1.0 L . (a) Is $K_{\mathrm{c}}>,=$, or $<1$ ? (b) Is $K_{\mathrm{p}}>,=$, or $<K_{\mathrm{c}}$ ? (c) Calculate $\Delta G_{\mathrm{rxn}}^{\circ}$. (d) How would the value of $\Delta G_{\mathrm{rxn}}^{\circ}$ change if the purple molecules
 represented $\mathrm{H}_{2}$ and the blue $\mathrm{I}_{2}$ ? Explain.
20.106 A key step in the metabolism of glucose for energy is the isomerization of glucose-6-phosphate (G6P) to fructose-6phosphate (F6P): G6P $\rightleftharpoons$ F6P; $K=0.510$ at 298 K .
(a) Calculate $\Delta G^{\circ}$ at 298 K .
(b) Calculate $\Delta G$ when $Q$, the $[\mathrm{F} 6 \mathrm{P}] /[\mathrm{G} 6 \mathrm{P}]$ ratio, equals 10.0 .
(c) Calculate $\Delta G$ when $Q=0.100$.
 can reach equilibrium at many temperatures. In contrast, a phase change, such as ice melting, is in equilibrium at a given pressure only at the melting point. Each of the graphs below depicts $G_{\text {sys }}$ vs. extent of change. (a) Which graph depicts how $G_{\text {sys }}$ changes for the formation of HI? Explain. (b) Which graph depicts how $G_{\text {sys }}$ changes as ice melts at $1^{\circ} \mathrm{C}$ and 1 atm ? Explain.

A

B

C

D
20.108 When heated, the DNA double helix separates into two random-coil single strands. When cooled, the random coils reform the double helix: double helix $\rightleftharpoons 2$ random coils.
(a) What is the sign of $\Delta S$ for the forward process? Why?
(b) Energy must be added to overcome H bonds and dispersion forces between the strands. What is the sign of $\Delta G$ for the forward process when $T \Delta S$ is smaller than $\Delta H$ ?
(c) Write an expression that shows $T$ in terms of $\Delta H$ and $\Delta S$ when the reaction is at equilibrium. (This temperature is called the melting temperature of the nucleic acid.)
20.109 In the process of respiration, glucose is oxidized completely. In fermentation, $\mathrm{O}_{2}$ is absent and glucose is broken down to ethanol and $\mathrm{CO}_{2}$. Ethanol is oxidized to $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$.
(a) Balance the following equations for these processes:

Respiration: $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)$
Fermentation: $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s) \longrightarrow \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)+\mathrm{CO}_{2}(g)$
Ethanol oxidation: $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)$
(b) Calculate $\Delta G_{\mathrm{rxn}}^{\circ}$ for respiration of 1.00 g of glucose.
(c) Calculate $\Delta G_{\mathrm{rxn}}^{\circ}$ for fermentation of 1.00 g of glucose.
(d) Calculate $\Delta G_{\mathrm{rxn}}^{\circ}$ for oxidation of the ethanol from part (c).
20.110 Consider the formation of ammonia:

$$
\mathrm{N}_{2}(g)+3 \mathrm{H}_{2}(g) \rightleftharpoons 2 \mathrm{NH}_{3}(g)
$$

(a) Assuming that $\Delta H^{\circ}$ and $\Delta S^{\circ}$ are constant with temperature, find the temperature at which $K_{\mathrm{p}}=1.00$.
(b) Find $K_{\mathrm{p}}$ at $400 .{ }^{\circ} \mathrm{C}$, a typical temperature for $\mathrm{NH}_{3}$ production.
(c) Given the lower $K_{\mathrm{p}}$ at the higher temperature, why are these conditions used industrially?
20.111 Kyanite, sillimanite, and andalusite all have the formula $\mathrm{Al}_{2} \mathrm{SiO}_{5}$. Each is stable under different conditions (see the graph at right). At the point where the three phases intersect:
(a) Which mineral, if any, has the lowest free en-
 ergy?
(b) Which mineral, if any, has the lowest enthalpy?
(c) Which mineral, if any, has the highest entropy?
(d) Which mineral, if any, has the lowest density?

F $\mathbf{2 0 . 1 1 2}$ Acetylene is produced commercially by the partial oxidation of methane. At $1500^{\circ} \mathrm{C}$ and pressures of $1-10$ bar, the yield of acetylene is about $20 \%$. The major side product is carbon monoxide, and some soot and carbon dioxide also form.
(a) At what temperature is the desired reaction spontaneous:

$$
2 \mathrm{CH}_{4}+\frac{1}{2} \mathrm{O}_{2} \longrightarrow \mathrm{C}_{2} \mathrm{H}_{2}+2 \mathrm{H}_{2}+\mathrm{H}_{2} \mathrm{O}
$$

(b) Acetylene can also be made by the reaction of its elements, carbon (graphite) and hydrogen. At what temperature is this formation reaction spontaneous? (c) Why must this reaction mixture be immediately cooled?
20.113 Synthesis gas, a mixture that includes the fuels CO and $\mathrm{H}_{2}$, is used to produce liquid hydrocarbons and methanol. It is made at pressures up to 100 atm by oxidation of methane followed by the steam re-forming and water-gas shift reactions. Because the process is exothermic, temperatures reach $950-1100^{\circ} \mathrm{C}$, and the conditions are such that the amounts of $\mathrm{H}_{2}, \mathrm{CO}, \mathrm{CO}_{2}, \mathrm{CH}_{4}$, and $\mathrm{H}_{2} \mathrm{O}$ leaving the reactor are close to the equilibrium amounts for the steam re-forming and water-gas shift reactions:

$$
\begin{aligned}
& \mathrm{CH}_{4}(g)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons \mathrm{CO}(g)+3 \mathrm{H}_{2}(g) \\
& \mathrm{CO}(g)+\mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons \mathrm{CO}_{2}(g)+\mathrm{H}_{2}(g) \text { (steam re-forming) } \\
& \text { (water-gas shift) }
\end{aligned}
$$

(a) At $1000 .{ }^{\circ} \mathrm{C}$, what are $\Delta G^{\circ}$ and $\Delta H^{\circ}$ for the steam re-forming reaction and for the water-gas shift reaction?
(b) By doubling the steam re-forming step and adding it to the water-gas shift step, we obtain the following combined reaction:

$$
2 \mathrm{CH}_{4}(g)+3 \mathrm{H}_{2} \mathrm{O}(g) \rightleftharpoons \mathrm{CO}_{2}(g)+\mathrm{CO}(g)+7 \mathrm{H}_{2}(g)
$$

Is this reaction spontaneous at $1000 .{ }^{\circ} \mathrm{C}$ in the standard state?
(c) Is it spontaneous at 98 atm and $50 . \%$ conversion (when 50.\% of the starting materials have reacted)?
(d) Is it spontaneous at 98 atm and $90 . \%$ conversion?

Electrochemical Cells for Every Occasion Perhaps near you right now are a laptop, an MP3 player, and a cell phone--just a few of the devices whose energy comes from an electrochemical cell. In this chapter, you'll look at the two faces of electrochemistry-reactions in cells, such as those in batteries, that do electrical work and reactions in cells that require electrical work to occur. Both are indispensable to our modern way of life.

Thermodynamics has many applications other than expanding gases inside steam engines. In fact, some applications are probably within your reach right now, in the form of battery-operated devices-laptop computer, palm organizer, DVD remote, and, of course, wristwatch and calculator-or in the form of metal-plated jewelry or silverware. The operation and creation of these objects, and the many similar ones you use daily, involve the principles of electrochemistry, one of the most important areas of applied thermodynamics.

Electrochemistry is the study of the relationship between chemical change and electrical work. It is typically investigated through the use of electrochemical cells, systems that incorporate a redox reaction to produce or utilize electrical energy. The common objects just mentioned highlight the essential difference between the two types of electrochemical cells:

- One type of cell does work by releasing free energy from a spontaneous reaction to produce electricity. A battery houses this type of cell.
- The other type of cell does work by absorbing free energy from a source of electricity to drive a nonspontaneous reaction. Such cells are used to plate a thin layer of metal on objects and, in major industrial processes, produce some compounds and nonmetals and recover many metals from their ores.

IN THIS CHAPTER . . . We review redox concepts and highlight a method for balancing redox equations (mentioned briefly in Chapter 4) that is particularly useful for electrochemical cells. An overview of the two cell types follows. The first type releases free energy to do electrical work, and we see how and why it operates. The cell's electrical output and its relation to the relative strengths of the redox species concern us next. We then examine the free energy change and equilibrium nature of the cell reaction and how they relate to the cell output. The concentration cells and batteries we consider are useful examples of this type of cell, and corrosion is a destructive electrochemical process that operates by the same principle. Next, we focus on cells that absorb free energy to do electrical work and see how they are used to isolate elements from their compounds and how to determine the identity and amount of product formed. Finally, we examine the redox system that generates energy in living cells.

### 21.1 REDOX REACTIONS AND ELECTROCHEMICAL CELLS

Whether an electrochemical process releases or absorbs free energy, it always involves the movement of electrons from one chemical species to another in an oxidation-reduction (redox) reaction. In this section, we review the redox process and describe the half-reaction method of balancing redox reactions that was mentioned in Section 4.5. Then we see how such reactions are used in the two types of electrochemical cells.

## A Quick Review of Oxidation-Reduction Concepts

In electrochemical reactions, as in any redox process, oxidation is the loss of electrons, and reduction is the gain of electrons. An oxidizing agent is the species that does the oxidizing, taking electrons from the substance being oxidized. A reducing agent is the species that does the reducing, giving electrons to the substance being reduced. After the reaction, the oxidized substance has a higher (more positive or less negative) oxidation number (O.N.), and the reduced substance has a lower (less positive or more negative) one. Keep in mind three key points:

- Oxidation (electron loss) always accompanies reduction (electron gain).
- The oxidizing agent is reduced, and the reducing agent is oxidized.
- The total number of electrons gained by the atoms/ions of the oxidizing agent always equals the total number lost by the atoms/ions of the reducing agent.

## Concepts \& Skills to Review before you study this chapter

- redox terminology (Section 4.5 and Interchapter Topic 5)
- balancing redox reactions (Section 4.5)
- activity series of the metals (Section 4.6)
- free energy, work, and equilibrium (Sections 20.3 and 20.4)
- $Q$ vs. $K$ (Section 17.4) and $\Delta G$ vs. $\Delta G^{\circ}$ (Section 20.4)

The Electrochemical Future Is Here As the combustion products of coal and gasoline continue to threaten our atmosphere, a new generation of electrochemical devices is being developed. Batterygasoline hybrid cars are already common, achieving much higher mileage than traditional gasoline-powered cars. Soon, electric cars, powered by banks of advanced fuel cells, may reduce the need for gasoline to a minimum. Every major car company has a fuel-cell prototype in operation. And these devices, once used principally on space missions, are now being produced for everyday residential and industrial applications as well.

Figure 21.1 A summary of redox terminology. In the reaction between zinc and hydrogen ion, Zn is oxidized and $\mathrm{H}^{+}$is reduced.

| PROCESS | $\mathrm{Zn}(s)+2 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{H}_{2}(g)$ |
| :--- | :--- |
| OXIDATION <br> - One reactant loses electrons. <br> - Reducing agent is oxidized. | Zinc loses electrons. <br> Zinc is the reducing agent and <br> becomes oxidized. |
| - Oxidation number increases. |  |
| The oxidation number of Zn |  |
| increases from 0 to +2. |  |

Figure 21.1 presents these ideas for the aqueous reaction between zinc metal and a strong acid. Be sure you can identify the oxidation and reduction parts of a redox process. If you're having trouble, you may want to review the full discussion in Chapter 4 and the summary in Topic 5 of the Interchapter.

## Half-Reaction Method for Balancing Redox Reactions

In Chapter 4, two methods for balancing redox reactions were mentioned-the oxidation number method and the half-reaction method-but only the first was discussed in detail (see Sample Problem 4.10, p. 163). The essential difference between the two methods is that the half-reaction method divides the overall redox reaction into oxidation and reduction half-reactions. Each half-reaction is balanced for atoms and chage Then one or both are multiplied by some integer to make electrons gained equal electrons lost, and the half-reactions are recombined to give the balanced redox equation. The half-reaction method offers several advantages for studying electrochemistry:

- It separates the oxidation and reduction steps, which reflects their actual physical separation in electrochemical cells.
- It is readily applied to redox reactions that take place in acidic or basic solution, which is common in these cells.
- It (usually) does not require assigning O.N.s. (In cases where the half-reactions are not obvious, we assign O.N.s to determine which atoms undergo a change and write half-reactions with the species that contain those atoms.)
In general, we begin with a "skeleton" ionic reaction, which shows only the species that are oxidized and reduced. If the oxidized form of a species is on the left side of the skeleton reaction, the reduced form of that species must be on the right, and vice versa. Unless $\mathrm{H}_{2} \mathrm{O}, \mathrm{H}^{+}$, and $\mathrm{OH}^{-}$are being oxidized or reduced, they do not appear in the skeleton reaction. The following steps are used in balancing a redox reaction by the half-reaction method:

Step 1. Divide the skeleton reaction into two half-reactions, each of which contains the oxidized and reduced forms of one of the species. (Which half-reaction is the oxidation and which the reduction becomes clear in the next step.)

Step 2. Balance the atoms and charges in each half-reaction.

- Atoms are balanced in order: atoms other than O and H , then O , and then H .
- Charge is balanced by adding electrons $\left(\mathrm{e}^{-}\right)$. They are added to the left in the reduction half-reaction because the reactant gains them; they are added to the right in the oxidation half-reaction because the reactant loses them.

Step 3. If necessary, multiply one or both half-reactions by an integer to make the number of $\mathrm{e}^{-}$gained in the reduction equal the number lost in the oxidation.

Step 4. Add the balanced half-reactions, and include states of matter.
Step 5. Check that the atoms and charges are balanced.
We'll balance a redox reaction that occurs in acidic solution first and then go through Sample Problem 21.1 to balance one in basic solution.
Balancing Redox Reactions in Acidic Solution When a redox reaction occurs in acidic solution, $\mathrm{H}_{2} \mathrm{O}$ molecules and $\mathrm{H}^{+}$ions are available for balancing. Even though we've usually used $\mathrm{H}_{3} \mathrm{O}^{+}$to indicate the proton in water, we use $\mathrm{H}^{+}$in this chapter because it makes the balanced equations less complex. However, after using $\mathrm{H}^{+}$in this example, we'll balance the same equation with $\mathrm{H}_{3} \mathrm{O}^{+}$just to show you that the only difference is in the number of water molecules needed.

Let's balance the redox reaction between dichromate ion and iodide ion to form chromium(III) ion and solid iodine, which occurs in acidic solution (Figure 21.2). The skeleton ionic reaction shows only the oxidized and reduced species:

$$
\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+\mathrm{I}^{-}(a q) \longrightarrow \mathrm{Cr}^{3+}(a q)+\mathrm{I}_{2}(s) \quad \text { [acidic solution] }
$$

Step 1. Divide the reaction into half-reactions, each of which contains the oxidized and reduced forms of one species. The two chromium species make up one half-reaction, and the two iodine species make up the other:

$$
\begin{aligned}
\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-} & \longrightarrow \mathrm{Cr}^{3+} \\
\mathrm{I}^{-} & \longrightarrow \mathrm{I}_{2}
\end{aligned}
$$

Step 2. Balance atoms and charges in each half-reaction. We use $\mathrm{H}_{2} \mathrm{O}$ to balance O atoms, $\mathrm{H}^{+}$to balance H atoms, and $\mathrm{e}^{-}$to balance positive charges.

- For the $\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-} / \mathrm{Cr}^{3+}$ half-reaction:
a. Balance atoms other than $O$ and $H$. We balance the two Cr on the left with a coefficient 2 on the right:

b. Balance O atoms by adding $\mathrm{H}_{2} \mathrm{O}$ molecules. Each $\mathrm{H}_{2} \mathrm{O}$ has one O atom, so we add seven $\mathrm{H}_{2} \mathrm{O}$ on the right to balance the seven O in $\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}$ :

$$
\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-} \longrightarrow 2 \mathrm{Cr}^{3+}+7 \mathrm{H}_{2} \mathrm{O}
$$

c. Balance $H$ atoms by adding $H^{+}$ions. Each $\mathrm{H}_{2} \mathrm{O}$ contains two H , and we added seven $\mathrm{H}_{2} \mathrm{O}$, so we add $14 \mathrm{H}^{+}$ions on the left:

$$
14 \mathrm{H}^{+}+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-} \longrightarrow 2 \mathrm{Cr}^{3+}+7 \mathrm{H}_{2} \mathrm{O}
$$

d. Balance charge by adding electrons. Each $\mathrm{H}^{+}$ion has a $1+$ charge, and 14 $\mathrm{H}^{+}$plus $\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}$ gives $12+$ on the left. Two $\mathrm{Cr}^{3+}$ give $6+$ on the right. There is an excess of $6+$ on the left, so we add six $\mathrm{e}^{-}$on the left:

$$
6 \mathrm{e}^{-}+14 \mathrm{H}^{+}+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-} \longrightarrow 2 \mathrm{Cr}^{3+}+7 \mathrm{H}_{2} \mathrm{O}
$$

This half-reaction is balanced, and we see it is the reduction because electrons appear on the left, as reactants: the reactant $\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}$ gains electrons (is reduced), so $\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}$ is the oxidizing agent. (Note that the O.N. of Cr decreases from +6 on the left to +3 on the right.)

- For the $\mathrm{I}^{-} / \mathrm{I}_{2}$ half-reaction:
a. Balance atoms other than $O$ and $H$. Two I atoms on the right require a coefficient 2 on the left:

$$
2 \mathrm{I}^{-} \longrightarrow \mathrm{I}_{2}
$$

b. Balance O atoms with $\mathrm{H}_{2} \mathrm{O}$. Not needed; there are no O atoms.
c. Balance H atoms with $\mathrm{H}^{+}$. Not needed; there are no H atoms.
d. Balance charge with $e^{-}$. To balance the $2-$ on the left, we add two $\mathrm{e}^{-}$on the right:

$$
2 \mathrm{I}^{-} \longrightarrow \mathrm{I}_{2}+2 \mathrm{e}^{-}
$$

This half-reaction is balanced, and it is the oxidation because electrons appear on the right, as products: the reactant $\mathrm{I}^{-}$loses electrons (is oxidized), so $\mathrm{I}^{-}$is the reducing agent. (Note that the O.N. of I increases from -1 to 0 .)

Figure 21.2 The redox reaction between dichromate ion and iodide ion. When $\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}$ (left) and I- (center) are mixed in acid solution, they react to form $\mathrm{Cr}^{3+}$ and $\mathrm{I}_{2}$ (right).

Step 3. Multiply each half-reaction, if necessary, by an integer so that the number of $\mathrm{e}^{-}$lost in the oxidation equals the number of $\mathrm{e}^{-}$gained in the reduction. Two $\mathrm{e}^{-}$are lost in the oxidation and six $\mathrm{e}^{-}$are gained in the reduction, so we multiply the oxidation by 3 :

$$
\begin{aligned}
3\left(2 \mathrm{I}^{-}\right. & \left.\longrightarrow \mathrm{I}_{2}+2 \mathrm{e}^{-}\right) \\
6 \mathrm{I}^{-} & \longrightarrow 3 \mathrm{I}_{2}+6 \mathrm{e}^{-}
\end{aligned}
$$

Step 4. Add the half-reactions together, canceling substances that appear on both sides, and include states of matter. In this example, only the electrons cancel:

$$
\begin{aligned}
& 6 \mathrm{e}^{-}+14 \mathrm{H}^{+}+\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-} \longrightarrow 2 \mathrm{Cr}^{3+}+7 \mathrm{H}_{2} \mathrm{O} \\
& 6 \mathrm{I}^{-} \longrightarrow 3 \mathrm{I}_{2}+6 \mathrm{e}^{-} \\
& 6 \mathrm{I}^{-}(a q)+14 \mathrm{H}^{+}(a q)+\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}(a q) \longrightarrow 3 \mathrm{I}_{2}(s)+7 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{Cr}^{3+}(a q)
\end{aligned}
$$

Step 5. Check that atoms and charges balance:
Reactants ( $6 \mathrm{I}, 14 \mathrm{H}, 2 \mathrm{Cr}, 7 \mathrm{O} ; 6+$ ) $\longrightarrow$ products $(6 \mathrm{I}, 14 \mathrm{H}, 2 \mathrm{Cr}, 7 \mathrm{O} ; 6+$ )
Balancing a Redox Reaction Using $\mathrm{H}_{3} \mathrm{O}^{+}$Now let's balance the reduction halfreaction with $\mathrm{H}_{3} \mathrm{O}^{+}$as the supplier of H atoms. In step 2, balancing Cr atoms and balancing O atoms with $\mathrm{H}_{2} \mathrm{O}$ are the same as before, so we start with

$$
\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-} \longrightarrow 2 \mathrm{Cr}^{3+}+7 \mathrm{H}_{2} \mathrm{O}
$$

Now we use $\mathrm{H}_{3} \mathrm{O}^{+}$instead of $\mathrm{H}^{+}$to balance H atoms. Because each $\mathrm{H}_{3} \mathrm{O}^{+}$is an $\mathrm{H}^{+}$bonded to an $\mathrm{H}_{2} \mathrm{O}$, we balance the 14 H on the right with $14 \mathrm{H}_{3} \mathrm{O}^{+}$on the left and immediately balance the $\mathrm{H}_{2} \mathrm{O}$ that are part of those $14 \mathrm{H}_{3} \mathrm{O}^{+}$by adding 14 more $\mathrm{H}_{2} \mathrm{O}$ on the right:

$$
14 \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-} \longrightarrow 2 \mathrm{Cr}^{3+}+7 \mathrm{H}_{2} \mathrm{O}+14 \mathrm{H}_{2} \mathrm{O}
$$

Simplifying the right side by taking the sum of the $\mathrm{H}_{2} \mathrm{O}$ molecules gives

$$
14 \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-} \longrightarrow 2 \mathrm{Cr}^{3+}+21 \mathrm{H}_{2} \mathrm{O}
$$

 $\mathrm{e}^{-}$on the left, and we obtain the balanced reduction half-reaction:

$$
6 \mathrm{e}^{-}+14 \mathrm{H}_{3} \mathrm{O}^{+}+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-} \longrightarrow 2 \mathrm{Cr}^{3+}+21 \mathrm{H}_{2} \mathrm{O}
$$

Adding the balanced oxidation half-reaction gives the balanced redox equation:

$$
6 \mathrm{I}^{-}(a q)+14 \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q) \longrightarrow 3 \mathrm{I}_{2}(s)+21 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{Cr}^{3+}(a q)
$$

Note, as mentioned earlier, that the only difference is the number of $\mathrm{H}_{2} \mathrm{O}$ molecules: there are 14 more $\mathrm{H}_{2} \mathrm{O}$ (21 instead of 7 ) from the $14 \mathrm{H}_{3} \mathrm{O}^{+}$.

To depict the reaction even more accurately, we could show the metal ion in its hydrated form, which would also affect only the total number of $\mathrm{H}_{2} \mathrm{O}$ :

$$
6 \mathrm{I}^{-}(a q)+14 \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q) \longrightarrow 3 \mathrm{I}_{2}(s)+9 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q)
$$

Although these added steps present the species in solution more accurately, they change only the number of water molecules and make balancing more difficult; thus, they detract somewhat from the key chemical event-the redox change. Therefore, we'll employ the method that uses $\mathrm{H}^{+}$to balance H atoms.
Balancing Redox Reactions in Basic Solution As you just saw, in acidic solution, $\mathrm{H}_{2} \mathrm{O}$ molecules and $\mathrm{H}^{+}$(or $\mathrm{H}_{3} \mathrm{O}^{+}$) ions are available for balancing. As Sample Problem 21.1 shows, in basic solution, $\mathrm{H}_{2} \mathrm{O}$ molecules and $\mathrm{OH}^{-}$ions are available. Only one additional step is needed to balance a redox equation that takes place in basic solution. It appears after both half-reactions have first been balanced as if they took place in acidic solution (steps 1 and 2), the $\mathrm{e}^{-}$lost have been made equal to the $\mathrm{e}^{-}$gained (step 3), and the half-reactions have been combined (step 4). At this point, we add one $\mathrm{OH}^{-}$ion to both sides of the equation for every $H^{+}$ion present. (We label this step " 4 Basic.") The $\mathrm{H}^{+}$ions on one side are combined with the added $\mathrm{OH}^{-}$ions to form $\mathrm{H}_{2} \mathrm{O}$, and $\mathrm{OH}^{-}$ions appear on the other side of the equation. Excess $\mathrm{H}_{2} \mathrm{O}$ molecules are canceled, and states of matter are identified. Finally, we check that atoms and charges balance (step 5).

## SAMPLE PROBLEM 21.1 Balancing Redox Reactions by the Half-Reaction Method

PROBLEM Permanganate ion is a strong oxidizing agent, and its deep purple color makes it useful as an indicator in redox titrations (see Figure 4.15, p. 165). It reacts in basic solution with the oxalate ion to form carbonate ion and solid manganese dioxide. Balance the skeleton ionic equation for the reaction between $\mathrm{NaMnO}_{4}$ and $\mathrm{Na}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$ in basic solution:

$$
\mathrm{MnO}_{4}^{-}(a q)+\mathrm{C}_{2} \mathrm{O}_{4}^{2-}(a q) \longrightarrow \mathrm{MnO}_{2}(s)+\mathrm{CO}_{3}^{2-}(a q) \quad[\text { basic solution }]
$$

PLAN We proceed through step 4 as if this took place in acidic solution. Then, we add the appropriate number of $\mathrm{OH}^{-}$ions and cancel excess $\mathrm{H}_{2} \mathrm{O}$ molecules (step 4 Basic).

## SOLUTION

1. Divide into half-reactions.

$$
\mathrm{MnO}_{4}^{-} \longrightarrow \mathrm{MnO}_{2}
$$

2. Balance.
a. Atoms other than O and H , Not needed
b. O atoms with $\mathrm{H}_{2} \mathrm{O}$,

$$
\mathrm{MnO}_{4}^{-} \longrightarrow \mathrm{MnO}_{2}+2 \mathrm{H}_{2} \mathrm{O}
$$

c. H atoms with $\mathrm{H}^{+}$,

$$
4 \mathrm{H}^{+}+\mathrm{MnO}_{4}^{-} \longrightarrow \mathrm{MnO}_{2}+2 \mathrm{H}_{2} \mathrm{O}
$$

d. Charge with $\mathrm{e}^{-}$,

$$
3 \mathrm{e}^{-}+4 \mathrm{H}^{+}+\mathrm{MnO}_{4}^{-} \longrightarrow \underset{[\text { reduction] }}{ } \mathrm{MnO}_{2}+2 \mathrm{H}_{2} \mathrm{O}
$$

$$
\mathrm{C}_{2} \mathrm{O}_{4}^{2-} \longrightarrow \mathrm{CO}_{3}^{2-}
$$

a. Atoms other than O and H , $\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-} \longrightarrow 2 \mathrm{CO}_{3}{ }^{2-}$
b. O atoms with $\mathrm{H}_{2} \mathrm{O}$,
$2 \mathrm{H}_{2} \mathrm{O}+\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-} \longrightarrow 2 \mathrm{CO}_{3}{ }^{2-}$
c. H atoms with $\mathrm{H}^{+}$,
$2 \mathrm{H}_{2} \mathrm{O}+\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-} \longrightarrow 2 \mathrm{CO}_{3}{ }^{2-}+4 \mathrm{H}^{+}$
d. Charge with $\mathrm{e}^{-}$,
$2 \mathrm{H}_{2} \mathrm{O}+\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-} \longrightarrow 2 \mathrm{CO}_{3}{ }^{2-}+4 \mathrm{H}^{+}+2 \mathrm{e}^{-}$
3. Multiply each half-reaction, if necessary, by some integer to make $\mathrm{e}^{-}$lost equal $\mathrm{e}^{-}$gained.

$$
\begin{array}{cc}
2\left(3 \mathrm{e}^{-}+4 \mathrm{H}^{+}+\mathrm{MnO}_{4}^{-} \longrightarrow \mathrm{MnO}_{2}+2 \mathrm{H}_{2} \mathrm{O}\right) & 3\left(2 \mathrm{H}_{2} \mathrm{O}+\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-} \longrightarrow 2 \mathrm{CO}_{3}^{2-}+4 \mathrm{H}^{+}+2 \mathrm{e}^{-}\right) \\
6 \mathrm{e}^{-}+8 \mathrm{H}^{+}+2 \mathrm{MnO}_{4}^{-} \longrightarrow 2 \mathrm{MnO}_{2}+4 \mathrm{H}_{2} \mathrm{O} & 6 \mathrm{H}_{2} \mathrm{O}+3 \mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-} \longrightarrow 6 \mathrm{CO}_{3}^{2-}+12 \mathrm{H}^{+}+6 \mathrm{e}^{-}
\end{array}
$$

4. Add half-reactions, and cancel substances appearing on both sides.

The six $\mathrm{e}^{-}$cancel, eight $\mathrm{H}^{+}$cancel to leave four $\mathrm{H}^{+}$on the right, and four $\mathrm{H}_{2} \mathrm{O}$ cancel to leave two $\mathrm{H}_{2} \mathrm{O}$ on the left:

$$
\begin{aligned}
& 6 \mathrm{e}^{-}+8 \mathrm{H}^{+}+2 \mathrm{MnO}_{4}^{-} \longrightarrow 2 \mathrm{MnO}_{2}+4 \mathrm{H}_{2} \mathrm{O} \\
& 26 \mathrm{H}_{2} \mathrm{O}+3 \mathrm{C}_{2} \mathrm{O}_{4}^{2-} \longrightarrow 6 \mathrm{CO}_{3}^{2-}+412 \mathrm{H}^{+}+6 \mathrm{e}^{-} \\
& 2 \mathrm{MnO}_{4}^{-}+2 \mathrm{H}_{2} \mathrm{O}+3 \mathrm{C}_{2} \mathrm{O}_{4}^{2-} \longrightarrow 2 \mathrm{MnO}_{2}+6 \mathrm{CO}_{3}^{2-}+4 \mathrm{H}^{+}
\end{aligned}
$$

4 Basic. Add $\mathrm{OH}^{-}$to both sides to neutralize $\mathrm{H}^{+}$, and cancel $\mathrm{H}_{2} \mathrm{O}$.
Adding four $\mathrm{OH}^{-}$to both sides forms four $\mathrm{H}_{2} \mathrm{O}$ on the right, two of which cancel the two $\mathrm{H}_{2} \mathrm{O}$ on the left, leaving two $\mathrm{H}_{2} \mathrm{O}$ on the right:

$$
\begin{aligned}
& 2 \mathrm{MnO}_{4}^{-}+2 \mathrm{H}_{2} \mathrm{O}+3 \mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}+4 \mathrm{OH}^{-} \longrightarrow 2 \mathrm{MnO}_{2}+6 \mathrm{CO}_{3}{ }^{2-}+\left[4 \mathrm{H}^{+}+4 \mathrm{OH}^{-}\right] \\
& 2 \mathrm{MnO}_{4}^{-}+2 \mathrm{H}_{2} \mathrm{O}+3 \mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}+4 \mathrm{OH}^{-} \longrightarrow 2 \mathrm{MnO}_{2}+6 \mathrm{CO}_{3}{ }^{2-}+24 \mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

Including states of matter gives the final balanced equation:
$2 \mathrm{MnO}_{4}{ }^{-}(a q)+3 \mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(a q)+4 \mathrm{OH}^{-}(a q) \longrightarrow 2 \mathrm{MnO}_{2}(s)+6 \mathrm{CO}_{3}{ }^{2-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)$
5. Check that atoms and charges balance.

$$
(2 \mathrm{Mn}, 24 \mathrm{O}, 6 \mathrm{C}, 4 \mathrm{H} ; 12-) \longrightarrow(2 \mathrm{Mn}, 24 \mathrm{O}, 6 \mathrm{C}, 4 \mathrm{H} ; 12-)
$$

COMMENT As a final step, we can obtain the balanced molecular equation for this reaction by noting the number of moles of each anion in the balanced ionic equation and adding the correct number of moles of spectator ions (in this case, $\mathrm{Na}^{+}$) to obtain neutral compounds. Thus, for instance, balancing the charge of 2 mol of $\mathrm{MnO}_{4}^{-}$requires 2 mol of $\mathrm{Na}^{+}$, so we have $2 \mathrm{NaMnO}_{4}$. The balanced molecular equation is
$2 \mathrm{NaMnO}_{4}(a q)+3 \mathrm{Na}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(a q)+4 \mathrm{NaOH}(a q) \underset{2 \mathrm{MnO}_{2}(s)+6 \mathrm{Na}_{2} \mathrm{CO}_{3}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)}{ }$
FOLLOW-UP PROBLEM 21.1 Write a balanced molecular equation for the reaction between $\mathrm{KMnO}_{4}$ and KI in basic solution. The skeleton ionic reaction is

$$
\mathrm{MnO}_{4}^{-}(a q)+\mathrm{I}^{-}(a q) \longrightarrow \mathrm{MnO}_{4}^{2-}(a q)+\mathrm{IO}_{3}^{-}(a q) \quad[\text { basic solution }]
$$

The half-reaction method reveals a great deal about redox processes and is essential to understanding electrochemical cells. The major points are

- Any redox reaction can be treated as the sum of a reduction and an oxidation half-reaction.
- Atoms and charge are conserved in each half-reaction.
- Electrons lost in one half-reaction are gained in the other.
- Although the half-reactions are treated separately, electron loss and electron gain occur simultaneously.

## An Overview of Electrochemical Cells

We distinguish two types of electrochemical cells based on the general thermodynamic nature of the reaction:

1. A voltaic cell (or galvanic cell) uses a spontaneous reaction $(\Delta G<0)$ to generate electrical energy. In the cell reaction, the difference in chemical potential energy between higher energy reactants and lower energy products is converted into electrical energy. This energy is used to operate the load-flashlight bulb, CD player, car starter motor, or other electrical device. In other words, the system does work on the surroundings. All batteries contain voltaic cells.
2. An electrolytic cell uses electrical energy to drive a nonspontaneous reaction ( $\Delta G>0$ ). In the cell reaction, electrical energy from an external power supply converts lower energy reactants into higher energy products. Thus, the surroundings do work on the system. Electroplating and recovering metals from ores involve electrolytic cells.
The two types of cell have certain design features in common (Figure 21.3). Two electrodes, which conduct the electricity between cell and surroundings, are dippedingean etectryterandixere dens (usually in aqueous solution) that

Figure 21.3 General characteristics of voltaic and electrolytic cells. A voltaic cell (A) generates energy from a spontaneous reaction ( $\Delta G<0$ ), whereas an electrolytic cell (B) requires energy to drive a nonspontaneous reaction ( $\Delta G>0$ ). In both types of cell, two electrodes dip into electrolyte solutions, and an external circuit provides the means for electrons to flow between them. Most important, notice that oxidation takes place at the anode and reduction takes place at the cathode, but the relative electrode charges are opposite in the two cells.

are involved in the reaction or that carry the charge. An electrode is identified as either anode or cathode depending on the half-reaction that takes place there:

- The oxidation half-reaction occurs at the anode. Electrons are lost by the substance being oxidized (reducing agent) and leave the cell at the anode.
- The reduction half-reaction occurs at the cathode. Electrons are gained by the substance being reduced (oxidizing agent) and enter the cell at the cathode.
As shown in Figure 21.3, the relative charges of the electrodes are opposite in the two types of cell. As you'll see in the following sections, these opposite charges result from the different phenomena that cause the electrons to flow.

## Section Summary

An oxidation-reduction (redox) reaction involves the transfer of electrons from a reducing agent to an oxidizing agent. • The half-reaction method of balancing divides the overall reaction into half-reactions that are balanced separately and then recombined. - The two types of electrochemical cells are based on redox reactions. In a voltaic cell, a spontaneous reaction generates electricity and does work on the surroundings; in an electrolytic cell, the surroundings supply electricity that does work to drive a nonspontaneous reaction. In both types, two electrodes dip into electrolyte solutions; oxidation occurs at the anode, and reduction occurs at the cathode.

### 21.2 VOLTAIC CELLS: USING SPONTANEOUS REACTIONS TO GENERATE ELECTRICAL ENERGY

If you put a strip of zinc metal in a solution of $\mathrm{Cu}^{2+}$ ion, the blue color of the solution fades as a brown-black crust of Cu metal forms on the Zn strip (Figure 21.4). Judging from what we see, the reaction involves the reduction of $\mathrm{Cu}^{2+}$ ion to Cu metal, which must be accompanied dy the pxidation Gf Znnmetal to $\mathrm{Zn}^{2+}$ ion. The overall reaction consists of two half-reactions:

$$
\begin{array}{rll}
\mathrm{Cu}^{2+}(a q)+2 \mathrm{e}^{-} & \longrightarrow \mathrm{Cu}(s) & \text { [reduction] } \\
\mathrm{Zn}(s) \longrightarrow \mathrm{Zn}^{2+}(a q)+2 \mathrm{e}^{-} & & {[\text {oxidation }]} \\
\hline \mathrm{Zn}(s)+\mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{Cu}(s) & & {[\text { overall reaction }]}
\end{array}
$$

Which Half-Reaction Occurs at Which Electrode? Here are some memory aids to help you remember which half-reaction occurs at which electrode:

1. The words anode and oxidation start with vowels; the words cathode and reduction start with consonants.
2. Alphabetically, the $A$ in anode comes before the $C$ in cathode, and the $O$ in oxidation comes before the $R$ in reduction.
3. Look at the first syllables and use your imagination:

ANode, OXidation; REDuction, CAThode $\Rightarrow$ AN OX and a RED CAT

Figure 21.4 The spontaneous reaction between zinc and copper(II) ion. When a strip of zinc metal is placed in a solution of $\mathrm{Cu}^{2+}$ ion, a redox reaction begins (left), in which the zinc is oxidized to $\mathrm{Zn}^{2+}$ and the $\mathrm{Cu}^{2+}$ is reduced to copper metal. As the reaction proceeds (right), the deep blue color of the solution of hydrated $\mathrm{Cu}^{2+}$ ion lightens, and the Cu "plates out" on the Zn and falls off in chunks. (The Cu appears black because it is very finely divided.) At the atomic scale, each Zn atom loses two electrons, which are gained by $\mathrm{a} \mathrm{Cu}^{2+}$ ion. The process is summarized with symbols in the balanced equation.

In the remainder of this section, we examine this spontaneous reaction as the basis of a voltaic (galvanic) cell.

## Construction and Operation of a Voltaic Cell

Electrons are being transferred in the $\mathrm{Zn} / \mathrm{Cu}^{2+}$ reaction (Figure 21.4), but the system does not generate electrical energy because the oxidizing agent $\left(\mathrm{Cu}^{2+}\right)$ and the reducing agent $(\mathrm{Zn})$ are in the same beaker. If, however, the half-reactions are physically separated and connected by an external circuit, the electrons are transferred by traveling through the circuit and an electric current is produced.

This separation of half-reactions is the essential idea behind a voltaic cell (Figure 21.5 A ). The components of each half-reaction are placed in a separate container, or half-cell, which consists of one electrode dipping into an electrolyte solution. The two half-cells are joined by the circuit, which consists of a wire and a salt bridge (the inverted $U$ tube in the figure; we will discuss its function shortly). In order to measure the voltage generated by the cell, a voltmeter is inserted in the path of the wire connecting the electrodes. A switch (not shown) closes (completes) or opens (breaks) the circuit. By convention, the oxidation halfcell (anode compartment) is shown on the left and the reduction half-cell (cathode compartment) on the right. Here are the key points about the $\mathrm{Zn} / \mathrm{Cu}^{2+}$ voltaic cell:

1. The oxidation half-cell. In this case, the anode compartment consists of a zinc bar (the anode) immersed in a $\mathrm{Zn}^{2+}$ electrolyte (such as a solution of zinc sulfate, $\mathrm{ZnSO}_{4}$ ). The zinc bar is the reactant in the oxidation half-reaction, and it conducts the released electrons out of its half-cell.
2. The reduction half-cell. In this case, the cathode compartment consists of a copper bar (the cathode) immersed in a $\mathrm{Cu}^{2+}$ electrolyte [such as a solution of copper(II) sulfate, $\mathrm{CuSO}_{4}$ ]. Copper metal is the product in the reduction halfreaction and the ban conducts electrens into its half-cell.
3. Retative charges on the electrodes. The electrode charges are determined by the source of electrons and the direction of electron flow through the circuit. In this cell, zinc atoms are oxidized at the anode to $\mathrm{Zn}^{2+}$ ions and electrons. The $\mathrm{Zn}^{2+}$ ions enter the solution, while the electrons enter the bar and then the wire. The electrons flow left to right through the wire to the cathode, where $\mathrm{Cu}^{2+}$ ions in the solution accept them and are reduced to Cu atoms. As the cell operates, electrons are continuously generated at the anode and consumed at the cathode. Therefore, the anode has an excess of electrons and a negative charge relative to the cathode. In any voltaic cell, the anode is negative and the cathode is positive.
4. The purpose of the salt bridge. The cell cannot operate unless the circuit is complete. The oxidation half-cell originally contains a neutral solution of $\mathrm{Zn}^{2+}$ and $\mathrm{SO}_{4}{ }^{2-}$ ions, but as Zn atoms in the bar lose electrons, the solution would develop a net positive charge from the $\mathrm{Zn}^{2+}$ ions entering. Similarly, in the reduction half-cell, the neutral solution of $\mathrm{Cu}^{2+}$ and $\mathrm{SO}_{4}{ }^{2-}$ ions would develop a net negative charge as $\mathrm{Cu}^{2+}$ ions leave the solution to form Cu atoms. If the half-cells do not remain neutral, the resulting charge imbalance would stop cell operation. To avoid this situation and enable the cell to operate, the two halfcells are joined by a salt bridge, which acts as a "liquid wire," allowing ions to flow through both compartments and complete the circuit. The salt bridge shown in Figure 21.5 A is an inverted U tube containing a solution of the nonreacting ions $\mathrm{Na}^{+}$and $\mathrm{SO}_{4}{ }^{2-}$ in a gel. The solution cannot pour out, but ions can diffuse through it into or out of the half-cells.

To maintain neutrality in the reduction half-cell (right; cathode compartment) as $\mathrm{Cu}^{2+}$ ions change to Cu atoms, $\mathrm{Na}^{+}$ions move from the salt bridge into the solution (and some $\mathrm{SO}_{4}{ }^{2-}$ ions move from the solution into the salt bridge). Similarly, to maintain neutrality in the oxidation half-cell (left; anode compartment)

A

$$
\mathrm{Zn}(s)+\mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{Cu}(s)
$$

as Zn atoms change to $\mathrm{Zn}^{2+}$ ions, $\mathrm{SO}_{4}{ }^{2-}$ ions move from the salt bridge into that solution (and some $\mathrm{Zn}^{2+}$ ions move from the solution into the salt bridge). Thus, as Figure 21.5A shows, the circuit is completed as electrons move left to right through the wire, while anions move right to left and cations move left to right through the salt bridge.
5. Active vs. inactive electrodes. The electrodes in the $\mathrm{Zn} / \mathrm{Cu}^{2+}$ cell are active because the metal bars themselves are components of the half-reactions. As the cell operates, the mass of the zinc electrode gradually decreases, and the $\left[\mathrm{Zn}^{2+}\right]$ in the anode half-cell increases. At the same time, the mass of the copper electrode increases, and the $\left[\mathrm{Cu}^{2+}\right]$ in the cathode half-cell decreases; we say that the $\mathrm{Cu}^{2+}$ "plates out" on the electrode. Look at Figure 21.5B to see how the electrodes look, removed from their half-cells, after several hours of operation.

For many redox reactions, there are no reactants or products capable of serving as electrodes, so inactive electrodes are used. Most commonly, inactive electrodes are rods of graphite or platinum: they conduct electrons into or out of the half-cells but cannot take part in the half-reactions. In a voltaic cell based on the following half-reactions, for instance, the reacting species cannot act as electrodes:

$$
\begin{array}{cl}
2 \mathrm{I}^{-}(a q) \longrightarrow \mathrm{I}_{2}(s)+2 \mathrm{e}^{-} & \text {[anode; oxidation] } \\
\mathrm{MnO}_{4}^{-}(a q)+8 \mathrm{H}^{+}(a q)+5 \mathrm{e}^{-} \longrightarrow \mathrm{Mn}^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l) & \text { [cathode; reduction] }
\end{array}
$$

Figure 21.5 A voltaic cell based on the zinc-copper reaction. A, The anode halfcell (oxidation) consists of a Zn electrode dipping into a $\mathrm{Zn}^{2+}$ solution. The two electrons generated in the oxidation of each Zn atom move through the Zn bar and the wire, and into the Cu electrode, which dips into a $\mathrm{Cu}^{2+}$ solution in the cathode half-cell (reduction). There, the electrons reduce $\mathrm{Cu}^{2+}$ ions. Thus, electrons flow left to right through electrodes and wire. A salt bridge contains unreactive $\mathrm{Na}^{+}$and $\mathrm{SO}_{4}{ }^{2-}$ ions that maintain neutral charge in the electrolyte solutions: anions in the salt bridge flow to the left, and cations flow to the right. The voltmeter registers the electrical output of the cell. B, After the cell runs for several hours, the Zn anode weighs less because Zn atoms have been oxidized to aqueous $\mathrm{Zn}^{2+}$ ions, and the Cu cathode weighs more because aqueous $\mathrm{Cu}^{2+}$ ions have been reduced to Cu metal.

Oxidation half-reaction $2 \mathrm{I}^{-}(a q) \longrightarrow \mathrm{I}_{2}(s)+2 \mathrm{e}^{-}$

Reduction half-reaction
$\mathrm{MnO}_{4}^{-}(a q)+8 \mathrm{H}^{+}(a q)+5 \mathrm{e}^{-} \longrightarrow$ $\mathrm{Mn}^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(/)$

> | Overall (cell) reaction |
| :---: |
| $2 \mathrm{MnO}_{4}^{-}(a q)+16 \mathrm{H}^{+}(a q)+10 \mathrm{I}^{-}(a q) \longrightarrow$ |
| $2 \mathrm{Mn}^{2+}(a q)+5 \mathrm{I}_{2}(s)+8 \mathrm{H}_{2} \mathrm{O}(I)$ |

Figure 21.6 A voltaic cell using inactive electrodes. The reaction between $I^{-}$and $\mathrm{MnO}_{4}{ }^{-}$in acidic solution does not have species that can be used as electrodes, so inactive graphite (C) electrodes are used.

Therefore, each half-cell consists of inactive electrodes immersed in an electrolyte solution that contains all the reactant species involved in that half-reaction (Figure 21.6). In the anode half-cell, $\mathrm{I}^{-}$ions are oxidized to solid $\mathrm{I}_{2}$. The electrons that are released flow into the graphite anode, through the wire, and into the graphite cathode. From there, the electrons are consumed by $\mathrm{MnO}_{4}{ }^{-}$ions, which are reduced to $\mathrm{Mn}^{2+}$ ions. (A $\mathrm{KNO}_{3}$ salt bridge is used.)

As Figures 21.5A and 21.6 show, there are certain consistent features in the diagram of any voltaic cell. The physical arrangement includes the half-cell containers, electrodes, wire, and salt bridge, and the following details appear:

- Components of the half-cells: electrode materials, electrolyte ions, and other substances involved in the reaction
- Electrode name (anode or cathode) and charge. By convention, the anode compartment always appears on the left.
- Each half-reaction with its half-cell and the overall cell reaction
- Direction of electron flow in the external circuit
- Nature of ions and direction of ion flow in the salt bridge

You'll see how to specify these details and diagram a cell shortly.

## Notation for a Voltaic Cell

A useful shorthand notation describes the components of a voltaic cell. For example, the notation for the $\mathrm{Zn} / \mathrm{Cu}^{2+}$ cell is

$$
\mathrm{Zn}(s)\left|\mathrm{Zn}^{2+}(a q) \| \mathrm{Cu}^{2+}(a q)\right| \mathrm{Cu}(s)
$$

Key parts of the notation are

- The components of the anode compartment (oxidation half-cell) are written to the left of the components of the cathode compartment (reduction half-cell).
A pasmgevertrit tine Fepresent a Cprafe boundary. For example, $\mathrm{Zn}(s)$
$\mathrm{Zn}^{2+}($ aq $)$ indicates that the solid Zn is a different phase from the aqueous $\mathrm{Zn}^{2+}$. A comma separates the half-cell components that are in the same phase. For example, the notation for the voltaic cell housing the reaction between $\mathrm{I}^{-}$ and $\mathrm{MnO}_{4}^{-}$shown in Figure 21.6 is
graphite $\left|\mathrm{I}^{-}(a q)\right| \mathrm{I}_{2}(s) \| \mathrm{H}^{+}(a q), \mathrm{MnO}_{4}^{-}(a q), \mathrm{Mn}^{2+}(a q) \mid$ graphite
That is, in the cathode compartment, $\mathrm{H}^{+}, \mathrm{MnO}_{4}{ }^{-}$, and $\mathrm{Mn}^{2+}$ ions are all in aqueous solution with solid graphite immersed in it. Often, we specify the concentrations of dissolved components; for example, if the concentrations of $\mathrm{Zn}^{2+}$ and $\mathrm{Cu}^{2+}$ are $1 M$, we write

$$
\mathrm{Zn}(s)\left|\mathrm{Zn}^{2+}(1 M) \| \mathrm{Cu}^{2+}(1 M)\right| \mathrm{Cu}(s)
$$

- Half-cell components usually appear in the same order as in the half-reaction, and electrodes appear at the far left and far right of the notation.
- A double vertical line indicates the separated half-cells and represents the phase boundary on either side of the salt bridge (the ions in the salt bridge are omitted because they are not part of the reaction).

## SAMPLE PROBLEM 21.2 Describing a Voltaic Cell with a Diagram and Notation

PROBLEM Draw a diagram, show balanced equations, and write the notation for a voltaic cell that consists of one half-cell with a Cr bar in a $\mathrm{Cr}\left(\mathrm{NO}_{3}\right)_{3}$ solution, another half-cell with an Ag bar in an $\mathrm{AgNO}_{3}$ solution, and a $\mathrm{KNO}_{3}$ salt bridge. Measurement indicates that the Cr electrode is negative relative to the Ag electrode.
PLAN From the given contents of the half-cells, we can write the half-reactions. We must determine which is the anode compartment (oxidation) and which is the cathode (reduction). To do so, we must find the direction of the spontaneous redox reaction, which is
given by the relative electrode charges. Electrons are released into the anode during oxidation, so it has a negative charge. We are told that Cr is negative, so it must be the anode; and, therefore, Ag is the cathode.
SOLUTION Writing the balanced half-reactions. The Ag electrode is positive, so the halfreaction consumes $\mathrm{e}^{-}$:

$$
\mathrm{Ag}^{+}(a q)+\mathrm{e}^{-} \longrightarrow \mathrm{Ag}(s) \quad \text { [reduction; cathode] }
$$

The Cr electrode is negative, so the half-reaction releases $\mathrm{e}^{-}$:

$$
\mathrm{Cr}(s) \longrightarrow \mathrm{Cr}^{3+}(a q)+3 \mathrm{e}^{-} \quad \text { [oxidation; anode] }
$$

Writing the balanced overall cell reaction. We triple the reduction half-reaction in order to balance $\mathrm{e}^{-}$, and then we combine the half-reactions to obtain the overall reaction:

$$
\mathrm{Cr}(s)+3 \mathrm{Ag}^{+}(a q) \longrightarrow \mathrm{Cr}^{3+}(a q)+3 \mathrm{Ag}(s)
$$

Determining direction of electron and ion flow. The released $\mathrm{e}^{-}$in the Cr electrode (negative) flow through the external circuit to the Ag electrode (positive). $\mathrm{As}_{\mathrm{Cr}}{ }^{3+}$ ions enter the anode electrolyte, $\mathrm{NO}_{3}{ }^{-}$ions enter from the salt bridge to maintain neutrality. $\mathrm{As} \mathrm{Ag}^{+}$ ions leave the cathode electrolyte and plate out on the Ag electrode, $\mathrm{K}^{+}$ions enter from the salt bridge to maintain neutrality. The diagram of this cell is shown in the margin. Writing the cell notation:

$$
\mathrm{Cr}(s)\left|\mathrm{Cr}^{3+}(a q) \| \mathrm{Ag}^{+}(a q)\right| \operatorname{Ag}(s)
$$

CHECK Always be sure that the half-reactions and cell reaction are balanced, the half-cells contain all components of the half-reactions, and the electron and ion flow are shown. You should be able to write the half-reactions from the cell notation as a check.
COMMENT The key to diagramming a voltaic cell is to use the direction of the spontaneous reaction to identify the oxidation (anode; negative) and reduction (cathode; positive) half-reactions.
FOLLOW-UP PROBLEM 21.2 In one compartment of a voltaic cell, a graphite rod dips into an acidic solution of $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ and $\mathrm{Cr}\left(\mathrm{NO}_{3}\right)_{3}$; in the other compartment, a tin bar dips into a $\mathrm{Sn}\left(\mathrm{NO}_{3}\right)_{2}$ solution. $\mathrm{A}_{\mathrm{KNO}}^{3}$ salt bridge joins them. The tin electrode is negative relative to the graphite. Draw a diagram of the cell, show the balanced equations, and write the cell notation.

## Why Does a Voltaic Cell Work?

By placing a lightbulb in the circuit or looking at the voltmeter, we can see that the $\mathrm{Zn} / \mathrm{Cu}^{2+}$ cell generates electrical energy. But what principle explains how the reaction takes place, and why do electrons flow in the direction shown?

Let's examine what happens when the switch is open and no reaction is occurring. In each half-cell, we can consider the metal electrode to be in equilibrium with the metal ions in the electrolyte and the electrons residing in the metal:

$$
\begin{aligned}
& \mathrm{Zn}(s) \rightleftharpoons \mathrm{Zn}^{2+}(a q)+2 \mathrm{e}^{-}(\text {in } \mathrm{Zn} \text { metal }) \\
& \mathrm{Cu}(s) \rightleftharpoons \mathrm{Cu}^{2+}(a q)+2 \mathrm{e}^{-}(\text {in } \mathrm{Cu} \text { metal })
\end{aligned}
$$

From the direction of the overall spontaneous reaction, we know that Zn gives up its electrons more easily than Cu does; thus, Zn is a stronger reducing agent. Therefore, the equilibrium position of the Zn half-reaction lies farther to the right: Zn produces more electrons than Cu does. You might think of the electrons in the Zn electrode as being subject to a greater electron "pressure" than those in the Cu electrode, a greater potential energy (referred to as electrical potential) ready to "push" them through the circuit. Close the switch, and electrons flow from the Zn to the Cu electrode to equalize this difference in electrical potential. The flow disturbs the equilibrium at each electrode. The Zn half-reaction shifts to the right to restore the electrons flowing out, and the Cu half-reaction shifts to the left to remove the electrons flowing in. Thus, the spontaneous reaction occurs as a result of the different abilities of these metals to give up their electrons and the ability of the electrons to flow through the circuit.

Oxidation half-reaction
$\mathrm{Cr}(\mathrm{s}) \longrightarrow \mathrm{Cr}^{3+}(a q)+3 \mathrm{e}^{-}$

Overall (cell) reaction

Electron Flow and Water Flow Consider this analogy between electron "pressure" and water pressure. A U tube (cell) is separated into two arms (two half-cells) by a stopcock (switch), and the two arms contain water at different heights (the half-cells contain half-reactions with different electrical potentials). Open the stopcock (close the switch), and the different heights (potential difference) become equal as water flows (electrons flow and current is generated).

## Section Summary

A voltaic cell consists of oxidation (anode) and reduction (cathode) half-cells, connected by a wire to conduct electrons and a salt bridge to maintain charge neutrality as the cell operates. - Electrons move from anode (left) to cathode (right), while cations move from the salt bridge into the cathode half-cell and anions from the salt bridge into the anode half-cell. - The cell notation shows the species and their phases in each half-cell, as well as the direction of current flow. - A voltaic cell operates because species in the two half-cells differ in their tendency to lose electrons.

### 21.3 CELL POTENTIAL: OUTPUT OF A VOLTAIC CELL

The purpose of a voltaic cell is to convert the free energy change of a spontaneous reaction into the kinetic energy of electrons moving through an external circuit (electrical energy). This electrical energy is proportional to the difference in electrical potential between the two electrodes, which is called the cell potential ( $\boldsymbol{E}_{\text {cell }}$ ); it is also called the voltage of the cell or the electromotive force (emf).

Electrons flow spontaneously from the negative to the positive electrode, that is, toward the electrode with the more positive electrical potential. Thus, when the cell operates spontaneously, there is a positive cell potential:

$$
\begin{equation*}
E_{\text {cell }}>0 \text { for a spontaneous process } \tag{21.1}
\end{equation*}
$$

The more positive $E_{\text {cell }}$ is, the more work the cell can do, and the farther the reaction proceeds to the right as written. A negative cell potential, on the other hand, is associated with a nonsppntaneous cell reaction. If $E_{\text {cell }}=0$, the reaction has reacheqequifibrimm the the dellando rofmore work. (There is a clear relationship between $E_{\text {cell }}, K$, and $\Delta G$ that we'll discuss in Section 21.4.)

How are the units of cell potential related to those of energy available to do work? As you've seen, work is done when charge moves between electrode compartments that differ in electrical potential. The SI unit of electrical potential is the volt (V), and the SI unit of electrical charge is the coulomb (C). By definition, for two electrodes that differ by 1 volt of electrical potential, 1 joule of energy is released (that is, 1 joule of work can be done) for each coulomb of charge that moves between the electrodes. Thus,

$$
\begin{equation*}
1 \mathrm{~V}=1 \mathrm{~J} / \mathrm{C} \tag{21.2}
\end{equation*}
$$

Table 21.1 lists the voltages of some commercial and natural voltaic cells. Next, we'll see how to measure cell potential.

Table 21.1 Voltages of Some Voltaic Cells

| Voltaic Cell | Voltage (V) |
| :--- | :---: |
| Common alkaline flashlight battery | 1.5 |
| Lead-acid car battery $(6$ cells $=12 \mathrm{~V})$ | 2.0 |
| Calculator battery (mercury) | 1.3 |
| Lithium-ion laptop battery | 3.7 |
| Electric eel $(\sim 5000$ cells in 6-ft eel $=750 \mathrm{~V})$ | 0.15 |
| Nerve of giant squid (across cell membrane) | 0.070 |

## Standard Cell Potentials

The measured potential of a voltaic cell is affected by changes in concentration as the reaction proceeds and by energy losses due to heating of the cell and the external circuit. Therefore, in order to compare the output of different cells, we obtain a standard cell potential ( $\boldsymbol{E}_{\text {cell }}^{\circ}$ ), the potential measured at a specified temperature (usually 298 K ) with no current flowing* and all components in their standard states: 1 atm for gases, 1 M for solutions, the pure solid for electrodes. When the zinc-copper cell that we diagrammed in Figure 21.5 begins operating under standard state conditions, that is, when $\left[\mathrm{Zn}^{2+}\right]=\left[\mathrm{Cu}^{2+}\right]=1 \mathrm{M}$, the cell produces 1.10 V at 298 K (Figure 21.7):

$$
\mathrm{Zn}(s)+\mathrm{Cu}^{2+}(a q ; 1 M) \longrightarrow \mathrm{Zn}^{2+}(a q ; 1 M)+\mathrm{Cu}(s) \quad E_{\mathrm{cell}}^{\circ}=1.10 \mathrm{~V}
$$

Standard Electrode (Half-Cell) Potentials Just as each half-reaction makes up part of the overall reaction, the potential of each half-cell makes up a part of the overall cell potential. The standard electrode potential ( $\boldsymbol{E}_{\text {half-cell }}^{\circ}$ ) is the potential associated with a given half-reaction (electrode compartment) when all the components are in their standard states.

By convention, a standard electrode potential always refers to the halfreaction written as a reduction. For the zinc-copper reaction, for example, the standard electrode potentials for the zinc half-reaction ( $E_{\text {zinc }}^{\circ}$, anode compartment) and for the copper half-reaction ( $E_{\text {copper }}^{\circ}$, cathode compartment) refer to the processes written as reductions:

$$
\begin{array}{lll}
\mathrm{Zn}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Zn}(s) & E_{\text {Zinc }}^{\circ}\left(E_{\text {anode }}^{\circ}\right) & \text { [reduction }] \\
\mathrm{Cu}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu}(s) & E_{\text {copper }}^{\circ}\left(E_{\text {cathode }}^{\circ}\right) & \text { [reduction }]
\end{array}
$$

The overall cell reaction involves the oxidation of zinc at the anode, not the reduction of $\mathrm{Zn}^{2+}$, so we reverse the zinc half-reaction:

$$
\begin{aligned}
& \mathrm{Cu}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu}(s) \quad \text { [reduction] }
\end{aligned}
$$

The overall redox reaction is the sum of these half-reactions:

$$
\mathrm{Zn}(s)+\mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{Cu}(s)
$$

Because electrons flow spontaneously toward the copper electrode (cathode), it must have a more positive $E_{\text {half-cell }}^{\circ}$ than the zinc electrode (anode). Therefore, to obtain a positive $E_{\mathrm{cell}}^{\circ}$, we subtract $E_{\text {zinc }}^{\circ}$ from $E_{\mathrm{copper}}^{\circ}$ :

$$
E_{\text {cell }}^{\circ}=E_{\text {copper }}^{\circ}-E_{\text {zinc }}^{\circ}
$$

We can generalize this result for any voltaic cell: the standard cell potential is the difference between the standard electrode potential of the cathode (reduction) half-cell and the standard electrode potential of the anode (oxidation) half-cell:

$$
\begin{equation*}
E_{\mathrm{cell}}^{\circ}=E_{\mathrm{cathode} \text { (reduction) }}^{\circ}-E_{\text {anode (oxidation) }}^{\circ} \tag{21.3}
\end{equation*}
$$

For a spontaneous reaction at standard conditions, $E_{\mathrm{cell}}^{\circ}>0$.
Determining $E_{\text {half-cell: The }}^{\circ}$ Standard Hydrogen Electrode What portion of $E_{\text {cell }}^{\circ}$ for the zinc-copper reaction is contributed by the anode half-cell (oxidation of Zn ) and what portion by the cathode half-cell (reduction of $\mathrm{Cu}^{2+}$ )? That is, how can we know half-cell potentials if we can only measure the potential of the complete cell? Half-cell potentials, such as $E_{\text {zinc }}^{\circ}$ and $E_{\text {copper }}^{\circ}$, are not absolute quantities, but rather are values relative to that of a standard. This standard reference

[^32]

Figure 21.7 Measurement of a standard cell potential. The zinc-copper cell, operating at 298 K under standardstate conditions, produces a voltage of 1.10 V .
half-cell has its standard electrode potential defined as zero ( $E_{\text {reference }}^{\circ} \equiv 0.00 \mathrm{~V}$ ). The standard reference half-cell is a standard hydrogen electrode, which consists of a specially prepared platinum electrode immersed in a $1 M$ aqueous solution of a strong acid, $\mathrm{H}^{+}(a q)$ [or $\left.\mathrm{H}_{3} \mathrm{O}^{+}(a q)\right]$, through which $\mathrm{H}_{2}$ gas at 1 atm is bubbled. Thus, the reference half-reaction is

$$
2 \mathrm{H}^{+}(a q ; 1 M)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{H}_{2}(g ; 1 \mathrm{~atm}) \quad E_{\text {reference }}^{\circ}=0.00 \mathrm{~V}
$$

Now we can construct a voltaic cell consisting of this reference half-cell and another half-cell whose potential we want to determine. With $E_{\text {reference }}^{\circ}$ defined as zero, the overall $E_{\text {cell }}^{\circ}$ allows us to find the unknown standard electrode potential, $E_{\text {unknown }}^{\circ}$. When $\mathrm{H}_{2}$ is oxidized, the reference half-cell is the anode, and so reduction occurs at the unknown half-cell:

$$
E_{\mathrm{cell}}^{\circ}=E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ}=E_{\text {unknown }}^{\circ}-E_{\text {reference }}^{\circ}=E_{\text {unknown }}^{\circ}-0.00 \mathrm{~V}=E_{\text {unknown }}^{\circ}
$$

When $\mathrm{H}^{+}$is reduced, the reference half-cell is the cathode, and so oxidation occurs at the unknown half-cell:

$$
E_{\text {cell }}^{\circ}=E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ}=E_{\text {reference }}^{\circ}-E_{\text {unknown }}^{\circ}=0.00 \mathrm{~V}-E_{\text {unknown }}^{\circ}=-E_{\text {unknown }}^{\circ}
$$

Figure 21.8 shows a voltaic cell that has the $\mathrm{Zn} / \mathrm{Zn}^{2+}$ half-reaction in one compartment and the $\mathrm{H}^{+} / \mathrm{H}_{2}$ (or $\mathrm{H}_{3} \mathrm{O}^{+} / \mathrm{H}_{2}$ ) half-reaction in the other. The zinc electrode is negative relative to the hydrogen electrode, so we know that the zinc is being oxidized and is the anode. The measured $E_{\text {cell }}^{\circ}$ is +0.76 V , and we use this value to find the unknown standard electrode potential, $E_{\text {zinc }}^{\circ}$ :

| $2 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(g)$ | $E_{\text {reference }}^{\circ}=0.00 \mathrm{~V}$ | [cathode; reduction] |
| :---: | :---: | :---: |
| $\mathrm{Zn}(s) \longrightarrow \mathrm{Zn}^{2+}(a q)+2 \mathrm{e}^{-}$ | $E_{\text {zinc }}^{\circ}=? \mathrm{~V}$ | [anode; oxidation] |
| $\mathrm{Zn}(s)+2 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{H}_{2}(g)$ | $E_{\text {cell }}^{\circ}=0.76 \mathrm{~V}$ |  |
| $E_{\text {cell }}^{\circ}=E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ}=E_{\text {reference }}^{\circ}-E_{\text {zinc }}^{\circ}$ |  |  |

Figure 21.8 Determining an unknown $E_{\text {half-cell }}^{\circ}$ with the standard reference (hydrogen) electrode. A voltaic cell has the $\mathrm{Zn} / \mathrm{Zn}^{2+}$ halfreaction in one half-cell and the hydrogen reference half-reaction in the other. The magnified view of the hydrogen half-reaction shows two $\mathrm{H}_{3} \mathrm{O}^{+}$ions being reduced to two $\mathrm{H}_{2} \mathrm{O}$ molecules and an $\mathrm{H}_{2}$ molecule,
which enters the $\mathrm{H}_{2}$ bubble. The $\mathrm{Zn} / \mathrm{Zn}^{2+}$ half-cell potential is negative (anode), and the cell potential is 0.76 V . The potential of the standard reference electrode is defined as 0.00 V , so the cell potential equals the negative of the anode potential; that is,

$$
0.76 \mathrm{~V}=0.00 \mathrm{~V}-E_{\text {zinc }}^{\mathrm{o}} \quad \text { so } \quad E_{\text {zinc }}^{\circ}=-0.76 \mathrm{~V}
$$

Now let's return to the zinc-copper cell and use the measured value of $E_{\text {cell }}^{\circ}$ $(1.10 \mathrm{~V})$ and the value we just found for $E_{\text {zinc }}^{\circ}$ to calculate $E_{\text {copper }}^{\circ}$ :

$$
\begin{aligned}
E_{\text {cell }}^{\circ} & =E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ}=E_{\text {copper }}^{\circ}-E_{\text {zinc }}^{\circ} \\
E_{\text {copper }}^{\circ} & =E_{\text {cell }}^{\circ}+E_{\text {zinc }}^{\circ}=1.10 \mathrm{~V}+(-0.76 \mathrm{~V})=0.34 \mathrm{~V}
\end{aligned}
$$

By continuing this process of constructing cells with one known and one unknown electrode potential, we can find many other standard electrode potentials. Let's go over these ideas once more with a sample problem.

SAMPLE PROBLEM 21.3 Calculating an Unknown $E_{\text {half-cell }}^{\circ}$ from $E_{\text {cell }}^{\circ}$
PROBLEM A voltaic cell houses the reaction between aqueous bromine and zinc metal:

$$
\mathrm{Br}_{2}(a q)+\mathrm{Zn}(s) \longrightarrow \mathrm{Zn}^{2+}(a q)+2 \mathrm{Br}^{-}(a q) \quad E_{\mathrm{cell}}^{\circ}=1.83 \mathrm{~V}
$$

Calculate $E_{\text {bromine }}^{\circ}$, given $E_{\text {zinc }}^{\circ}=-0.76 \mathrm{~V}$.
PLAN $E_{\text {cell }}^{\circ}$ is positive, so the reaction is spontaneous as written. By dividing the reaction into half-reactions, we see that $\mathrm{Br}_{2}$ is reduced and Zn is oxidized; thus, the zinc half-cell contains the anode. We use Equation 21.3 to find $E_{\text {unknown }}^{\circ}\left(E_{\text {bromine }}^{\circ}\right)$.
SOLUTION Dividing the reaction into half-reactions:

$$
\begin{aligned}
\mathrm{Br}_{2}(a q)+2 \mathrm{e}^{-} & \longrightarrow \mathrm{Br}^{-}(a q) & E_{\text {unknown }}^{\circ} & =E_{\text {bromine }}^{\circ}=? \mathrm{~V} \\
\mathrm{Zn}(s) & \longrightarrow \mathrm{Zn}^{2+}(a q)+2 \mathrm{e}^{-} & E_{\text {zinc }}^{\circ} & =-0.76 \mathrm{~V}
\end{aligned}
$$

Calculating $E_{\text {bromine }}^{\circ}$ :

$$
\begin{aligned}
E_{\text {cell }}^{\circ} & =E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ}=E_{\text {bromine }}^{\circ}-E_{\text {zinc }}^{\circ} \\
E_{\text {bromine }}^{\circ} & =E_{\text {cell }}^{\circ}+E_{\text {zinc }}^{\circ}=1.83 \mathrm{~V}+(-0.76 \mathrm{~V})=1.07 \mathrm{~V}
\end{aligned}
$$

CHECK A good check is to make sure that calculating $E_{\text {bromine }}^{\circ}-E_{\text {zinc }}^{\circ}$ gives $E_{\text {cell }}^{\circ}$ : $1.07 \mathrm{~V}-(-0.76 \mathrm{~V})=1.83 \mathrm{~V}$.
COMMENT Keep in mind that, whichever is the unknown half-cell, reduction is the cathode half-reaction and oxidation is the anode half-reaction. Always subtract $E_{\text {anode }}^{\circ}$ from $E_{\text {cathode }}^{\circ}$ to get $E_{\text {cell }}^{\circ}$.
FOLLOW-UP PROBLEM 21.3 A voltaic cell based on the reaction between aqueous $\mathrm{Br}_{2}$ and vanadium(III) ions has $E_{\text {cell }}^{\circ}=1.39 \mathrm{~V}$ :

$$
\mathrm{Br}_{2}(a q)+2 \mathrm{~V}^{3+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{VO}^{2+}(a q)+4 \mathrm{H}^{+}(a q)+2 \mathrm{Br}^{-}(a q)
$$

What is $E_{\text {vanadium }}^{\circ}$, the standard electrode potential for the reduction of $\mathrm{VO}^{2+}$ to $\mathrm{V}^{3+}$ ?

## Relative Strengths of Oxidizing and Reducing Agents

One of the things we can learn from measuring potentials of voltaic cells is the relative strengths of the oxidizing and reducing agents involved. Three oxidizing agents present in the voltaic cell just discussed are $\mathrm{Cu}^{2+}, \mathrm{H}^{+}$, and $\mathrm{Zn}^{2+}$. We can rank their relative oxidizing strengths by writing each half-reaction as a gain of electrons (reduction), with its corresponding standard electrode potential:

$$
\begin{array}{cl}
\mathrm{Cu}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu}(s) & E^{\circ}=0.34 \mathrm{~V} \\
2 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(g) & E^{\circ}=0.00 \mathrm{~V} \\
\mathrm{Zn}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Zn}(s) & E^{\circ}=-0.76 \mathrm{~V}
\end{array}
$$

The more positive the $E^{\circ}$ value, the more readily the reaction (as written) occurs; thus, $\mathrm{Cu}^{2+}$ gains two electrons more readily than $\mathrm{H}^{+}$, which gains them more readily than $\mathrm{Zn}^{2+}$. In terms of strength as an oxidizing agent, therefore, $\mathrm{Cu}^{2+}>$ $\mathrm{H}^{+}>\mathrm{Zn}^{2+}$. Moreover, this listing also ranks the strengths of the reducing agents: $\mathrm{Zn}>\mathrm{H}_{2}>\mathrm{Cu}$. Notice that this list of half-reactions in order of decreasing halfcell potential shows, from top to bottom, the oxidizing agents (reactants) decreasing in strength and the reducing agents (products) increasing in strength; that is, $\mathrm{Cu}^{2+}$ (top left) is the strongest oxidizing agent, and Zn (bottom right) is the strongest reducing agent.

By combining many pairs of half-cells into voltaic cells, we can create a list of reduction half-reactions and arrange them in decreasing order of standard electrode potential (from most positive to most negative). Such a list, called an emf series or a table of standard electrode potentials, appears in Appendix D, with a few examples in Table 21.2. There are several key points to keep in mind:

- All values are relative to the standard hydrogen (reference) electrode:

$$
2 \mathrm{H}^{+}(a q ; 1 M)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{H}_{2}(g ; 1 \mathrm{~atm}) \quad E_{\text {reference }}^{\circ}=0.00 \mathrm{~V}
$$

- By convention, the half-reactions are written as reductions, which means that only reactants are oxidizing agents and only products are reducing agents.
- The more positive the $E_{\text {half-cell }}^{\circ}$, the more readily the half-reaction occurs.
- Half-reactions are shown with an equilibrium arrow because each can occur as a reduction or an oxidation (that is, take place at the cathode or anode, respectively), depending on the $E_{\text {half-cell }}^{\circ}$ of the other half-reaction.
- As Appendix D (and Table 21.2) is arranged, the strength of the oxidizing agent (reactant) increases going up (bottom to top), and the strength of the reducing agent (product) increases going down (top to bottom).

Table 21.2 Selected Standard Electrode Potentials (298 K)

|  | Half-Reaction |  | $E_{\text {half-cell }}^{\circ} \mathrm{V}$ ) |
| :---: | :---: | :---: | :---: |
|  | $\mathrm{F}_{2}(\mathrm{~g})+2 \mathrm{e}^{-} \rightleftharpoons 2 \mathrm{~F}^{-}(a q)$ |  | +2.87 |
|  | $\mathrm{Cl}_{2}(g)+2 \mathrm{e}^{-} \rightleftharpoons 2 \mathrm{Cl}^{-}(a q)$ |  | +1.36 |
|  | $\int \mathrm{MnO}_{2}(s)+4 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{Mn}^{2+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)$ |  | +1.23 |
|  | $\mathrm{NO}_{3}{ }^{-}(a q)+4 \mathrm{H}^{+}(a q)+3 \mathrm{e}^{-} \rightleftharpoons \mathrm{NO}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)$ |  | +0.96 |
|  | $\mathrm{Ag}^{+}(a q)+\mathrm{e}^{-} \rightleftharpoons \mathrm{Ag}(s)$ |  | +0.80 |
|  |  | $\stackrel{\square}{7}$ | +0.77 |
|  | $\mathrm{O}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)+4 \mathrm{e}^{-} \rightleftharpoons 4 \mathrm{OH}^{-}(a q)$ |  | +0.40 |
|  | $\mathrm{Cu}^{2+}(a q)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{Cu}(s)$ | - | +0.34 |
|  | $2 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{H}_{2}(\mathrm{~g})$ |  | 0.00 |
|  | $\mathrm{N}_{2}(g)+5 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-} \rightleftharpoons \mathrm{N}_{2} \mathrm{H}_{5}{ }^{+}(a q)$ | こ | -0.23 |
|  | $\mathrm{Fe}^{2+}(a q)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{Fe}(s)$ | $\stackrel{\circ}{\square}$ | -0.44 |
|  | $\mathrm{Zn}^{2+}(a q)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{Zn}(\mathrm{s})$ |  | -0.76 |
|  | $2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{H}_{2}(\mathrm{~g})+2 \mathrm{OH}^{-}(a q)$ |  | -0.83 |
|  | $\mathrm{Na}^{+}(a q)+\mathrm{e}^{-} \rightleftharpoons \mathrm{Na}(s)$ |  | -2.71 |
|  | $\mathrm{Li}^{+}(a q)+\mathrm{e}^{-} \rightleftharpoons \mathrm{Li}(s)$ |  | -3.05 |

Thus, $\mathrm{F}_{2}(g)$ is the strongest oxidizing agent (has the largest positive $E^{\circ}$ ), which means $\mathrm{F}^{-}(a q)$ is the weakest reducing agent. Similarly, $\mathrm{Li}^{+}(a q)$ is the weakest oxidizing agent (has the most negative $E^{\circ}$ ), which means $\operatorname{Li}(s)$ is the strongest reducing agent. (You may have noticed an analogy to conjugate acid-base pairs: a strong acid forms a weak conjugate base, and vice versa, just as a strong oxidizing agent forms a weak reducing agent, and vice versa.)

If you forget the ranking in the table, just rely on your chemical knowledge of the elements. You know that $F_{2}$ is very electronegative and typically occurs as $\mathrm{F}^{-}$. It is easily reduced (gains electrons), so it must be a strong oxidizing agent (high, positive $E^{\circ}$ ). Similarly, Li metal has a low ionization energy and typically occurs as $\mathrm{Li}^{+}$. Therefore, it is easily oxidized (loses electrons), so it must be a strong reducing agent (low, negative $E^{\circ}$ ).
Writing Spontaneous Redox Reactions Appendix D can be used to write spontaneous redox reactions, which is useful for constructing voltaic cells.

Every redox reaction is the sum of two half-reactions, so there is a reducing agent and an oxidizing agent on each side. In the zinc-copper reaction, for
instance, Zn and Cu are the reducing agents, and $\mathrm{Cu}^{2+}$ and $\mathrm{Zn}^{2+}$ are the oxidizing agents. The stronger oxidizing and reducing agents react spontaneously to form the weaker oxidizing and reducing agents:

Here, too, note the similarity to acid-base chemistry. The stronger acid and base spontaneously form the weaker base and acid, respectively. The members of a conjugate acid-base pair differ by a proton: the acid has the proton and the base does not. The members of a redox pair, or redox couple, such as Zn and $\mathrm{Zn}^{2+}$, differ by one or more electrons: the reduced form $(\mathrm{Zn})$ has the electrons and the oxidized form $\left(\mathrm{Zn}^{2+}\right)$ does not. In acid-base reactions, we compare acid and base strength using $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ values. In redox reactions, we compare oxidizing and reducing strength using $E^{\circ}$ values.

Based on the order of the $E^{\circ}$ values in Appendix D , the stronger oxidizing agent (species on the left) has a half-reaction with a larger (more positive or less negative) $E^{\circ}$ value, and the stronger reducing agent (species on the right) has a half-reaction with a smaller (less positive or more negative) $E^{\circ}$ value. Therefore, a spontaneous reaction $\left(E_{\text {cell }}^{\circ}>0\right)$ will occur between an oxidizing agent and any reducing agent that lies below it in the list. For instance, Zn (right) lies below $\mathrm{Cu}^{2+}$ (left), and $\mathrm{Cu}^{2+}$ and Zn react spontaneously. In other words, for a spontaneous reaction to occur, the half-reaction higher in the list proceeds at the cathode as written, and the half-reaction lower in the list proceeds at the anode in reverse. This pairing ensures that the stronger oxidizing agent (higher on the left) and stronger reducing agent (lower on the right) will be the reactants.

However, if we know the electrode potentials, we can write a spontaneous redox reaction even if Appendix $D$ is not available. Let's choose a pair of halfreactions from the appendix and, whonterering theirfentivepositusin the list, use them to write a spontaneous redox reaction:

$$
\begin{aligned}
\mathrm{Ag}^{+}(a q)+\mathrm{e}^{-} \longrightarrow \mathrm{Ag}(s) & E_{\text {silver }}^{\circ}=0.80 \mathrm{~V} \\
\mathrm{Sn}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Sn}(s) & E_{\text {tin }}^{\circ}=-0.14 \mathrm{~V}
\end{aligned}
$$

There are two steps involved:

1. Reverse one of the half-reactions into an oxidation step such that the difference of the electrode potentials (cathode minus anode) gives a positive $E_{\text {cell }}^{\circ}$. Note that when we reverse the half-reaction, we need not reverse the sign of $E_{\text {half-cell }}^{\circ}$ because the minus sign in Equation $21.3\left(E_{\text {cell }}^{\circ}=E_{\text {cathode }}^{\circ}-E_{\text {anode }}^{\circ}\right)$ will do that.
2. Add the rearranged half-reactions to obtain a balanced overall equation. Be sure to multiply by coefficients so that $\mathrm{e}^{-}$lost equals $\mathrm{e}^{-}$gained and to cancel species common to both sides.
(You may be tempted in this particular case to add the two half-reactions as written, because you obtain a positive $E_{\text {cell }}^{\circ}$, but you would then have two oxidizing agents forming two reducing agents, which cannot occur.)

We want to pair the stronger oxidizing and reducing agents as reactants. The larger (more positive) $E^{\circ}$ value for the silver half-reaction means that $\mathrm{Ag}^{+}$is a stronger oxidizing agent (gains electrons more readily) than $\mathrm{Sn}^{2+}$, and the smaller (more negative) $E^{\circ}$ value for the tin half-reaction means that Sn is a stronger reducing agent (loses electrons more readily) than Ag . Therefore, we reverse the tin half-reaction (but not the sign of $E_{\text {tin }}^{\circ}$ ):

$$
\mathrm{Sn}(s) \longrightarrow \mathrm{Sn}^{2+}(a q)+2 \mathrm{e}^{-} \quad E_{\mathrm{tin}}^{\circ}=-0.14 \mathrm{~V}
$$

Subtracting $E_{\text {half-cell }}^{\circ}$ of the tin half-reaction (anode, oxidation) from $E_{\text {half-cell }}^{\circ}$ of the silver half-reaction (cathode, reduction) gives a positive $E_{\text {cell }}^{\circ}$; that is, $0.80 \mathrm{~V}-(-0.14 \mathrm{~V})=0.94 \mathrm{~V}$.

With the half-reactions written in the correct direction, we must next make sure that the number of electrons lost in the oxidation equals the number gained in the reduction. In this case, we double the silver (reduction) half-reaction. Adding the half-reactions and applying Equation 21.3 gives the balanced equation and $E_{\text {cell }}$ :

$$
\begin{array}{rlrl}
2 \mathrm{Ag}^{+}(a q)+2 \mathrm{e}^{-} & E_{\text {silver }}^{\circ}=0.80 \mathrm{~V} & \text { [reduction] } \\
\mathrm{Sn}(s) \longrightarrow \mathrm{Ag}^{\circ} \longrightarrow(s) & \mathrm{Sn}^{2+}(a q)+2 \mathrm{e}^{-} & E_{\text {tin }}^{\circ}=-0.14 \mathrm{~V} & \text { [oxidation] } \\
\hline \mathrm{Sn}(s)+2 \mathrm{Ag}^{+}(a q) \longrightarrow \mathrm{Sn}^{2+}(a q)+2 \mathrm{Ag}(s) & E_{\text {cell }}^{\circ}=E_{\text {silver }}^{\circ}-E_{\text {tin }}^{\circ}=0.94 \mathrm{~V}
\end{array}
$$

With the reaction spontaneous as written, the stronger oxidizing and reducing agents are reactants, which confirms that Sn is a stronger reducing agent than Ag , and $\mathrm{Ag}^{+}$is a stronger oxidizing agent than $\mathrm{Sn}^{2+}$.

A very important point to note is that, when we doubled the coefficients of the silver half-reaction to balance the number of electrons, we did not double its $E^{\circ}$ value-it remained 0.80 V . That is, changing the balancing coefficients of a half-reaction does not change its $E^{\circ}$ value. The reason is that a standard electrode potential is an intensive property, one that does not depend on the amount of substance present. The potential is the ratio of energy to charge. When we change the coefficients, thus changing the amount of substance, the energy and the charge change proportionately, so their ratio stays the same. (Recall that density, which is also an intensive property, does not change with the amount of substance because the mass and the volume change proportionately.)

SAMPLE PROBLEM 21.4 Writing Spontaneous Redox Reactions and Ranking Oxidizing and Reducing Agents by Strength
PROBLEM (a) Combine the following three half-reactions into three balanced equations (A, B , and C ) for spontaneous reactions, and calculate $E_{\text {cell }}^{\circ}$ for each. (b) Rank the relative strengths of the oxidizing and reducing agents.
(1) $\mathrm{NO}_{3}{ }^{-}(a q)+4 \mathrm{H}^{+}(a q)+3 \mathrm{e}^{-} \longrightarrow \mathrm{NO}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \quad E^{\circ}=0.96 \mathrm{~V}$
(2) $\mathrm{N}_{2}(g)+5 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-} \longrightarrow \mathrm{N}_{2} \mathrm{H}_{5}^{+}(a q) \quad E^{\circ}=-0.23 \mathrm{~V}$
(3) $\mathrm{MnO}_{2}(s)+4 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Mn}^{2+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \quad E^{\circ}=1.23 \mathrm{~V}$

PLAN (a) To write the redox equations, we combine the possible pairs of half-reactions: (1) and (2), (1) and (3), and (2) and (3). They are all written as reductions, so the oxidizing agents appear as reactants and the reducing agents appear as products. In each pair, we reverse the reduction half-reaction that has the smaller (less positive or more negative) $E^{\circ}$ value to an oxidation to obtain a positive $E_{\text {cell. }}^{\circ}$. We make $\mathrm{e}^{-}$lost equal $\mathrm{e}^{-}$gained, without changing the magnitude of the $E^{\circ}$ value, add the half-reactions together, and then apply Equation 21.3 to find $E_{\text {cell. }}^{\circ}$ (b) Because each reaction is spontaneous as written, the stronger oxidizing and reducing agents are the reactants. To obtain the overall ranking, we first rank the relative strengths within each equation and then compare them.
SOLUTION (a) Combining half-reactions (1) and (2) gives equation (A). The $E^{\circ}$ value for half-reaction (1) is larger (more positive) than that for (2), so we reverse (2) to obtain a positive $E_{\text {cell }}^{\circ}$ :

$$
\begin{array}{ll}
(1) \mathrm{NO}_{3}^{-}(a q)+4 \mathrm{H}^{+}(a q)+3 \mathrm{e}^{-} \longrightarrow \mathrm{NO}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) & E^{\circ}=0.96 \mathrm{~V} \\
\text { (rev 2) } & \mathrm{N}_{2} \mathrm{H}_{5}^{+}(a q) \longrightarrow \mathrm{N}_{2}(g)+5 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-}
\end{array} E^{\circ}=-0.23 \mathrm{~V} . l
$$

To make $\mathrm{e}^{-}$lost equal $\mathrm{e}^{-}$gained, we multiply (1) by four and the reversed (2) by three; then add half-reactions and cancel appropriate numbers of common species $\left(\mathrm{H}^{+}\right.$and $\left.\mathrm{e}^{-}\right)$:

$$
\begin{aligned}
& 4 \mathrm{NO}_{3}^{-}(a q)+16 \mathrm{H}^{+}(a q)+12 \mathrm{e}^{-} \longrightarrow 4 \mathrm{NO}(g)+8 \mathrm{H}_{2} \mathrm{O}(l) \\
& 3 \mathrm{~N}_{2} \mathrm{H}_{5}^{+}(a q) \longrightarrow 3 \mathrm{~N}_{2}(g)+15 \mathrm{H}^{+}(a q)+12 \mathrm{e}^{-} E^{\circ}=0.96 \mathrm{~V} \\
& E^{\circ}=-0.23 \mathrm{~V}
\end{aligned}
$$

(A) $3 \mathrm{~N}_{2} \mathrm{H}_{5}^{+}(a q)+4 \mathrm{NO}_{3}^{-}(a q)+\mathrm{H}^{+}(a q) \longrightarrow 3 \mathrm{~N}_{2}(g)+4 \mathrm{NO}(g)+8 \mathrm{H}_{2} \mathrm{O}(l)$

$$
E_{\mathrm{cell}}^{\circ}=0.96 \mathrm{~V}-(-0.23 \mathrm{~V})=1.19 \mathrm{~V}
$$

Combining half-reaction (1) and half-reaction (3) gives equation (B). Half-reaction (1) must be reversed:
(rev 1) $\quad \mathrm{NO}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{NO}_{3}^{-}(a q)+4 \mathrm{H}^{+}(a q)+3 \mathrm{e}^{-} \quad E^{\circ}=0.96 \mathrm{~V}$
(3) $\mathrm{MnO}_{2}(s)+4 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Mn}^{2+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \quad E^{\circ}=1.23 \mathrm{~V}$

We multiply reversed (1) by two and (3) by three, then add and cancel:

$$
\begin{array}{rlr}
2 \mathrm{NO}(g)+4 \mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow 2 \mathrm{NO}_{3}^{-}(a q)+8 \mathrm{H}^{+}(a q)+6 \mathrm{e}^{-} & E^{\circ}=0.96 \mathrm{~V} \\
3 \mathrm{MnO}_{2}(s)+12 \mathrm{H}^{+}(a q)+6 \mathrm{e}^{-} \longrightarrow 3 \mathrm{Mn}^{2+}(a q)+6 \mathrm{H}_{2} \mathrm{O}(l) & E^{\circ}=1.23 \mathrm{~V}
\end{array}
$$

(B) $3 \mathrm{MnO}_{2}(s)+4 \mathrm{H}^{+}(a q)+2 \mathrm{NO}(g) \longrightarrow 3 \mathrm{Mn}^{2+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{NO}_{3}{ }^{-}(a q)$

$$
E_{\mathrm{cell}}^{\circ}=1.23 \mathrm{~V}-0.96 \mathrm{~V}=0.27 \mathrm{~V}
$$

Combining half-reaction (2) and half-reaction (3) gives equation (C). Half-reaction (2) must be reversed:
(rev 2)
$\mathrm{N}_{2} \mathrm{H}_{5}{ }^{+}(a q) \longrightarrow \mathrm{N}_{2}(g)+5 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-}$
$E^{\circ}=-0.23 \mathrm{~V}$
(3) $\mathrm{MnO}_{2}(s)+4 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Mn}^{2+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)$
$E^{\circ}=1.23 \mathrm{~V}$

We multiply reaction (3) by two, add the half-reactions, and cancel:

$$
\begin{aligned}
& \mathrm{N}_{2} \mathrm{H}_{5}^{+}(a q) \mathrm{N}_{2}(g)+5 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-} \\
& 2 \mathrm{MnO}_{2}(s)+8 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-} \longrightarrow 2 \mathrm{Mn}^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l) E^{\circ}=1.23 \mathrm{~V} \\
& \hline
\end{aligned}
$$

(C) $\mathrm{N}_{2} \mathrm{H}_{5}{ }^{+}(a q)+2 \mathrm{MnO}_{2}(s)+3 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{N}_{2}(g)+2 \mathrm{Mn}^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)$

$$
E_{\mathrm{cell}}^{\circ}=1.23 \mathrm{~V}-(-0.23 \mathrm{~V})=1.46 \mathrm{~V}
$$

(b) Ranking the oxidizing and reducing agents within each equation:

Equation (A): Oxidizing agents: $\mathrm{NO}_{3}{ }^{-}>\mathrm{N}_{2} \quad$ Reducing agents: $\mathrm{N}_{2} \mathrm{H}_{5}{ }^{+}>\mathrm{NO}$
Equation (B): Oxidizing agents: $\mathrm{MnO}_{2}>\mathrm{NO}_{3}{ }^{-} \quad$ Reducing agents: $\mathrm{NO}>\mathrm{Mn}^{2+}$
Equation (C): Oxidizing agents: $\mathrm{MnO}_{2}>\mathrm{N}_{2} \quad$ Reducing agents: $\mathrm{N}_{2} \mathrm{H}_{5}{ }^{+}>\mathrm{Mn}^{2+}$
Determining the overall ranking of oxidizing and reducing agents. Comparing the relative strengths from the three balanced equations gives

> Oxidizing agents: $\mathrm{MnO}_{2}>\mathrm{NO}_{3}^{-}>\mathrm{N}_{2}$
> Reducing agents: $\mathrm{N}_{2} \mathrm{H}_{5}^{+}>\mathrm{NO}>\mathrm{Mn}^{2+}$

CHECK As always, check that atoms and charge balance on each side of the equation. A good way to check the ranking and equations is to list the given half-reactions in order of decreasing $E^{\circ}$ value:

$$
\begin{array}{cl}
\mathrm{MnO}_{2}(s)+4 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Mn}^{2+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) & E^{\circ}=1.23 \mathrm{~V} \\
\mathrm{NO}_{3}^{-}(a q)+4 \mathrm{H}^{+}(a q)+3 \mathrm{e}^{-} \longrightarrow \mathrm{NO}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) & E^{\circ}=0.96 \mathrm{~V} \\
\mathrm{~N}_{2}(g)+5 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-} \longrightarrow \mathrm{N}_{2} \mathrm{H}_{5}^{+}(a q) & E^{\circ}=-0.23 \mathrm{~V}
\end{array}
$$

Then the oxidizing agents (reactants) decrease in strength going down the list, so the reducing agents (products) decrease in strength going up. Moreover, each of the three spontaneous reactions ( $\mathrm{A}, \mathrm{B}$, and C ) should combine a reactant with a product that is lower down on this list.

FOLLOW-UP PROBLEM 21.4 Is the following reaction spontaneous as written?

$$
3 \mathrm{Fe}^{2+}(a q) \longrightarrow \mathrm{Fe}(s)+2 \mathrm{Fe}^{3+}(a q)
$$

If not, write the equation for the spontaneous reaction, calculate $E_{\text {cell }}^{\circ}$, and rank the three species of iron in order of decreasing reducing strength.

Relative Reactivities of Metals In Chapter 4, we discussed the activity series of the metals (see Figure 4.21 , p. 171), which ranks metals by their ability to "displace" one another from aqueous solution. Now you'll see why this displacement occurs, as well as why many, but not all, metals react with acid to form $\mathrm{H}_{2}$, and why a few metals form $\mathrm{H}_{2}$ even in water.

1. Metals that can displace $H_{2}$ from acid. The standard hydrogen halfreaction represents the reduction of $\mathrm{H}^{+}$ions from an acid to $\mathrm{H}_{2}$ :

$$
2 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(g) \quad E^{\circ}=0.00 \mathrm{~V}
$$

To see which metals reduce $\mathrm{H}^{+}$(referred to as "displacing $\mathrm{H}_{2}$ ") from acids, choose a metal, write its half-reaction as an oxidation, combine this half-reaction with the hydrogen half-reaction, and see if $E_{\text {cell }}^{\circ}$ is positive. What you find is that the metals Li through Pb , those that lie below the standard hydrogen (reference) half-reaction in Appendix D , give a positive $E_{\text {cell }}^{\circ}$ when reducing $\mathrm{H}^{+}$. Iron, for example, reduces $\mathrm{H}^{+}$from an acid to $\mathrm{H}_{2}$ :

$$
\begin{array}{rlrl}
\mathrm{Fe}(s) & \longrightarrow \mathrm{Fe}^{2+}(a q)+2 \mathrm{e}^{-} & E^{\circ} & =-0.44 \mathrm{~V} \\
\mathrm{E}^{+} & =0.00 \mathrm{~V} \quad & \text { [anode; oxidation] } \\
\text { [cathode; reduction] } \\
2 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(g) & \mathrm{H}_{2}(g)+\mathrm{Fe}^{2+}(a q) & E_{\text {cell }}^{\circ}=0.00 \mathrm{~V}-(-0.44 \mathrm{~V})=0.44 \mathrm{~V}
\end{array}
$$

The lower the metal in the list, the stronger it is as a reducing agent; therefore, the more positive its half-cell potential when the half-reaction is reversed, and the higher the $E_{\text {cell }}^{\circ}$ for its reduction of $\mathrm{H}^{+}$to $\mathrm{H}_{2}$. If $E_{\text {cell }}^{\circ}$ for the reduction of $\mathrm{H}^{+}$is more positive for metal $A$ than it is for metal $B$, metal $A$ is a stronger reducing agent than metal $B$ and a more active metal.
2. Metals that cannot displace $\mathrm{H}_{2}$ from acid. Metals that are above the standard hydrogen (reference) half-reaction cannot reduce $\mathrm{H}^{+}$from acids. When we reverse the metal half-reaction, the $E_{\text {cell }}^{\circ}$ is negative, so the reaction does not occur. For example, the coinage metals-copper, silver, and gold, which are in Group $1 \mathrm{~B}(11)$ —are not strong enough reducing agents to reduce $\mathrm{H}^{+}$from acids:

The higher the metal in the list, the more negative is its $E_{\text {cell }}^{\circ}$ for the reduction of $\mathrm{H}^{+}$to $\mathrm{H}_{2}$, the lower is its reducing strength, and the less active it is. Thus, gold is less active than silver, which is less active than copper.
3. Metals that can displace $\mathrm{H}_{2}$ from water. Metals active enough to reduce $\mathrm{H}_{2} \mathrm{O}$ lie below that half-reaction:

$$
2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(g)+2 \mathrm{OH}^{-}(a q) \quad E=-0.42 \mathrm{~V}
$$

(The value shown here is the nonstandard electrode potential because, in pure water, $\left[\mathrm{OH}^{-}\right]$is $1.0 \times 10^{-7} \mathrm{M}$, not the standard-state value of $1 M$.) For example, consider the reaction of sodium in water (with the $\mathrm{Na}^{+} / \mathrm{Na}$ half-reaction reversed and doubled):

$$
\begin{aligned}
& 2 \mathrm{Na}(s) \longrightarrow 2 \mathrm{Na}^{+}(a q)+2 \mathrm{e}^{-} E^{\circ}=-2.71 \mathrm{~V} \\
& 2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(g)+2 \mathrm{OH}^{-}(a q) \quad \quad \text { [anode; oxidation] } \\
& E=-0.42 \mathrm{~V} \text { [cathode; reduction] } \\
& \hline 2 \mathrm{Na}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{Na}^{+}(a q)+\mathrm{H}_{2}(g)+2 \mathrm{OH}^{-}(a q) \\
& E_{\text {cell }}=-0.42 \mathrm{~V}-(-2.71 \mathrm{~V})=2.29 \mathrm{~V}
\end{aligned}
$$

The alkali metals [Group $1 \mathrm{~A}(1)$ ] and the larger alkaline earth metals [Group $2 \mathrm{~A}(2)$ ] can reduce water, or displace $\mathrm{H}_{2}$ from $\mathrm{H}_{2} \mathrm{O}$ (Figure 21.9).
4. Metals that can displace other metals from solution. We can also predict whether one metal can reduce the aqueous ion of another metal. Any metal that is lower in the list in Appendix D can reduce the ion of a metal that is higher up, and thus displace that metal from solution. For example, zinc can displace iron from solution:

| $\mathrm{Zn}(s)$ | $\longrightarrow \mathrm{Zn}^{2+}(a q)+2 \mathrm{e}^{-}$ | $E^{\circ}$ | $=-0.76 \mathrm{~V}$ |
| ---: | :--- | ---: | :--- |
|  | $E^{\circ}$ | $=-0.44 \mathrm{~V}$ | [anode; oxidation] |
| $\mathrm{Fe}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Fe}(s)$ | $\mathrm{Zn}^{2+}(a q)+\mathrm{Fe}(s)$ | $E_{\text {cell }}^{\circ}$ | $=-0.44 \mathrm{~V}-(-0.76 \mathrm{~V})=0.32 \mathrm{~V}$ |

This particular reaction has tremendous economic importance in protecting iron from rusting, as you'll see shortly. The reducing power of metals has other, more personal, consequences, as the margin note points out.

## Section Summary

The output of a cell is called the cell potential ( $E_{\text {cell }}$ ) and is measured in volts ( $1 \mathrm{~V}=1 \mathrm{~J} / \mathrm{C}$ ). - When all substances are in their standard states, the output is the standard cell potential $\left(E_{\text {cell }}^{\circ}\right)$. $E_{\text {cell }}^{\circ}>0$ for a spontaneous reaction at standard-state conditions. - By convention, a standard electrode potential ( $E_{\text {half-cell }}^{\circ}$ ) refers to the reduction half-reaction. $E_{\text {cell }}^{\circ}$ equals $E_{\text {half-cell }}^{\circ}$ of the cathode minus $E_{\text {half-cell }}^{\circ}$ of the anode. - Using a standard hydrogen (reference) electrode ( $E_{\text {reference }}^{\circ}=0 \mathrm{~V}$ ), $E_{\text {half-cell }}^{\circ}$ values can be measured and used to rank oxidizing (or reducing) agents (see Appendix D). - Spontaneous redox reactions combine stronger oxidizing and reducing agents to form weaker ones. - A metal can reduce another species $\left(\mathrm{H}^{+}, \mathrm{H}_{2} \mathrm{O}\right.$, or an ion of another metal) if $E_{\text {cell }}^{\circ}$ for the reaction is positive.

### 21.4 FREE ENERGY AND ELECTRICAL WORK

In Chapter 20, we discussed the relationship of useful work, free energy, and the equilibrium constant. In this section, we examine this relationship in the context of electrochemical cells and see the effect of concentration on cell potential.

## Standard Cell Potential and the Equilibrium Constant

As you know from Section 20.3, a spontaneous reaction has a negative free energy change $(\Delta G<0)$, and you've just seen that a spontaneous electrochemical reaction has a positive cell potential $\left(E_{\text {cell }}>0\right)$. Note that the signs of $\Delta G$ and $E_{\text {cell }}$ are opposite for a spontaneous reaction. Ahes twaindicationsofspontaneif are proportional to each other:

$$
\Delta G \propto-E_{\text {cell }}
$$

Let's determine this proportionality constant by focusing on the electrical work done ( $w$, in joules), which is the product of the potential ( $E_{\text {cell }}$, in volts) and the amount of charge that flows (in coulombs). The value used for $E_{\text {cell }}$ is measured with no current flowing and, therefore, no energy lost to heating the cell. Thus, $E_{\text {cell }}$ is the maximum voltage possible for the cell, and the work is the maximum work possible $\left(w_{\max }\right)$. For work done by the cell on the surroundings, this quantity is negative:*

$$
w_{\max }=-E_{\text {cell }} \times \text { charge }
$$

Equation 20.9, p. 902, shows that the maximum work done on the surroundings is $\Delta G$ :

$$
w_{\max }=-E_{\text {cell }} \times \text { charge }=\Delta G \quad \text { and so } \quad \Delta G=-E_{\text {cell }} \times \text { charge }
$$

The charge that flows through the cell equals the number of moles of electrons ( $n$ ) transferred times the charge of 1 mol of electrons (symbol $F$ ):

$$
\text { Charge }=\text { moles of } \mathrm{e}^{-} \times \frac{\text { charge }}{\text { mol e }^{-}} \quad \text { or } \quad \text { charge }=n F
$$

The charge of 1 mol of electrons is the Faraday constant $(\boldsymbol{F})$, named in honor of Michael Faraday, the $19^{\text {th }}$-century British scientist who pioneered the study of electrochemistry:

$$
F=\frac{96,485 \mathrm{C}}{\mathrm{~mol} \mathrm{e}^{-}}
$$

[^33] Have you ever felt a jolt of pain when biting down with a filled tooth on a scrap of foil left on a piece of food? Here's the reason. The aluminum foil acts as an active anode ( $E^{\circ}$ of $\mathrm{Al}=-1.66 \mathrm{~V}$ ), saliva as the electrolyte, and the filling (usually a silver/tin/mercury alloy) as an inactive cathode. $\mathrm{O}_{2}$ is reduced to water, and the short circuit between the foil in contact with the filling creates a current that is sensed by the nerve of the tooth.

Because $1 \mathrm{~V}=1 \mathrm{~J} / \mathrm{C}$, we have $1 \mathrm{C}=1 \mathrm{~J} / \mathrm{V}$, and

$$
\begin{equation*}
F=9.65 \times 10^{4} \frac{\mathrm{~J}}{\mathrm{~V} \cdot \mathrm{~mol} \mathrm{e}^{-}} \quad(3 \mathrm{sf}) \tag{21.4}
\end{equation*}
$$

Substituting for charge, the proportionality constant is $n F$ :

$$
\begin{equation*}
\Delta G=-n F E_{\mathrm{cell}} \tag{21.5}
\end{equation*}
$$

When all of the components are in their standard states, we have

$$
\begin{equation*}
\Delta G^{\circ}=-n F E_{\mathrm{cell}}^{\circ} \tag{21.6}
\end{equation*}
$$

Using this relationship, we can relate the standard cell potential to the equilibrium constant of the redox reaction. Recall from Equation 20.12 that

$$
\Delta G^{\circ}=-R T \ln K
$$

Substituting for $\Delta G^{\circ}$ from Equation 21.6 gives

$$
-n F E_{\text {cell }}^{\circ}=-R T \ln K
$$

Solving for $E_{\text {cell }}^{\circ}$ gives

$$
\begin{equation*}
E_{\mathrm{cell}}^{\circ}=\frac{R T}{n F} \ln K \tag{21.7}
\end{equation*}
$$

Figure 21.10 summarizes the interconnections among the standard free energy change, the equilibrium constant, and the standard cell potential. Notice that, even though these relationships hold under standard-state conditions, they are still extremely useful. Recall from Chapter 20 that determining $K$ required that we know $\Delta G^{\circ}$, either from $\Delta H^{\circ}$ and $\Delta S^{\circ}$ values or from $\Delta G_{\mathrm{f}}^{\circ}$ values. Now, for redox reactions, we have a direct experimental method for determining $K$ and $\Delta G^{\circ}$ : measuring $E_{\text {cell }}^{\circ}$.
Apago PDF Enhancer

It is common practice to simplify Equation 21.7 in calculations by

- Substituting the known value of $8.314 \mathrm{~J} /(\mathrm{mol} \mathrm{rxn} \cdot \mathrm{K})$ for the constant $R$
- Substituting the known value of $9.65 \times 10^{4} \mathrm{~J} /\left(\mathrm{V} \cdot \mathrm{mol} \mathrm{e}^{-}\right)$for the constant $F$
- Substituting the standard temperature of 298.15 K for $T$, but keeping in mind that the cell can run at other temperatures.
- Multiplying by 2.303 to convert from natural to common (base-10) logarithms. This conversion shows that a 10 -fold change in $K$ makes $E_{\text {cell }}^{\circ}$ change by 1 .

Thus, when $n$ moles of $\mathrm{e}^{-}$are transferred per mole of reaction in the balanced equation, this simplified relation between $E_{\text {cell }}^{\circ}$ and $K$ gives

$$
E_{\text {cell }}^{\circ}=\frac{R T}{n F} \ln K=2.303 \frac{R T}{n F} \log K=2.303 \times \frac{8.314 \frac{\mathrm{~J}}{\mathrm{~mol} \mathrm{~m} \mathrm{\times n} \cdot \mathrm{~K}} \times 298.15 \mathrm{~K}}{\frac{n \mathrm{~mole} \mathrm{e}^{-}}{\mathrm{mol} \mathrm{rxn}}\left(9.65 \times 10^{4} \frac{\mathrm{~J}}{\mathrm{~V} \cdot \mathrm{~mol} \mathrm{e}^{-}}\right)} \log K
$$

And, we have

$$
\begin{equation*}
E_{\mathrm{cell}}^{\circ}=\frac{0.0592 \mathrm{~V}}{n} \log K \quad \text { or } \quad \log K=\frac{n E_{\mathrm{cell}}^{\circ}}{0.0592 \mathrm{~V}} \quad(\text { at } 298.15 \mathrm{~K}) \tag{21.8}
\end{equation*}
$$

## SAMPLE PROBLEM 21.5 Calculating $K$ and $\Delta G^{\circ}$ from $E_{\text {cell }}^{\circ}$

PROBLEM Lead can displace silver from solution:

$$
\mathrm{Pb}(s)+2 \mathrm{Ag}^{+}(a q) \longrightarrow \mathrm{Pb}^{2+}(a q)+2 \mathrm{Ag}(s)
$$

As a consequence, silver is a valuable byproduct in the industrial extraction of lead from its ore. Calculate $K$ and $\Delta G^{\circ}$ at 298.15 K for this reaction.
PLAN We divide the spontaneous redox equation into the half-reactions and use values from Appendix D to calculate $E_{\text {cell. }}^{\circ}$ Then, we substitute this result into Equation 21.8 to find $K$ and into Equation 21.6 to find $\Delta G^{\circ}$.
SOLUTION Writing the half-reactions with their $E^{\circ}$ values:
(1) $\mathrm{Ag}^{+}(a q)+\mathrm{e}^{-} \longrightarrow \operatorname{Ag}(s) \quad E^{\circ}=0.80 \mathrm{~V}$
(2) $\mathrm{Pb}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Pb}(s) \quad E^{\circ}=-0.13 \mathrm{~V}$

Calculating $E_{\text {cell }}^{\circ}$ : We double (1), reverse (2), add the half-reactions, and subtract $E_{\text {lead }}^{\circ}$ from $E_{\text {silver }}^{\circ}$ :

$$
\begin{array}{rlrl}
2 \mathrm{Ag}^{+}(a q)+2 \mathrm{e}^{-} & \longrightarrow 2 \mathrm{Ag}(s) & E^{\circ} & =0.80 \mathrm{~V} \\
\mathrm{~Pb}(s) & \longrightarrow \mathrm{Pb}^{2+}(a q)+2 \mathrm{e}^{-} & E^{\circ}=-0.13 \mathrm{~V} \\
\hline \mathrm{~Pb}(s)+2 \mathrm{Ag}^{+}(a q) & \longrightarrow \mathrm{Pb}^{2+}(a q)+2 \mathrm{Ag}(s) & E_{\text {cell }}^{\circ}=0.80 \mathrm{~V}-(-0.13 \mathrm{~V})=0.93 \mathrm{~V}
\end{array}
$$

Calculating $K$ with Equations 21.7 and 21.8:

$$
E_{\mathrm{cell}}^{\circ}=\frac{R T}{n F} \ln K=2.303 \frac{R T}{n F} \log K
$$

The adjusted half-reactions show that 2 mol of $\mathrm{e}^{-}$are transferred per mole of reaction as written, so $n=2$. Then, performing the substitutions for $R$ and $F$ that we just discussed with the cell running at $25^{\circ} \mathrm{C}(298.15 \mathrm{~K})$, we have

$$
E_{\mathrm{cell}}^{\circ}=\frac{0.0592 \mathrm{~V}}{2} \log K=0.93 \mathrm{~V}
$$

So, $\quad \log K=\frac{0.93 \mathrm{~V} \times 2}{0.0592 \mathrm{~V}}=31.42 \quad$ and $\quad K=2.6 \times 10^{31}$
Calculating $\Delta G^{\circ}$ (Equation 21.6):

$$
\Delta G^{\circ}=-n F E_{\mathrm{cell}}^{\circ}=-\frac{2 \mathrm{~mol} \mathrm{e}^{-}}{\mathrm{mol} \mathrm{rxn}} \times \frac{96.5 \mathrm{~kJ}}{\mathrm{~V} \cdot \mathrm{~mol} \mathrm{e}^{-}} \times 0.93 \mathrm{~V}=-1.8 \times 10^{2} \mathrm{~kJ} / \mathrm{mol} \mathrm{rxn}
$$

CHECK The three variables are consistent with the reaction being spontaneous at standardstate conditions: $E_{\text {cell }}^{\circ}>0, \Delta G^{\circ}<0$, and $K>1$. Be sure to round and check the order of magnitude: in the $\Delta G^{\circ}$ calculation, for instance, $\Delta G^{\circ} \approx-2 \times 100 \times 1=-200$, so the overall math seems right. Another check would be to obtain $\Delta G^{\circ}$ directly from its relation with $K$ :

$$
\begin{aligned}
\Delta G^{\circ} & =-R T \ln K=-8.314 \mathrm{~J} / \mathrm{mol} \mathrm{rxn} \cdot \mathrm{~K} \times 298.15 \mathrm{~K} \times \ln \left(2.6 \times 10^{31}\right) \\
& =-1.8 \times 10^{5} \mathrm{~J} / \mathrm{mol} \mathrm{rxn}=-1.8 \times 10^{2} \mathrm{~kJ} / \mathrm{mol} \mathrm{rxn}
\end{aligned}
$$

FOLLOW-UP PROBLEM 21.5 When cadmium metal reduces $\mathrm{Cu}^{2+}$ in solution, $\mathrm{Cd}^{2+}$ forms in addition to copper metal. Given that $\Delta G^{\circ}=-143 \mathrm{~kJ} / \mathrm{mol}$ rxn, calculate $K$ at $25^{\circ} \mathrm{C}$. What is $E_{\mathrm{cell}}^{\circ}$ of a voltaic cell that uses this reaction?

This great German physical chemist was only 25 years old when he developed the equation for the relationship between cell voltage and concentration. His career, which culminated in the Nobel Prize in chemistry in 1920, included formulating the third law of thermodynamics, establishing the principle of the solubility product, and contributing key ideas to photochemistry and the Haber process. He is shown here in later years making a point to a few of his celebrated colleagues: from left to right, Nernst, Albert Einstein, Max Planck, Robert Millikan, and Max von Laue.

## The Effect of Concentration on Cell Potential

So far, we've considered cells with all components in their standard states and found standard cell potential ( $E_{\text {cell }}^{\circ}$ ) from standard half-cell potentials ( $E_{\text {half-cell }}^{\circ}$ ). However, most cells do not start with all components in their standard states, and even if they did, the concentrations change after a few moments of operation. Moreover, in all practical voltaic cells, such as batteries, reactant concentrations are far from standard-state values. Clearly, we must be able to determine $E_{\text {cell }}$, the cell potential under nonstandard conditions.

To do so, let's derive an expression for the relation between cell potential and concentration based on the relation between free energy and concentration. Recall from Chapter 20 (Equation 20.13) that $\Delta G$ equals $\Delta G^{\circ}$ (the free energy change when the system moves from standard-state concentrations to equilibrium) plus $R T \ln Q$ (the free energy change when the system moves from nonstandard-state to standard-state concentrations):

$$
\Delta G=\Delta G^{\circ}+R T \ln Q
$$

$\Delta G$ is related to $E_{\text {cell }}$ and $\Delta G^{\circ}$ to $E_{\text {cell }}^{\circ}$ (Equations 21.5 and 21.6), so we substitute for them and get

$$
-n F E_{\text {cell }}=-n F E_{\text {cell }}^{\circ}+R T \ln Q
$$

Dividing both sides by $-n F$, we obtain the Nernst equation, developed by the German chemist Walther Hermann Nernst in 1889:

$$
\begin{equation*}
E_{\mathrm{cell}}=E_{\mathrm{cell}}^{\circ}-\frac{R T}{n F} \ln Q \tag{21.9}
\end{equation*}
$$

The Nernst equation says that a cell potential under any conditions depends on the potential at standard-state concentrations and a term for the potential at nenstandard-state concentrations. How do changes in $Q$ affect cell potential? From Equation 21.9, we see that ARCEI

- When $Q<1$ and thus [reactant] $>$ [product], $\ln Q<0$, so $E_{\text {cell }}>E_{\text {cell }}^{\circ}$.
- When $Q=1$ and thus [reactant] $=$ [product], $\ln Q=0$, so $E_{\text {cell }}=E_{\text {cell }}^{\circ}$.
- When $Q>1$ and thus [reactant] $<$ [product], $\ln Q>0$, so $E_{\text {cell }}<E_{\text {cell }}^{\circ}$.

As before, to obtain a simplified form of the Nernst equation for use in calculations, let's substitute known values of $R$ and $F$, operate the cell at 298.15 K , and convert to common (base-10) logarithms:

$$
\begin{aligned}
E_{\text {cell }}=E_{\text {cell }}^{\circ}-\frac{R T}{n F} \ln Q & =E_{\text {cell }}^{\circ}-2.303 \frac{R T}{n F} \log Q \\
& =E_{\text {cell }}^{\circ}-2.303 \times \frac{8.314 \frac{\mathrm{~J}}{\mathrm{~mol} \mathrm{rxn} \cdot \mathrm{~K}} \times 298.15 \mathrm{~K}}{\frac{n \mathrm{~mol} \mathrm{e}^{-}}{\mathrm{mol} \mathrm{rxn}}\left(9.65 \times 10^{4} \frac{\mathrm{~J}}{\mathrm{~V} \cdot \mathrm{~mol} \mathrm{e}^{-}}\right)} \log Q
\end{aligned}
$$

And we obtain:

$$
\begin{equation*}
E_{\mathrm{cell}}=E_{\mathrm{cell}}^{\circ}-\frac{0.0592 \mathrm{~V}}{n} \log Q \quad(\text { at } 298.15 \mathrm{~K}) \tag{21.10}
\end{equation*}
$$

Remember that the expression for $Q$ contains only those species with concentrations (and/or pressures) that can vary; thus, solids do not appear, even when they are the electrodes. For example, in the reaction between cadmium and silver ion, the Cd and Ag electrodes do not appear in the expression for $Q$ :

$$
\mathrm{Cd}(s)+2 \mathrm{Ag}^{+}(a q) \longrightarrow \mathrm{Cd}^{2+}(a q)+2 \mathrm{Ag}(s) \quad Q=\frac{\left[\mathrm{Cd}^{2+}\right]}{\left[\mathrm{Ag}^{+}\right]^{2}}
$$

## SAMPLE PROBLEM 21.6 Using the Nernst Equation to Calculate $E_{\text {cell }}$

PROBLEM In a test of a new reference electrode, a chemist constructs a voltaic cell consisting of a $\mathrm{Zn} / \mathrm{Zn}^{2+}$ half-cell and an $\mathrm{H}_{2} / \mathrm{H}^{+}$half-cell under the following conditions:

$$
\left[\mathrm{Zn}^{2+}\right]=0.010 \mathrm{M} \quad\left[\mathrm{H}^{+}\right]=2.5 \mathrm{M} \quad P_{\mathrm{H}_{2}}=0.30 \mathrm{~atm}
$$

Calculate $E_{\text {cell }}$ at 298.15 K .
PLAN To apply the Nernst equation and determine $E_{\text {cell }}$, we must know $E_{\text {cell }}^{\circ}$ and $Q$. We write the spontaneous reaction, calculate $E_{\text {cell }}^{\circ}$ from standard electrode potentials (Appendix D ), and use the given pressure and concentrations to find $Q$. (Recall that the ideal gas law allows us to use $P$ at constant $T$ as another way of writing concentration, $n / V$.) Then we substitute into Equation 21.10.
SOLUTION Determining the cell reaction and $E_{\text {cell }}^{\circ}$ :

$$
\begin{array}{rlrl}
2 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} & \longrightarrow \mathrm{H}_{2}(g) & E^{\circ} & =0.00 \mathrm{~V} \\
\mathrm{Zn}(s) & \longrightarrow \mathrm{Zn}^{2+}(a q)+2 \mathrm{e}^{-} & E^{\circ} & =-0.76 \mathrm{~V} \\
\hline 2 \mathrm{H}^{+}(a q)+\mathrm{Zn}(s) \longrightarrow \mathrm{H}_{2}(g)+\mathrm{Zn}^{2+}(a q) & E_{\text {cell }}^{\circ}=0.00 \mathrm{~V}-(-0.76 \mathrm{~V})=0.76 \mathrm{~V}
\end{array}
$$

Calculating $Q$ :

$$
Q=\frac{P_{\mathrm{H}_{2}} \times\left[\mathrm{Zn}^{2+}\right]}{\left[\mathrm{H}^{+}\right]^{2}}=\frac{0.30 \times 0.010}{2.5^{2}}=4.8 \times 10^{-4}
$$

Solving for $E_{\text {cell }}$ at $25^{\circ} \mathrm{C}(298.15 \mathrm{~K})$, with $n=2$ :

$$
\begin{aligned}
E_{\text {cell }} & =E_{\text {cell }}^{\circ}-2.303 \frac{R T}{n F} \log Q=E_{\text {cell }}^{\circ}-\frac{0.0592 \mathrm{~V}}{n} \log Q \\
& =0.76 \mathrm{~V}-\left[\frac{0.0592 \mathrm{~V}}{2} \log \left(4.8 \times 10^{-4}\right)\right]=0.76 \mathrm{~V}-(-0.0982 \mathrm{~V})=0.86 \mathrm{~V}
\end{aligned}
$$

CHECK After you check the arithmetic, reason through the answer: $E_{\text {cell }}>E_{\text {cell }}^{\circ}$ $(0.86>0.76)$ because the $\log Q$ term was negative, which is consistent with $Q<1$.
FOLLOW-UP PROBLEM 21.6 Consider a voltaic cell based on the following reaction: $\mathrm{Fe}(s)+\mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{Fe}^{2+}(a q)+\mathrm{Cu}(s)$. If $\left[\mathrm{Cu}^{2+}\right]=0.30 M$, what must $\left[\mathrm{Fe}^{2+}\right]$ be to increase $E_{\text {cell }}$ by 0.25 V above $E_{\text {cell }}^{\circ}$ at $25^{\circ} \mathrm{C}$ ?

## Changes in Potential During Cell Operation

Let's see how the potential of the zinc-copper cell changes as concentrations change during cell operation. In this case, the only concentrations that change are $[$ reactant $]=\left[\mathrm{Cu}^{2+}\right]$ and $[$ product $]=\left[\mathrm{Zn}^{2+}\right]$ :

$$
\mathrm{Zn}(s)+\mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{Cu}(s) \quad Q=\frac{\left[\mathrm{Zn}^{2+}\right]}{\left[\mathrm{Cu}^{2+}\right]}
$$

The positive $E_{\text {cell }}^{\circ}(1.10 \mathrm{~V})$ means that this reaction proceeds spontaneously from standard-state conditions, at which $\left[\mathrm{Zn}^{2+}\right]=\left[\mathrm{Cu}^{2+}\right]=1 M(Q=1)$, to some point at which $\left[\mathrm{Zn}^{2+}\right]>\left[\mathrm{Cu}^{2+}\right](Q>1)$. Now, suppose that we start the cell when $\left[\mathrm{Zn}^{2+}\right]<\left[\mathrm{Cu}^{2+}\right](Q<1)$, for example, when $\left[\mathrm{Zn}^{2+}\right]=1.0 \times 10^{-4} \mathrm{M}$ and $\left[\mathrm{Cu}^{2+}\right]=2.0 \mathrm{M}$. Thus, the cell potential is higher than the standard cell potential:

$$
\begin{aligned}
E_{\mathrm{cell}} & =E_{\mathrm{cell}}^{\circ}-\frac{0.0592 \mathrm{~V}}{2} \log \frac{\left[\mathrm{Zn}^{2+}\right]}{\left[\mathrm{Cu}^{2+}\right]}=1.10 \mathrm{~V}-\left(\frac{0.0592 \mathrm{~V}}{2} \log \frac{1.0 \times 10^{-4}}{2.0}\right) \\
& =1.10 \mathrm{~V}-\left[\frac{0.0592 \mathrm{~V}}{2}(-4.30)\right]=1.10 \mathrm{~V}+0.127 \mathrm{~V}=1.23 \mathrm{~V}
\end{aligned}
$$

As the cell operates, $\left[\mathrm{Zn}^{2+}\right]$ increases (as the Zn electrode deteriorates) and $\left[\mathrm{Cu}^{2+}\right]$ decreases (as Cu plates out on the Cu electrode). Although the changes during this process occur smoothly, if we keep Equation 21.10 in mind, we can

| Changes in $E_{\text {cell }}$ and Concentration |  |  |  |
| :--- | :---: | :---: | :---: |
| Stage in <br> cell <br> operation | $Q$ | Relative <br> $[P]$ and $[R]$ | $\frac{\mathbf{0 . 0 5 9 2} \mathrm{V}}{n} \log Q$ |
| 1. $E>E^{\circ}$ | $<1$ | $[\mathrm{P}]<[\mathrm{R}]$ | $<0$ |
| 2. $E=E^{\circ}$ | $=1$ | $[\mathrm{P}]=[\mathrm{R}]$ | $=0$ |
| 3. $E<E^{\circ}$ | $>1$ | $[\mathrm{P}]>[\mathrm{R}]$ | $>0$ |
| 4. $E=0$ | $=K$ | $[\mathrm{P}]>[\mathrm{R}]$ | $=E^{\circ}$ |

B

Figure 21.11 The relation between $E_{\text {cell }}$ and $\log Q$ for the zinc-copper cell.
A, A plot of $E_{\text {cell }}$ vs. $Q$ (on a logarithmic scale) for the zinc-copper cell shows a linear decrease. When $Q<1$ (left), [reactant] is relatively high, and the cell can do relatively more work. When $Q=1, E_{\text {cell }}=$ $E_{\text {cell. }}^{\circ}$ When $Q>1$ (right), [product] is relatively high, and the cell can do relatively less work. B, A summary of the changes in $E_{\text {cell }}$ as the cell operates, including the changes in $\left[\mathrm{Zn}^{2+}\right]$, denoted $[\mathrm{P}]$ for [product], and $\left[\mathrm{Cu}^{2+}\right]$, denoted $[\mathrm{R}]$ for [reactant].
identify four general stages of operation. Figure 21.11A shows the first three. The main point to note is that as the cell operates, its potential decreases:
Stage 1. $E_{\text {cell }}>E_{\text {cell }}^{\circ}$ when $Q<1$ : When the cell begins operation, $\left[\mathrm{Cu}^{2+}\right]>$ $\left[\mathrm{Zn}^{2+}\right]$, so the $[(0.0592 \mathrm{~V} / n) \log Q]$ term $<0$ and $E_{\text {cell }}>E_{\text {cell }}^{\circ}$.
As cell operation continues, $\left[\mathrm{Zn}^{2+}\right]$ increases and $\left[\mathrm{Cu}^{2+}\right]$ decreases; thus, $Q$ becomes larger, the $[(0.0592 \mathrm{~V} / n) \log Q]$ term becomes less negative (more positive), and $E_{\text {cell }}$ decreases.
Stage 2. $E_{\text {cell }}=E_{\text {cell }}^{\circ}$ when $Q=1$ : At the point when $\left[\mathrm{Cu}^{2+}\right]=\left[\mathrm{Zn}^{2+}\right], Q=1$, so the $[(0.0592 \mathrm{~V} / n) \log Q]$ term $=0$ and $E_{\text {cell }}=E_{\text {cell }}^{\circ}$.
Stage 3. $E_{\text {cell }}<E_{\text {cell }}^{\circ}$ when $Q>1$ : As the $\left[\mathrm{Zn}^{2+}\right] /\left[\mathrm{Cu}^{2+}\right]$ ratio continues to increase, the $[(0.0592 \mathrm{~V} / n) \log Q]$ term $>0$, so $E_{\text {cell }}<E_{\text {cell }}^{\circ}$.
Stage 4. $E_{\text {cell }}=0$ when $Q=K$ : Eventually, the $[(0.0592 \mathrm{~V} / n) \log Q]$ term
ADabecomeSsolarge thathinequalseentwhich means that $E_{\text {cell }}$ is zero. This occurs when the system reaches equilibrium: no more free energy is released, so the cell can do no more work. At this point, we say that a battery is "dead."
Figure 21.11B summarizes these four key stages in the operation of a voltaic cell. Let's find $K$ for the zinc-copper cell. At equilibrium, Equation 21.10 becomes

$$
0=E_{\mathrm{cell}}^{\circ}-\left(\frac{0.0592 \mathrm{~V}}{n}\right) \log K \text {, which rearranges to } E_{\mathrm{cell}}^{\circ}=\frac{0.0592 \mathrm{~V}}{n} \log K
$$

Note that this result is identical to Equation 21.8, which we obtained from $\Delta G^{\circ}$. Solving for $K$ of the zinc-copper cell ( $E_{\text {cell }}^{\circ}=1.10 \mathrm{~V}$ ),

$$
\log K=\frac{2 \times E_{\mathrm{cell}}^{\circ}}{0.0592 \mathrm{~V}}, \quad \text { so } \quad K=10^{(2 \times 1.10 \mathrm{~V}) / 0.0592 \mathrm{~V}}=10^{37.16}=1.4 \times 10^{37}
$$

Thus, the zinc-copper cell does work until the $\left[\mathrm{Zn}^{2+}\right] /\left[\mathrm{Cu}^{2+}\right]$ ratio is very high. To conclude, let's examine cell potential in terms of the starting $Q / K$ ratio:

- If $Q / K<1, E_{\text {cell }}$ is positive for the reaction as written. The smaller the $Q / K$ ratio, the greater the value of $E_{\text {cell }}$, and the more electrical work the cell can do.
- If $Q / K=1, E_{\text {cell }}=0$. The cell is at equilibrium and can no longer do work.
- If $Q / K>1, E_{\text {cell }}$ is negative for the reaction as written. The reverse reaction will take place, and the cell will do work until $Q / K$ equals 1 at equilibrium.

## Concentration Cells

If you mix a concentrated solution of a salt with a dilute solution of the salt, the final concentration equals some intermediate value. A concentration cell employs this phenomenon to generate electrical energy. The two solutions are in separate half-cells, so they do not mix; rather, their concentrations become equal as the cell operates.

How a Concentration Cell Works Suppose both compartments of a voltaic cell house the $\mathrm{Cu} / \mathrm{Cu}^{2+}$ half-reaction. The cell reaction is the sum of identical halfreactions, written in opposite directions, so the standard half-cell potentials cancel ( $\left.E_{\text {copper }}^{\circ}-E_{\text {copper }}^{\circ}\right)$ and $E_{\text {cell }}^{\circ}$ is zero. This occurs because standard electrode potentials are based on concentrations of 1 M . In a concentration cell, however, the half-reactions are the same but the concentrations are different. As a result, even though $E_{\text {cell }}^{\circ}$ equals zero, the nonstandard cell potential, $E_{\text {cell }}$, does not equal zero because it depends on the ratio of concentrations.

In Figure 21.12 A , a concentration cell has $0.10 \mathrm{Mu}^{2+}$ in the anode halfcell and $1.0 \mathrm{M} \mathrm{Cu}^{2+}$, a 10 -fold higher concentration, in the cathode half-cell:

$$
\begin{aligned}
& \mathrm{Cu}(s) \longrightarrow \mathrm{Cu}^{2+}(a q ; 0.10 M)+2 \mathrm{e}^{-} \begin{array}{l}
\text { [anode; oxidation] } \\
\mathrm{Cu}^{2+}(a q ; 1.0 M)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu}(s)
\end{array} \\
& \text { [cathode; reduction] }
\end{aligned}
$$

The overall cell reaction is the sum of the half-reactions:

$$
\mathrm{Cu}^{2+}(a q ; 1.0 \mathrm{M}) \longrightarrow \mathrm{Cu}^{2+}(a q ; 0.10 \mathrm{M}) \quad E_{\text {cell }}=\text { ? }
$$

The cell potential at the initial concentrations of 0.10 M (dilute) and 1.0 M (concentrated), with $n=2$, is obtained from the Nernst equation:

$$
\begin{aligned}
E_{\text {cell }} & =E_{\text {cell }}^{\circ}-\frac{0.0592 \mathrm{~V}}{2} \log \frac{\left[\mathrm{Cu}^{2+}\right]_{\text {dil }}}{\left[\mathrm{Cu}^{2+}\right]_{\text {conc }}}=0 \mathrm{~V}-\left(\frac{0.0592 \mathrm{~V}}{2} \log \frac{0.10 \mathrm{M}}{1.0 \mathrm{M}}\right) \\
& =0 \mathrm{~V}-\left[\frac{0.0592 \mathrm{~V}}{2}(-1.00)\right]=0.0296 \mathrm{~V}
\end{aligned}
$$

As you can see, because $E_{\text {cell }}^{\circ}$ for a concentration cell equals zero, $E_{\text {cell }}$ for nonstandard conditions depends entirely on the $[(0.0592 \mathrm{~V} / n) \log Q]$ term.

What is actually going on as this cell operates? In the half-cell with dilute electrolyte (anode), the Cu atoms in the electrode give up electrons and become $\mathrm{Cu}^{2+}$ ions, which enter the solution and make it more concentrated. The electrons
 concentrated solution pick up the electrons and become Cu atoms, which plate out on the electrode, so that solution becomes less concentrated. As in any voltaic cell, $E_{\text {cell }}$ decreases until equilibrium is attained, which happens when $\left[\mathrm{Cu}^{2+}\right]$ is the same in both half-cells (Figure 21.12B). The same final concentration would result if we mixed the two solutions, but no electrical work would be done.

$$
\begin{aligned}
& \text { Oxidation half-reaction } \\
& \mathrm{Cu}(s) \longrightarrow \mathrm{Cu}^{2+}(a q ; 0.10 \mathrm{M})+2 \mathrm{e}^{-}
\end{aligned}
$$

Figure 21.12 A concentration cell based on the $\mathrm{Cu} / \mathrm{Cu}^{2+}$ half-reaction. A, The half-reactions are the same, so $E_{\text {cell }}^{\circ}=0$. The cell operates because the half-cell concentrations are different, which makes $E_{\text {cell }}>0$ in this case. B, The cell operates until the half-cell concentrations are equal. Note the change in electrodes (exaggerated here for clarity) and the identical color of the solutions.

## SAMPLE PROBLEM 21.7 Calculating the Potential of a Concentration Cell

PROBLEM A concentration cell consists of two $\mathrm{Ag} / \mathrm{Ag}^{+}$half-cells. In half-cell A, electrode A dips into $0.010 \mathrm{M} \mathrm{AgNO}_{3}$; in half-cell B, electrode B dips into $4.0 \times 10^{-4} M \mathrm{AgNO}_{3}$. What is the cell potential at 298.15 K ? Which electrode has a positive charge?
PLAN The standard half-cell reactions are identical, so $E_{\text {cell }}^{\circ}$ is zero, and we calculate $E_{\text {cell }}$ from the Nernst equation. Because half-cell A has a higher $\left[\mathrm{Ag}^{+}\right], \mathrm{Ag}^{+}$ions will be reduced and plate out on electrode A . In half-cell $\mathrm{B}, \mathrm{Ag}$ will be oxidized and $\mathrm{Ag}^{+}$ions will enter the solution. As in all voltaic cells, reduction occurs at the cathode, which is positive.
SOLUTION Writing the spontaneous reaction: The $\left[\mathrm{Ag}^{+}\right]$decreases in half-cell A and increases in half-cell B , so the spontaneous reaction is

$$
\mathrm{Ag}^{+}(a q ; 0.010 M)[\text { half-cell } \mathrm{A}] \longrightarrow \mathrm{Ag}^{+}\left(a q ; 4.0 \times 10^{-4} M\right) \text { [half-cell B] }
$$

Calculating $E_{\text {cell }}$, with $n=1$ :

$$
\begin{aligned}
E_{\text {cell }} & =E_{\text {cell }}^{\circ}-\frac{0.0592 \mathrm{~V}}{1} \log \frac{\left[\mathrm{Ag}^{+}\right]_{\mathrm{dil}}}{\left[\mathrm{Ag}^{+}\right]_{\mathrm{conc}}}=0 \mathrm{~V}-\left(0.0592 \mathrm{~V} \log \frac{4.0 \times 10^{-4}}{0.010}\right) \\
& =0.0828 \mathrm{~V}
\end{aligned}
$$

Reduction occurs at the cathode, electrode $\mathrm{A}: \mathrm{Ag}^{+}(a q ; 0.010 M)+\mathrm{e}^{-} \longrightarrow \mathrm{Ag}(s)$. Thus, electrode A has a positive charge due to a relative electron deficiency.

FOLLOW-UP PROBLEM 21.7 A concentration cell is built using two $\mathrm{Au} / \mathrm{Au}^{3+}$ halfcells. In half-cell A, $\left[\mathrm{Au}^{3+}\right]=7.0 \times 10^{-4} M$, and in half-cell $\mathrm{B},\left[\mathrm{Au}^{3+}\right]=2.5 \times 10^{-2} \mathrm{M}$. What is $E_{\text {cell }}$, and which electrode is negative?

Concentration Cells in Your Nerve Cells The nerve cells that mediate every thought, movement, and other bodily process function by the principle of a concentration cell. The nerve membrane is imbedded with a host of specialized enzyme "gates" that use energy from ATP hydrolysis to separate an interior solution of low $\left[\mathrm{Na}^{+}\right]$and high $\left[\mathrm{K}^{+}\right]$from an exterior solution of high $\left[\mathrm{Na}^{+}\right]$and low $\left[\mathrm{K}^{+}\right]$. As a result of the differences in $\left[\mathrm{Na}^{+}\right]$and $\left[\mathrm{K}^{+}\right]$, the membrane is more positive outside than inside. One-third of the body's ATP is used to create and maintain these concentration differences. (The 1997 Nobel Prize in chemistry was shared by Jens C. Skou for elucidation of this enzyme mechanism.) When the nerve membrane is stimulated, $\mathrm{Na}^{+}$ions spontaneously rush in, and in 0.001 s , the inside of the membrane becomes more positive than the outside. This event is followed by $\mathrm{K}^{+}$ ions spontaneously rushing out; after another 0.001 s , the membrane is again more positive outside. These large changes in charge in one region of the membrane stimulate the neighboring region and the electrical impulse moves down the length of the cell.

Applications of Concentration Cells Chemists, biologists, and environmental scientists apply the principle of a concentration cell in a host of applications. Themesgimporimpisithe measarementotunknown ion concentrations, particularly $\left[\mathrm{H}^{+}\right]$. Suppose we construct a concentration cell based on the $\mathrm{H}_{2} / \mathrm{H}^{+}$halfreaction, in which the cathode compartment houses the standard hydrogen electrode and the anode compartment has the same apparatus dipping into an unknown $\left[\mathrm{H}^{+}\right]$in solution. The half-reactions and overall reaction are

$$
\begin{aligned}
\mathrm{H}_{2}(g ; 1 \mathrm{~atm}) & \longrightarrow 2 \mathrm{H}^{+}(a q ; \text { unknown })+2 \mathrm{e}^{-}
\end{aligned} \begin{aligned}
& \text { [anode; oxidation] } \\
& \text { [cathode; reduction] }
\end{aligned} \begin{aligned}
2 \mathrm{H}^{+}(a q ; 1 M)+2 \mathrm{e}^{-} & \mathrm{H}_{2}(g ; 1 \mathrm{~atm})
\end{aligned}
$$

As for the $\mathrm{Cu} / \mathrm{Cu}^{2+}$ concentration cell, $E_{\text {cell }}^{\circ}$ is zero; however, the half-cells differ in $\left[\mathrm{H}^{+}\right]$, so $E_{\text {cell }}$ is not zero. From the Nernst equation, with $n=2$, we obtain

$$
E_{\text {cell }}=E_{\text {cell }}^{\circ}-\frac{0.0592 \mathrm{~V}}{2} \log \frac{\left[\mathrm{H}^{+}\right]_{\text {unknown }}^{2}}{\left[\mathrm{H}^{+}\right]_{\text {standard }}^{2}}
$$

Substituting $1 M$ for $\left[\mathrm{H}^{+}\right]_{\text {standard }}$ and 0 V for $E_{\text {cell }}^{\circ}$ gives

$$
E_{\text {cell }}=0 \mathrm{~V}-\frac{0.0592 \mathrm{~V}}{2} \log \frac{\left[\mathrm{H}^{+}\right]_{\text {unknown }}^{2}}{1^{2}}=-\frac{0.0592 \mathrm{~V}}{2} \log \left[\mathrm{H}^{+}\right]_{\text {unknown }}^{2}
$$

Because $\log x^{2}=2 \log x$ (see Appendix A), we obtain

$$
E_{\text {cell }}=-\left[\frac{0.0592 \mathrm{~V}}{2}\left(2 \log \left[\mathrm{H}^{+}\right]_{\text {unknown }}\right)\right]=-0.0592 \mathrm{~V} \times \log \left[\mathrm{H}^{+}\right]_{\text {unknown }}
$$

Substituting $-\log \left[\mathrm{H}^{+}\right]=\mathrm{pH}$, we have

$$
E_{\text {cell }}=0.0592 \mathrm{~V} \times \mathrm{pH}
$$

Thus, by measuring $E_{\text {cell }}$, we can find the pH .
In the routine measurement of pH , a concentration cell incorporating two hydrogen electrodes is too bulky and difficult to maintain. Instead, as was pointed out in Chapter 18, a pH meter is used. As shown in Figure 21.13A, two separate electrodes dip into the solution being tested. One of them is a glass electrode,

which consists of an $\mathrm{Ag} / \mathrm{AgCl}$ half-reaction immersed in an HCl solution of fixed concentration (usually 1.000 M ) and enclosed by a thin ( $\sim 0.05 \mathrm{~mm}$ ) membrane made of a special glass that is highly sensitive to the presence of $\mathrm{H}^{+}$ions. The other electrode is a reference electrode, typically a saturated calomel electrode. It consists of a platinum wire immersed in a paste of $\mathrm{Hg}_{2} \mathrm{Cl}_{2}$ (calomel), liquid Hg , and saturated KCl solution. The glass electrode monitors the solution's $\left[\mathrm{H}^{+}\right]$ relative to its own fixed internal $\left[\mathrm{H}^{+}\right]$, and the instrument converts the potential difference between the glass and reference electrodes into a measure of pH . In modern instruments, a combination electrode is used, which houses both electrodes in one tube (Figure 21.13B).

The pH electrode is one example of an ion-selective (or ion-specific) electrode. Electrodes have been designed with highly specialized membranes in order to selectively measure the concentrations of many different ions in industrial, environmental, and biological samples Recent adeques allom heasurentin the picomolar-to-femtomolar $\left(10^{-12}-10^{-15} M\right)$ range. Table 21.3 shows a few of the many ions for which ion-selective electrodes are available.

Table 21.3 Some Ions Measured with Ion-Specific Electrodes

| Species Detected | Typical Sample |
| :--- | :--- |
| $\mathrm{NH}_{3} / \mathrm{NH}_{4}{ }^{+}$ | Industrial wastewater, seawater |
| $\mathrm{CO}_{2} / \mathrm{HCO}_{3}-$ | Blood, groundwater |
| $\mathrm{F}^{-} /$Drinking water, urine, soil, industrial stack gases $_{\mathrm{Br}^{-}}$ | Grain, plant tiscue |
| $\mathrm{I}^{-}$ | Milk, pharmaceuticals |
| $\mathrm{NO}_{3}-$ | Soil, fertilizer, drinking water |
| $\mathrm{K}^{+}$ | Blood serum, soil, wine |
| $\mathrm{H}^{+}$ | Laboratory solutions, soil, natural waters |

## Section Summary

A spontaneous process is indicated by a negative $\Delta G$ or a positive $E_{\text {cell }}$, which are related: $\Delta G=-n F E_{\text {cell }}$. The $\Delta G$ of the cell reaction represents the maximum amount of electrical work the cell can do. - Because the standard free energy change, $\Delta G^{\text {o }}$, is related to $E_{\text {cell }}^{\circ}$ and to $K$, we can use $E_{\text {cell }}^{\circ}$ to determine $K$. For nonstandard conditions, the Nernst equation shows that $E_{\text {cell }}$ depends on $E_{\text {cell }}^{\circ}$ and a correction term based on $Q . E_{\text {cell }}$ is high when $Q$ is small (high [reactant]), and it decreases as the cell operates. At equilibrium, $\Delta G$ and $E_{\text {cell }}$ are zero, which means that $Q=K$. $\bullet$ Concentration cells have identical half-reactions, but solutions of differing concentration; thus, they generate electrical energy as the concentrations become equal. • Ion-specific electrodes, such as the pH electrode, measure the concentration of one species.

Figure 21.13 The laboratory mea-
surement of pH . A, The glass electrode (left) is a self-contained $\mathrm{Ag} / \mathrm{AgCl}$ half-cell immersed in an HCl solution of known concentration and enclosed by a thin glass membrane. It monitors the external $\left[\mathrm{H}^{+}\right]$in the solution relative to its fixed internal $\left[\mathrm{H}^{+}\right]$. The saturated calomel electrode (right) acts as a reference. B, Most modern laboratories use a combination electrode, which houses both the glass and reference electrodes in one tube.

Minimicroanalysis Electronic miniaturization has greatly broadened the applications of electrochemistry. Environmental chemists use pocket-sized pH meters in the field to study natural waters and soil. Physiologists and biochemists employ electrodes so small that they can be surgically implanted in a single biological cell to study ion channels and receptors. In the photo, a microelectrode is recording the electrical impulses of a single neuron in a monkey's visual cortex.

### 21.5 ELECTROCHEMICAL PROCESSES IN BATTERIES

Because of their compactness and mobility, batteries have a major influence on our way of life. In industrialized countries, each person uses an average of 10 batteries per year! A battery, strictly speaking, is a self-contained group of voltaic cells arranged in series (plus-to-minus-to-plus, and so on), so that their individual voltages are added together. In everyday speech, however, the term may also be applied to a single voltaic cell. Batteries are ingeniously engineered devices that house rather unusual half-reactions and half-cells, but they operate through the same electrochemical principles we've been discussing. In this section, we examine the three categories of batteries-primary, secondary, and fuel cellsand note important examples, including some newer designs, of each.

## Primary (Nonrechargeable) Batteries

A primary battery cannot be recharged, so it is discarded when the components have reached their equilibrium concentrations, that is, when the cell is "dead." We'll discuss the alkaline battery, with a brief historical reference to the dry cell, the mercury and silver "button" batteries, and the primary lithium battery.
Alkaline Battery The precursor of today's ubiquitous alkaline battery, the common dry cell, or Leclanché cell, was invented in the 1860s and became a familiar household item during the first three-quarters of the $20^{\text {th }}$ century. The anode of the dry cell was a zinc can that housed a mixture of $\mathrm{MnO}_{2}$ and a weakly acidic electrolyte paste, consisting of $\mathrm{NH}_{4} \mathrm{Cl}, \mathrm{ZnCl}_{2}, \mathrm{H}_{2} \mathrm{O}$, and starch. Powdered graphite was used to improve conductivity, and the cathode was an inactive graphite rod. Even today, the cathode half-reaction is not completely understood, but it involved the reduction of $\mathrm{Mn}_{2}(s)$ 暂 $\mathrm{Mn}_{2} \mathrm{O}_{3}(s)$ and an acid-base reaction between $\mathrm{NH}_{4}{ }^{+}$ and-OH? At a high current drain, this reaction generated ammonia gas, which could build up and cause a serious voltage drop. Moreover, because the zinc anode reacted with the acidic $\mathrm{NH}_{4}{ }^{+}$ions, dry cells had a short shelf life.

Although more expensive than the dry cell, the alkaline battery avoids these drawbacks. The same electrode materials, zinc and manganese dioxide, are used, but the electrolyte is a paste of KOH and water. The half-reactions are essentially the same, but use of the KOH paste eliminates the $\mathrm{NH}_{3}$ gas buildup and maintains the Zn electrode (Figure 21.14):

$$
\begin{aligned}
& \text { Anode (oxidation): } \quad \mathrm{Zn}(s)+2 \mathrm{OH}^{-}(a q) \longrightarrow \mathrm{ZnO}(s)+\mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-} \\
& \text {Cathode (reduction): } \mathrm{MnO}_{2}(s)+2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Mn}(\mathrm{OH})_{2}(s)+2 \mathrm{OH}^{-}(a q) \\
& \text { Overall }(\text { cell }) \text { reaction: } \\
& \quad \mathrm{Zn}(s)+\mathrm{MnO}_{2}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{ZnO}(s)+\mathrm{Mn}(\mathrm{OH})_{2}(s) \quad E_{\text {cell }}=1.5 \mathrm{~V}
\end{aligned}
$$

Like the dry cell, the alkaline battery powers portable radios, toys, flashlights, and so on, is safe, and comes in many sizes. It has no voltage drop, longer shelf life, and better performance in terms of power capability and stored energy.

Figure 21.14 Alkaline battery.

Mercury and Silver (Button) Batteries Mercury and silver batteries are quite similar. Both use a zinc container as the anode (reducing agent) in a basic medium. The mercury battery employs HgO as the oxidizing agent, the silver uses $\mathrm{Ag}_{2} \mathrm{O}$, and both use a steel can around the cathode. The solid reactants are compacted with KOH and separated with moist paper. The half-reactions are
$\quad \mathrm{Zn}(s)+2 \mathrm{OH}^{-}($aq $) \longrightarrow \mathrm{ZnO}(s)+\mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-}$
$\begin{aligned} & \text { Anode (oxidation): } \\ & \text { Cathode (reduction) (mercury): } \mathrm{HgO}(s)+\mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Hg}(l)+2 \mathrm{OH}^{-}(a q) \\ & \text { Cathode (reduction) (silver): } \mathrm{Ag}_{2} \mathrm{O}(s)+\mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-} \longrightarrow 2 \mathrm{Ag}(s)+2 \mathrm{OH}^{-}(a q) \\ & \text { Overall (cell) reaction (mercury): } \\ & \quad \mathrm{Zn}(s)+\mathrm{HgO}(s) \longrightarrow \mathrm{ZnO}(s)+\mathrm{Hg}(l) \\ & \text { Overall (cell) reaction (silver): } \\ & \quad \mathrm{Zn}(s)+\mathrm{Ag}_{2} \mathrm{O}(s) \longrightarrow \mathrm{ZnO}(s)+2 \mathrm{Ag}(s) \quad E_{\text {cell }}=1.3 \mathrm{~V} \\ & \text { cell }=1.6 \mathrm{~V}\end{aligned}$
Both cells are manufactured as small button-sized batteries. The mercury cell is used in calculators (Figure 21.15). Because of its very steady output, the silver cell is used in watches, cameras, heart pacemakers, and hearing aids. Their major disadvantages are toxicity of discarded mercury and high cost of silver cells.

Primary Lithium Batteries The primary lithium battery is widely used in watches and implanted medical devices. It offers an extremely high energy/mass ratio, producing 1 mol of $\mathrm{e}^{-}(1 F)$ from less than 7 g of metal $(\mathcal{M}$ of $\mathrm{Li}=6.941 \mathrm{~g} / \mathrm{mol})$. The anode is lithium metal foil, which requires a nonaqueous electrolyte. The cathode is one of several metal oxides in which lithium ions lie between oxide layers. Some implantable medical devices have a silver vanadium oxide (SVO; $\mathrm{AgV}_{2} \mathrm{O}_{5.5}$ ) cathode and can provide power for several years, but at a low rate because energy storage is limited (Figure 21.16). The half-reactions are

| Anode (oxidation): | $3.5 \mathrm{Li}(s)$ | $\longrightarrow 3.5 \mathrm{Li}^{+}+3.5 \mathrm{e}^{-}$ |
| :---: | :---: | :---: |
| Cathode (reduction): | $\mathrm{gV}_{2} \mathrm{O}_{5.5}+3.5 \mathrm{Li}^{+}+3.5 \mathrm{e}^{-}$ | $\longrightarrow \mathrm{Li}_{3.5} \mathrm{AgV}_{2} \mathrm{O}_{5.5}$ |
| Overall (cell) reaction | $\mathrm{AgV}_{2} \mathrm{O}_{5.5}+3.5 \mathrm{Li}(s)$ | ) $\mathrm{Li}_{3.5} \mathrm{AgV}_{2} \mathrm{O}_{5.5}$ |

## Secondary (Rechargeable) Batteries

In contrast to primary batteries, a secondary, or rechargeable, battery is recharged when it runs down by supplying electrical energy to reverse the cell reaction and re-form reactant. In other words, in this type of battery, the voltaic cells are periodically converted to electrolytic cells to restore nonequilibrium concentrations of the cell components. By far the most widely used secondary battery is the common car battery. Two newer types are the nickel-metal hydride battery and the lithium-ion battery, a secondary version of a lithium battery.

Lead-Acid Battery A typical lead-acid car battery has six cells connected in series, each of which delivers about 2.1 V for a total of about 12 V . Each cell contains two lead grids loaded with the electrode materials: high-surface-area (spongy) Pb in the anode and high-surface-area $\mathrm{PbO}_{2}$ in the cathode. The grids are immersed in an electrolyte solution of $\sim 4.5 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$. Fiberglass sheets between the grids prevent

Figure 21.15 Silver button battery.

Figure 21.16 Lithium battery.

Figure 21.17 Lead-acid battery.
shorting due to physical contact (Figure 21.17). When the cell discharges, it generates electrical energy as a voltaic cell:
Anode (oxidation): $\quad \mathrm{Pb}(s)+\mathrm{HSO}_{4}^{-}(a q) \longrightarrow \mathrm{PbSO}_{4}(s)+\mathrm{H}^{+}+2 \mathrm{e}^{-}$
Cathode (reduction):

$$
\mathrm{PbO}_{2}(s)+3 \mathrm{H}^{+}(a q)+\mathrm{HSO}_{4}^{-}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{PbSO}_{4}(s)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

Notice that both half-reactions produce $\mathrm{Pb}^{2+}$ ions, one through the oxidation of Pb , the other through the reduction of $\mathrm{PbO}_{2}$. The $\mathrm{Pb}^{2+}$ forms $\mathrm{PbSO}_{4}(s)$ at both electrodes by reacting with $\mathrm{HSO}_{4}{ }^{-}$.
Overall (cell) reaction (discharge):

$$
\mathrm{PbO}_{2}(s)+\mathrm{Pb}(s)+2 \mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow 2 \mathrm{PbSO}_{4}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \quad E_{\text {cell }}=2.1 \mathrm{~V}
$$

When the cell is recharged, it uses electrical energy as an electrolytic cell, and the half-cell and overall reactions are reversed.
Overall (cell) reaction (recharge):

$$
2 \mathrm{PbSO}_{4}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{PbO}_{2}(s)+\mathrm{Pb}(s)+2 \mathrm{H}_{2} \mathrm{SO}_{4}(a q)
$$

For more than a century, car and truck owners have relied on the lead-acid battery to provide the large burst of current to the starter motor needed to start the engine-and to do so for years in both hot and cold weather. Nevertheless, there are problems with the lead-acid battery, mainly loss of capacity and safety concerns. Loss of capacity arises from several factors, including corrosion of the positive $(\mathrm{Pb})$ grid, detachment of active material as a result of normal mechanical bumping, and the formation of large crystals of $\mathrm{PbSO}_{4}$, which make recharging more difficult. Most of the safety concerns have been remedied in modern batteries. Older batteries had a cap on each cell for monitoring electrolyte density and replacing water lost on overcharging. During recharging, some water could be electrolyzed to $\mathrm{H}_{2}$ and $\mathrm{O}_{2}$, which could explode if sparked, and splatter
 normal operation, and they use flame attenuators to reduce the explosion hazard.
Nickel-Metal Hydride (Ni-MH) Battery Concerns about the toxicity of the nickelcadmium (nicad) battery are leading to its replacement by the nickel-metal hydride battery. The anode half-reaction oxidizes the hydrogen absorbed within a metal alloy (designated M ; e.g., $\mathrm{LaNi}_{5}$ ) in a basic ( KOH ) electrolyte, while nickel(III) in the form of $\mathrm{NiO}(\mathrm{OH})$ is reduced at the cathode (Figure 21.18):
Anode (oxidation): $\quad \mathrm{MH}(s)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{M}(s)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{e}^{-}$
Cathode (reduction): $\mathrm{NiO}(\mathrm{OH})(s)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{e}^{-} \longrightarrow \mathrm{Ni}(\mathrm{OH})_{2}(s)+\mathrm{OH}^{-}(a q)$
Overall (cell) reaction: $\quad \mathrm{MH}(s)+\mathrm{NiO}(\mathrm{OH})(s) \longrightarrow \mathrm{M}(s)+\mathrm{Ni}(\mathrm{OH})_{2}(s)$

$$
E_{\text {cell }}=1.4 \mathrm{~V}
$$

The cell reaction is reversed during recharging. The Ni-MH battery is common in cordless razors, camera flash units, and power tools. It is lightweight, has high power, and is nontoxic, but it may discharge excessively during long-term storage.

Lithium-Ion Battery The secondary lithium-ion battery has an anode of Li atoms that lie between sheets of graphite (designated $\mathrm{Li}_{x} \mathrm{C}_{6}$ ). The cathode is a lithium metal oxide, such as $\mathrm{LiMn}_{2} \mathrm{O}_{4}$ or $\mathrm{LiCoO}_{2}$, and a typical electrolyte is $1 M \mathrm{LiPF}_{6}$ in an organic solvent, such as dimethyl carbonate (often mixed with methylethyl carbonate). Electrons flow through the circuit, while solvated $\mathrm{Li}^{+}$ ions flow from anode to cathode within the cell, as shown in Figure 21.19. The cell reactions are
$\quad \mathrm{Li}_{x} \mathrm{C}_{6} \longrightarrow x \mathrm{Li}^{+}+x \mathrm{e}^{-}+\mathrm{C}_{6}(s)$
$\begin{aligned} & \text { Anode (oxidation): } \\ & \text { Cathode (reduction): } \mathrm{Li}_{1-x} \mathrm{Mn}_{2} \mathrm{O}_{4}(s)+x \mathrm{Li}^{+}+x \mathrm{e}^{-} \longrightarrow \mathrm{LiMn}_{2} \mathrm{O}_{4}(s) \\ & \text { Overall (cell) reaction: } \quad \mathrm{Li}_{x} \mathrm{C}_{6}+\mathrm{Li}_{1-x} \mathrm{Mn}_{2} \mathrm{O}_{4}(s) \longrightarrow \mathrm{LiMn}_{2} \mathrm{O}_{4}(s)+\mathrm{C}_{6}(s) \\ & \quad E_{\text {cell }}=3.7 \mathrm{~V}\end{aligned}$
The cell reaction is reversed during recharging. The lithium-ion battery powers countless laptop computers, cell phones, and camcorders. Its key drawbacks are expense and the flammability of the organic solvent.

## Fuel Cells

In contrast to primary and secondary batteries, a fuel cell, sometimes called a flow battery, is not self-contained. The reactants (usually a combustible fuel and oxygen) enter the cell, and the products leave the cell, generating electricity through the controlled oxidation of the fuel. In other words, fuel cells use combustion to produce electricity. The fuel does not burn because, as in other batteries, the half-reactions are separated, and the electrons are transferred through an external circuit.

The most common fuel cell being developed for use in cars is the proton exchange membrane (PEM) cell, which uses $\mathrm{H}_{2}$ as the fuel and has an operating temperature of around $80^{\circ} \mathrm{C}$ (Figure 21.20 ghe celldeactions arhancer Anode (oxidation): $\quad 2 \mathrm{H}_{2}(g) \longrightarrow 4 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-}$
Cathode (reduction): $\mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(g)$
Overall (cell) reaction: $\quad 2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{g}) \quad E_{\text {cell }}=1.2 \mathrm{~V}$
The reactions in fuel cells have much lower rates than those in other batteries, so they require an electrocatalyst to decrease the activation energy (Section 16.8). The PEM cell electrodes are composites consisting of nanoparticles of a Pt-based catalyst deposited on graphite. These are embedded in a polymer electrolyte membrane having a perfluoroethylene backbone ( $-\mathrm{FF}_{2} \mathrm{C}-\mathrm{CF}_{2} \jmath_{n}$ ) with attached sulfonic acid groups $\left(\mathrm{RSO}_{3}{ }^{-}\right)$that play a key role in ferrying protons from anode to cathode. At the anode, two $\mathrm{H}_{2}$ molecules adsorb onto the catalyst and are split and oxidized. From each $\mathrm{H}_{2}$, two $\mathrm{e}^{-}$travel through the wire to the cathode, while two $\mathrm{H}^{+}$become hydrated and migrate through the electrolyte as $\mathrm{H}_{3} \mathrm{O}^{+}$. According to a proposed multistep mechanism, at the cathode, an $\mathrm{O}_{2}$ molecule adsorbs onto the catalyst, which provides an $\mathrm{e}^{-}$to form $\mathrm{O}_{2}{ }^{-}$. One $\mathrm{H}_{3} \mathrm{O}^{+}$donates its $\mathrm{H}^{+}$to the $\mathrm{O}_{2}^{-}$, forming $\mathrm{HO}_{2}$ (that is, $\mathrm{HO}-\mathrm{O}$ ). The $\mathrm{O}-\mathrm{O}$ bond stretches and breaks as another $\mathrm{H}_{3} \mathrm{O}^{+}$ gives its $\mathrm{H}^{+}$and the catalyst provides another $\mathrm{e}^{-}$: the first $\mathrm{H}_{2} \mathrm{O}$ has formed. In similar fashion, a third $\mathrm{H}^{+}$and $\mathrm{e}^{-}$attach to the freed O atom to form OH , and a fourth $\mathrm{H}^{+}$and $\mathrm{e}^{-}$are transferred to form the second $\mathrm{H}_{2} \mathrm{O}$. Both water molecules desorb and leave the cell.

Hydrogen fuel cells have been used for years to provide electricity and pure water during space flights. In the very near future, similar ones will supply electric power for transportation, residential, and commercial needs. Already, every major car manufacturer has a fuel-cell prototype. By themselves, these cells produce no pollutants, and they convert about $75 \%$ of the fuel's bond energy into

Figure 21.19 Lithium-ion battery.
useable power, in contrast to $40 \%$ for a coal-fired power plant and $25 \%$ for a gasoline-powered car engine. Of course, their overall environmental impact will depend on how the $\mathrm{H}_{2}$ is obtained; for example, electrolyzing water with solar power will have a negligible impact, whereas electrolyzing it with electricity from a coal-fired plant will have a sizeable one. Despite steady progress, current fuelcell research remains focused on lowering costs by improving membrane conductivity and developing more efficient electrocatalysts.

## Section Summary

Batteries contain several voltaic cells in series and are classified as primary (e.g., alkaline, mercury, silver, and lithium), secondary (e.g., lead-acid, nickel-metal hydride, and lithium-ion), or fuel cell. - Supplying electricity to a rechargeable (secondary) battery reverses the redox reaction, forming more reactant for further use. - Fuel cells generate a current through the controlled oxidation of a fuel such as $\mathrm{H}_{2}$.

### 21.6 CORROSION: A CASE OF ENVIRONMENTAL ELECTROCHEMISTRY

By now, you may be thinking that spontaneous electrochemical processes are always beneficial, but consider the problem of corrosion, the natural redox process that oxidizes metals to their oxides and sulfides. In chemical terms, corrosion is the reverse of isolating a metal from its oxide or sulfide ore; in electrochemical terms, the process shares many similarities with the operation of a voltaic cell. Damage from corrosion to cars, ships, buildings, and bridges runs into tens of billions of dollars annually, so it is a major problem in much of the world. Although yye foçus here on the corrosion of iron, many other metals, such as copperand sitver, also conode.

## The Corrosion of Iron

The most common and economically destructive form of corrosion is the rusting of iron. About $25 \%$ of the steel produced in the United States is made just to replace steel already in use that has corroded. Contrary to the simplified equation presented earlier, rust is not a direct product of the reaction between iron and oxygen but arises through a complex electrochemical process. Let's look at the facts of iron corrosion and then use the features of a voltaic cell to explain them:

1. Iron does not rust in dry air: moisture must be present.
2. Iron does not rust in air-free water: oxygen must be present.
3. The loss of iron and the depositing of rust often occur at different places on the same object.
4. Iron rusts more quickly at low pH (high $\left[\mathrm{H}^{+}\right]$).
5. Iron rusts more quickly in contact with ionic solutions.
6. Iron rusts more quickly in contact with a less active metal (such as Cu ) and more slowly in contact with a more active metal (such as Zn ).

Picture the magnified surface of a piece of iron or steel (Figure 21.21). Strains, ridges, and dents in contact with water are typically the sites of iron loss (fact 1). These sites are called anodic regions because the following half-reaction occurs there:

$$
\mathrm{Fe}(s) \longrightarrow \mathrm{Fe}^{2+}(a q)+2 \mathrm{e}^{-} \quad \text { [anodic region; oxidation] }
$$

Once the iron atoms lose electrons, the damage to the object has been done, and a pit forms where the iron is lost.

The freed electrons move through the external circuit-the piece of iron itself-until they reach a region of relatively high $\mathrm{O}_{2}$ concentration (fact 2), near

Figure 21.21 The corrosion of iron. A, A close-up view of an iron surface. Corrosion usually occurs at a surface irregularity. B, A sche-
matic depiction of a small area of the surface, showing the steps in the corrosion process.
the surface of a surrounding water droplet, for instance. At this cathodic region, the electrons released from the iron atoms reduce $\mathrm{O}_{2}$ molecules:

$$
\mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l) \quad \text { [cathodic region; reduction] }
$$

Notice that this overall redox process is complete; thus, the iron loss has occurred without any rust forming:

$$
2 \mathrm{Fe}(s)+\mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q) \longrightarrow 2 \mathrm{Fe}^{2+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

Rust forms through another redox reaction in which the reactants make direct contact. The $\mathrm{Fe}^{2+}$ ions formed originally at the anodic region disperse through the surrounding water and react with oroftem at some distapeefirm the pitefact 3). The overall reaction for this step is

$$
2 \mathrm{Fe}^{2+}(a q)+\frac{1}{2} \mathrm{O}_{2}(g)+(2+n) \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Fe}_{2} \mathrm{O}_{3} \cdot n \mathrm{H}_{2} \mathrm{O}(s)+4 \mathrm{H}^{+}(a q)
$$

[The inexact coefficient $n$ for $\mathrm{H}_{2} \mathrm{O}$ in the above equation appears because rust, $\mathrm{Fe}_{2} \mathrm{O}_{3} \cdot n \mathrm{H}_{2} \mathrm{O}$, is a form of iron(III) oxide with a variable number of waters of hydration.] The rust deposit is really incidental to the damage caused by loss of iron-a chemical insult added to the original injury.

Adding the previous two equations together shows the overall equation for the rusting of iron:

$$
2 \mathrm{Fe}(s)+\frac{3}{2} \mathrm{O}_{2}(g)+n \mathrm{H}_{2} \mathrm{O}(l)+4 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Fe}_{2} \mathrm{O}_{3} \cdot n \mathrm{H}_{2} \mathrm{O}(s)+4 \mathrm{H}^{+}(a q)
$$

The canceled $\mathrm{H}^{+}$ions are shown to emphasize that they act as a catalyst; that is, they speed the process as they are used up in one step of the overall reaction and created in another. As a result of this action, rusting is faster at low pH (high $\left[\mathrm{H}^{+}\right]$) (fact 4). Ionic solutions speed rusting by improving the conductivity of the aqueous medium near the anodic and cathodic regions (fact 5). The effect of ions is especially evident on ocean-going vessels (Figure 21.22) and on the underbodies and around the wheel wells of cars driven in cold climates, where salts are used to melt ice on slippery roads.

In many ways, the components of the corrosion process resemble those of a voltaic cell:

- Anodic and cathodic regions are separated in space.
- The regions are connected via an external circuit through which the electrons travel.
- In the anodic region, iron behaves like an active electrode, whereas in the cathodic region, it is inactive.
- The moisture surrounding the pit functions somewhat like a salt bridge, a means for ions to ferry back and forth and keep the solution neutral.

Figure 21.22 Enhanced corrosion at sea. The high ion concentration of seawater leads to its high conductivity, which enhances the corrosion of iron in the hulls and anchors of ocean-going vessels.

Figure 21.23 The effect of metal-metal contact on the corrosion of iron. A, When iron is in contact with a less active metal, such as copper, the iron loses electrons more readily (is more anodic), so it corrodes faster. B, When iron is in contact with a more active metal, such as zinc, the zinc acts as the anode and loses electrons. Therefore, the iron is cathodic, so it does not corrode. The process is known as cathodic protection.

Figure 21.24 The use of sacrificial anodes to prevent iron corrosion.
In cathodic protection, an active metal, such as magnesium or aluminum, is connected to underground iron pipes to prevent their corrosion. The active metal is sacrificed instead of the iron.

## Protecting Against the Corrosion of Iron

A common approach to preventing or limiting corrosion is to eliminate contact with the corrosive factors. The simple act of washing off road salt removes the ionic solution from auto bodies. Iron objects are frequently painted to keep out $\mathrm{O}_{2}$ and moisture, but if the paint layer chips, rusting proceeds. More permanent coatings include chromium plated on plumbing fixtures. In the "blueing" of gun barrels, wood stoves, and other steel objects, an adherent coating of $\mathrm{Fe}_{3} \mathrm{O}_{4}$ (magnetite) is bonded to the surface.

The only fact regarding corrosion that we have not yet addressed concerns the relative activity of other metals in contact with iron (fact 6), which leads to the most effective way to prevent corrosion. The essential idea is that iron functions as both anode and cathode in the rusting process, but it is lost only at the anode. Therefore, anything that makes iron behave more like the anode increases
 active metal (weaker reducing agent), such as copper, its anodic function is enhanced. As a result, when iron plumbing is connected directly to copper plumbing, the iron pipe corrodes rapidly.

On the other hand, anything that makes iron behave more like the cathode prevents corrosion. In cathodic protection. iron makes contact with a more active metal (stronger reducing agent), such as zinc. The iron becomes cathodic and remains intact, while the zinc acts as the anode and loses electrons (Figure 21.23B). Coating steel with a "sacrificial" layer of zinc is the basis of the galvanizing process. In addition to blocking physical contact with $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{O}_{2}$, the zinc is "sacrificed" (oxidized) instead of the iron.

Sacrificial anodes are employed to protect iron and steel structures (pipes, tanks, oil rigs, and so on) in marine and moist underground environments. The metals that are most frequently used for this purpose are magnesium and aluminum because they are much more active than iron. As a result, they act as the anode while iron acts as the cathode (Figure 21.24). Another advantage of these metals is that they form adherent oxide coatings, which slows their own corrosion.

## Section Summary

Corrosion damages metal structures through a natural electrochemical change. - Iron corrosion occurs in the presence of oxygen and moisture and is increased by high [ $\mathrm{H}^{+}$], high [ion], or contact with a less active metal, such as Cu . Fe is oxidized and $\mathrm{O}_{2}$ is reduced in one redox reaction, while rust (hydrated form of $\mathrm{Fe}_{2} \mathrm{O}_{3}$ ) is formed in another reaction that often takes place at a different location. Because Fe functions as both anode and cathode in the process, an iron or steel object can be protected by physically covering its surface or joining it to a more active metal (such as $\mathrm{Zn}, \mathrm{Mg}$, or All, which acts as the anode in place of the Fe.

### 21.7 ELECTROLYTIC CELLS: USING ELECTRICAL ENERGY TO DRIVE NONSPONTANEOUS REACTIONS

Up to now, we've been considering voltaic cells, those that generate electrical energy from a spontaneous redox reaction. The principle of an electrolytic cell is exactly the opposite: electrical energy from an external source drives a nonspontaneous reaction.

## Construction and Operation of an Electrolytic Cell

Let's examine the operation of an electrolytic cell by constructing one from a voltaic cell. Consider the tin-copper voltaic cell in Figure 21.25A. The Sn anode will gradually become oxidized to $\mathrm{Sn}^{2+}$ ions, and the $\mathrm{Cu}^{2+}$ ions will gradually be reduced and plate out on the Cu cathode because the cell reaction is spontaneous in that direction:

For the voltaic cell

|  | $\mathrm{Sn}(s) \longrightarrow \mathrm{Sn}^{2+}(a q)+2 \mathrm{e}^{-}$ |  |
| :--- | :--- | :--- |
| $\mathrm{Cu}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu}(s)$ | [anode; oxidation] <br> [cathode; reduction] |  |
| $\mathrm{Sn}(s)+\mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{Sn}^{2+}(a q)+\mathrm{Cu}(s)$ |  | $E_{\text {cell }}^{\circ}=0.48 \mathrm{~V}$ and $\Delta G^{\circ}=-93 \mathrm{~kJ}$ |

Therefore, the reverse cell reaction is nonspontaneous and never happens of its own accord, as the negative $E_{\text {cell }}^{\circ}$ and positive $\Delta G^{\circ}$ indicate:

$$
\mathrm{Cu}(s)+\mathrm{Sn}^{2+}(a q) \longrightarrow \mathrm{Cu}^{2+}(a q)+\mathrm{Sn}(s) \quad E_{\text {cell }}^{\circ}=-0.48 \mathrm{~V} \text { and } \Delta G^{\circ}=93 \mathrm{~kJ}
$$

However, we can make this process happen by supplying from an external source an electric potential greater than $E_{\text {cell }}^{\circ}$. In effect, we have converted the voltaic cell into an electrolytic cell and changed the nature of the electrodes-anode is now cathode, and cathode is now anode (Figure 21.25B):

For the electrolytic cell

Oxidation half-reaction
$\mathrm{Sn}(s) \longrightarrow \mathrm{Sn}^{2+}(a q)+2 \mathrm{e}^{-}$

$$
\begin{gathered}
\text { Overall (cell) reaction } \\
\mathrm{Sn}(\mathrm{~s})+\mathrm{Cu}^{2+}(a q) \xrightarrow{\longrightarrow} \mathrm{Sn}^{2+}(a q)+\mathrm{Cu}(s)
\end{gathered}
$$

A Voltaic cell
B Electrolytic cell

Figure 21.25 The tin-copper reaction as the basis of a voltaic and an electrolytic cell. A, At standard conditions, the spontaneous reaction between Sn and $\mathrm{Cu}^{2+}$ generates 0.48 V in a voltaic cell. B, If more than 0.48 V is supplied, the same apparatus and components become an electrolytic cell, and the nonspontaneous reaction between Cu and $\mathrm{Sn}^{2+}$ occurs. Note the changes in electrode charges and direction of electron flow.

Note that in an electrolytic cell, as in a voltaic cell, oxidation takes place at the anode and reduction takes place at the cathode, but the direction of electron flow and the signs of the electrodes are reversed.

To understand these changes, keep in mind the cause of the electron flow:

- In a voltaic cell, electrons are generated at the anode, so it is negative, and electrons are consumed at the cathode, so it is positive.
- In an electrolytic cell, the electrons come from the external power source, which supplies them to the cathode, so it is negative, and removes them from the anode, so it is positive.

A rechargeable battery functions as a voltaic cell when it is discharging and as an electrolytic cell when it is recharging, so it provides a good way to compare these two cell types and the changes in the processes and charges of the electrodes. Figure 21.26 shows these changes in the lead-acid battery. In the discharge mode (voltaic cell), oxidation occurs at electrode I, thus making the negative electrode the anode. In the recharge mode (electrolytic cell), oxidation occurs at electrode II, thus making the positive electrode the anode. Similarly, the cathode is positive during discharge (electrode II) and negative during recharge (electrode I). To reiterate, regardless of whether the cell is discharging or recharging, oxidation occurs at the anode and reduction occurs at the cathode.

Table 21.4 Comparison of Voltaic and Electrolytic Cells

|  |  |  | Electrode |  |  |
| :--- | :---: | :---: | :--- | :--- | :---: |
| Cell Type | $\boldsymbol{\Delta G}$ | $\boldsymbol{E}_{\text {cell }}$ | Name | Process | Sign |
| Voltaic | $<0$ | $>0$ | Anode | Oxidation | - |
| Voltaic | $<0$ | $>0$ | Cathode | Reduction | + |
| Electrolytic | $>0$ | $<0$ | Anode | Oxidation | + |
| Electrolytic | $>0$ | $<0$ | Cathode | Reduction | - |

Table 21.4 summarizes the processes and signs in the two types of electrochemical cells.

## Predicting the Products of Electrolysis

Electrolysis, the splitting (lysing) of a substance by the input of electrical energy, is often used to decompose a compound into its elements. Electrolytic cells are involved in key industrial production steps for some of the most commercially important elements, including chlorine, aluminum, and copper, as you'll see in Chapter 22. The first laboratory electrolysis of $\mathrm{H}_{2} \mathrm{O}$ to $\mathrm{H}_{2}$ and $\mathrm{O}_{2}$ was performed in 1800 , and the process is still used to produce these gases in ultrahigh purity. The electrolyte in an electrolytic cell can be the pure compound (such as $\mathrm{H}_{2} \mathrm{O}$ or a molten salt), a mixture of molten salts, or an aqueous solution of a salt. The products obtained depend on atomic properties and several other factors, so let's examine some actual cases.
Electrolysis of Pure Molten Salts Mreyetectioly in ap lications Invelye isodating a metal or nonmetal from a molten salt. Predicting the product at each electrode is simple if the salt is pure because the cation will be reduced and the anion oxidized. The electrolyte is the molten salt itself, and the ions move through the cell because they are attracted by the oppositely charged electrodes.

Consider the electrolysis of molten (fused) calcium chloride. The two species present are $\mathrm{Ca}^{2+}$ and $\mathrm{Cl}^{-}$, so $\mathrm{Ca}^{2+}$ ion is reduced and $\mathrm{Cl}^{-}$ion is oxidized:

$$
\begin{aligned}
2 \mathrm{Cl}^{-}(l) \longrightarrow \mathrm{Cl}_{2}(g)+2 \mathrm{e}^{-} & \begin{array}{l}
\text { [anode; oxidation] } \\
\text { [cathode; reduction] }
\end{array} \\
\hline \mathrm{Ca}^{2+}(l)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Ca}(s) & {\left[\mathrm{Ca}^{-}(l) \longrightarrow \mathrm{Ca}(s)+\mathrm{Cl}_{2}(g)\right.}
\end{aligned}
$$

Metallic calcium is prepared industrially this way, as are several other active metals, such as Na and Mg , and the halogens $\mathrm{Cl}_{2}$ and $\mathrm{Br}_{2}$. We examine the details of these and several other electrolytic processes in Chapter 22.
Electrolysis of Mixed Molten Salts More typically, the electrolyte is a mixture of molten salts, which is then electrolyzed to obtain a particular metal. When we have a choice of product, how can we tell which species will react at which electrode? The general rule for all electrolytic cells is that the more easily oxidized species (stronger reducing agent) reacts at the anode, and the more easily reduced species (stronger oxidizing agent) reacts at the cathode.

It's important to realize that for electrolysis of mixtures of molten salts, we cannot use tabulated $E^{\circ}$ values to tell the relative strength of the oxidizing and reducing agents. Those values refer to the change from aqueous ion to free element, $\mathrm{M}^{n+}(a q)+n \mathrm{e}^{-} \longrightarrow \mathrm{M}(s)$, under standard-state conditions, but there are no aqueous ions in a molten salt. Instead, we rely on our knowledge of periodic atomic trends to predict which of the ions present gains or loses electrons more easily (Sections 8.4 and 9.5).

Reduction half-reaction $2 \mathrm{H}_{2} \mathrm{O}(I)+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(g)+2 \mathrm{OH}^{-}(a q)$

Overall (cell) reaction
$2 \mathrm{H}_{2} \mathrm{O}(I) \longrightarrow 2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g)$
Figure 21.27 The electrolysis of water.
A certain volume of oxygen forms through the oxidation of $\mathrm{H}_{2} \mathrm{O}$ at the anode (right), and twice that volume of hydrogen forms through the reduction of $\mathrm{H}_{2} \mathrm{O}$ at the cathode (left).

## SAMPLE PROBLEM 21.8 Predicting the Electrolysis Products of a Molten Salt Mixture

PROBLEM A chemical engineer melts a naturally occurring mixture of NaBr and $\mathrm{MgCl}_{2}$ and decomposes it in an electrolytic cell. Predict the substance formed at each electrode, and write balanced half-reactions and the overall cell reaction.
PLAN We have to determine which metal and nonmetal will form more easily at the electrodes. We first list the ions as oxidizing or reducing agents. If one metal holds its electrons more tightly than another, it has a higher ionization energy (IE). Therefore, as a cation, it gains electrons more easily; it is the stronger oxidizing agent and is reduced at the cathode. Similarly, if one nonmetal holds its electrons less tightly than another, it has a lower electronegativity (EN). Therefore, as an anion, it loses electrons more easily; it is the stronger reducing agent and is oxidized at the anode.
SOLUTION Listing the ions as oxidizing or reducing agents:

> The possible oxidizing agents are $\mathrm{Na}^{+}$and $\mathrm{Mg}^{2+}$.
> The possible reducing agents are $\mathrm{Br}^{-}$and $\mathrm{Cl}^{-}$.

Determining the cathode product (more easily reduced cation): Mg is to the right of Na in Period 3. IE increases from left to right, so Mg has a higher IE. It takes more energy to remove an $\mathrm{e}^{-}$from Mg than from Na , so it follows that $\mathrm{Mg}^{2+}$ has a greater attraction for $\mathrm{e}^{-}$and thus is more easily reduced (stronger oxidizing agent):

$$
\mathrm{Mg}^{2+}(l)+2 \mathrm{e}^{-} \longrightarrow \operatorname{Mg}(l) \quad[\text { cathode; reduction] }
$$

Determining the anode product (more easily oxidized anion): Br is below Cl in Group 7A(17). EN decreases down the group, so Br has a lower EN than Cl. Therefore, it follows that $\mathrm{Br}^{-}$holds its $\mathrm{e}^{-}$less tightly than $\mathrm{Cl}^{-}$, so $\mathrm{Br}^{-}$is more easily oxidized (stronger reducing agent):

$$
2 \mathrm{Br}^{-}(l) \longrightarrow \mathrm{Br}_{2}(g)+2 \mathrm{e}^{-} \quad[\text { anode; oxidation] }
$$

Writing the overall cell reaction:

$$
\operatorname{Mg}^{2+}(l)+2 \mathrm{Br}^{-}(l) \longrightarrow \mathrm{Mg}(l)+\mathrm{Br}_{2}(g) \quad[\text { overall }]
$$

COMMENT The cell temperature must be high enough to keep the salt mixture molten. In this case, the temperature is greater than the melting point of Mg , so it appears as a liquid in the equation, and greater than the boiling point of $\mathrm{Br}_{2}$, so it appears as a gas.
FOLLOW-UP PROBLEM 21.8 A sample of $\mathrm{AlBr}_{3}$ contaminated with KF is melted and electrolyzed. Determine the electrode products and write the overall cell reaction.

Electrolysis of Water and Nonstandard Half-Cell Potentials Before we can analyze the electrolysis products of aqueous salt solutions, we must examine the electrolysis of water itself. Extremely pure water is difficult to electrolyze because very few ions are present to conduct a current. If we add a small amount of a salt that cannot be electrolyzed in water (such as $\mathrm{Na}_{2} \mathrm{SO}_{4}$ ), however, electrolysis proceeds rapidly. A glass electrolytic cell with separated gas compartments is used to keep the $\mathrm{H}_{2}$ and $\mathrm{O}_{2}$ gases from mixing (Figure 21.27). At the anode, water is oxidized as the O.N. of O changes from -2 to 0 :

$$
2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-} \quad E=0.82 \mathrm{~V} \quad \text { [anode; oxidation] }
$$

At the cathode, water is reduced as the O.N. of H changes from +1 to 0 :
$2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(g)+2 \mathrm{OH}^{-}(a q) \quad E=-0.42 \mathrm{~V} \quad$ [cathode; reduction]
Doubling the cathode half-reaction to equate $\mathrm{e}^{-}$loss and gain, adding the halfreactions (which involves combining the $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$into $\mathrm{H}_{2} \mathrm{O}$ and canceling $\mathrm{e}^{-}$and excess $\mathrm{H}_{2} \mathrm{O}$ ), and calculating $E_{\text {cell }}$ gives the overall reaction:

$$
2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \quad E_{\text {cell }}=-0.42 \mathrm{~V}-0.82 \mathrm{~V}=-1.24 \mathrm{~V} \quad \text { [overall] }
$$

Notice that these electrode potentials are not written with a standard-state symbol (degree sign) because they are not standard electrode potentials. The $\left[\mathrm{H}^{+}\right]$
and $\left[\mathrm{OH}^{-}\right]$are $1.0 \times 10^{-7} \mathrm{M}$ rather than the standard-state value of 1 M . These $E$ values are obtained by applying the Nernst equation. For example, the calculation for the anode potential (with $n=4$ ) is

$$
E_{\text {cell }}=E_{\text {cell }}^{\circ}-\frac{0.0592 \mathrm{~V}}{4} \log \left(P_{\mathrm{O}_{2}} \times\left[\mathrm{H}^{+}\right]^{4}\right)
$$

The standard potential for the oxidation of water is -1.23 V (from Appendix D ) and $P_{\mathrm{O}_{2}} \approx 1 \mathrm{~atm}$ in the half-cell, so we have

$$
E_{\text {cell }}=-1.23 \mathrm{~V}-\left\{\frac{0.0592 \mathrm{~V}}{4} \times\left[\log 1+4 \log \left(1.0 \times 10^{-7}\right)\right]\right\}=-0.82 \mathrm{~V}
$$

In aqueous ionic solutions, $\left[\mathrm{H}^{+}\right]$and $\left[\mathrm{OH}^{-}\right]$are approximately $10^{-7} \mathrm{M}$ also, so we use these nonstandard $E_{\text {cell }}$ values to predict electrode products.

## Electrolysis of Aqueous Salt Solutions and the Phenomenon of Overvoltage

Aqueous salt solutions are mixtures of ions and water, so we have to compare the various electrode potentials to predict the electrode products. When two halfreactions are possible at an electrode,

- The reduction with the less negative (more positive) electrode potential occurs.
- The oxidation with the less positive (more negative) electrode potential occurs.

What happens, for instance, when a solution of potassium iodide is electrolyzed? The possible oxidizing agents are $\mathrm{K}^{+}$and $\mathrm{H}_{2} \mathrm{O}$, and their reduction halfreactions are

$$
\begin{aligned}
\mathrm{K}^{+}(a q)+\mathrm{e}^{-} \longrightarrow \mathrm{K}(s) & E^{\circ} & =-2.93 \mathrm{~V} \\
2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(g)+2 \mathrm{OH}^{-}(a q) & E & =-0.42 \mathrm{~V}
\end{aligned} \quad \text { [reduction] } 0
$$

The less negative electrode potential for water means that it is much easier to reduce than $\mathrm{K}^{+}$, so $\mathrm{H}_{2}$ forms at the cathode. The possible reducing agents are $\mathrm{I}^{-}$ and $\mathrm{H}_{2} \mathrm{O}$, and their oxidation half-ationsafe PD Fnhancer

$$
\begin{array}{rlr}
2 \mathrm{I}^{-}(a q) \longrightarrow \mathrm{I}_{2}(s)+2 \mathrm{e}^{-} & E^{\circ}=0.53 \mathrm{~V} & \text { [oxidation] } \\
2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-} & E=0.82 \mathrm{~V}
\end{array}
$$

The less positive electrode potential for $\mathrm{I}^{-}$means that a lower potential is needed to oxidize it than to oxidize $\mathrm{H}_{2} \mathrm{O}$, so $\mathrm{I}_{2}$ forms at the anode.

However, the products predicted from this type of comparison of electrode potentials are not always the actual products. For gases such as $\mathrm{H}_{2}(g)$ and $\mathrm{O}_{2}(g)$ to be produced at metal electrodes, an additional voltage is required. This increment above the expected voltage is called the overvoltage, and it is 0.4 to 0.6 V for these gases. The overvoltage results from kinetic factors, such as the large activation energy (Section 16.5) required for gases to form at the electrode.

Overvoltage has major practical significance. A multibillion-dollar example is the industrial production of chlorine from concentrated NaCl solution. Water is easier to reduce than $\mathrm{Na}^{+}$, so $\mathrm{H}_{2}$ forms at the cathode, even with an overvoltage of 0.6 V :

$$
\begin{array}{cl}
\mathrm{Na}^{+}(a q)+\mathrm{e}^{-} \longrightarrow \mathrm{Na}(s) & E^{\circ}=-2.71 \mathrm{~V} \\
2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(g)+2 \mathrm{OH}^{-}(a q) & E=-0.42 \mathrm{~V}(\approx-1 \mathrm{~V} \text { with overvoltage })
\end{array}
$$

[reduction]
But $\mathrm{Cl}_{2}$ does form at the anode, even though the electrode potentials themselves would lead us to predict that $\mathrm{O}_{2}$ should form:

$$
\begin{array}{rlrl}
2 \mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow \mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-} & E & =0.82 \mathrm{~V}(\sim 1.4 \mathrm{~V} \text { with overvoltage) } \\
2 \mathrm{Cl}^{-}(a q) & \mathrm{Cl}_{2}(g)+2 \mathrm{e}^{-} & =1.36 \mathrm{~V} \quad \text { [oxidation] }
\end{array}
$$

An overvoltage of $\sim 0.6 \mathrm{~V}$ makes the potential needed to form $\mathrm{O}_{2}$ slightly above that for $\mathrm{Cl}_{2}$. Keeping the $\left[\mathrm{Cl}^{-}\right]$high also favors $\mathrm{Cl}_{2}$ formation. Thus, chlorine, which is one of the 10 most heavily produced industrial chemicals, can be formed from plentiful natural sources of aqueous sodium chloride (see Chapter 22).

Electrolysis of aqueous KBr .

From these and other examples, we can determine which elements can be prepared electrolytically from aqueous solutions of their salts:

1. Cations of less active metals are reduced to the metal, including gold, silver, copper, chromium, platinum, and cadmium.
2. Cations of more active metals are not reduced, including those in Groups 1A(1) and $2 \mathrm{~A}(2)$, and Al from $3 \mathrm{~A}(13)$. Water is reduced to $\mathrm{H}_{2}$ and $\mathrm{OH}^{-}$instead.
3. Anions that are oxidized, because of overvoltage from $\mathrm{O}_{2}$ formation, include the halides ( $\left[\mathrm{Cl}^{-}\right]$must be high), except for $\mathrm{F}^{-}$.
4. Anions that are not oxidized include $\mathrm{F}^{-}$and common oxoanions, such as $\mathrm{SO}_{4}{ }^{2-}, \mathrm{CO}_{3}{ }^{2-}, \mathrm{NO}_{3}{ }^{-}$, and $\mathrm{PO}_{4}{ }^{3-}$, because the central nonmetal in these oxoanions is already in its highest oxidation state. Water is oxidized to $\mathrm{O}_{2}$ and $\mathrm{H}^{+}$instead.

SAMPLE PROBLEM 21.9 Predicting the Electrolysis Products of Aqueous Salt Solutions
PROBLEM What products form during electrolysis of aqueous solutions of the following salts: (a) KBr ; (b) $\mathrm{AgNO}_{3}$; (c) $\mathrm{MgSO}_{4}$ ?
PLAN We identify the reacting ions and compare their electrode potentials with those of water, taking the 0.4 to 0.6 V overvoltage into consideration. The reduction half-reaction with the less negative electrode potential occurs at the cathode, and the oxidation halfreaction with the less positive electrode potential occurs at the anode.
SOLUTION
(a)

$$
\begin{aligned}
\mathrm{K}^{+}(a q)+\mathrm{e}^{-} \longrightarrow \mathrm{K}(s) & E^{\circ} & =-2.93 \mathrm{~V} \\
2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(g)+2 \mathrm{OH}^{-}(a q) & E & =-0.42 \mathrm{~V}
\end{aligned}
$$

Despite the overvoltage, which makes $E$ for the reduction of water between -0.8 and $-1.0 \mathrm{~V}, \mathrm{H}_{2} \mathrm{O}$ is still easier to reduce than $\mathrm{K}^{+}$, so $\mathrm{H}_{2}(g)$ forms at the cathode.

$$
\begin{aligned}
2 \mathrm{Br}^{-}(a q) & \mathrm{Br}_{2}(l)+2 \mathrm{e}^{-} & =1.07 \mathrm{~V} \\
2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-} & E & =0.82 \mathrm{~V}
\end{aligned}
$$

Because of the overvoltage, which makes $E$ for the oxidation of water between 1.2 and $1.4 \mathrm{~V}, \mathrm{Br}^{-}$is easier to oxidize than water, so $\mathrm{Br}_{2}(l)$ forms at the anode (see photo).
(b)

$$
\begin{aligned}
\mathrm{Ag}^{+}(a q)+\mathrm{e}^{-} \longrightarrow \mathrm{Ag}(s) & E^{\circ} & =0.80 \mathrm{~V} \\
2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(g)+2 \mathrm{OH}^{-}(a q) & E & =-0.42 \mathrm{~V}
\end{aligned}
$$

As the cation of an inactive metal, $\mathrm{Ag}^{+}$is a better oxidizing agent than $\mathrm{H}_{2} \mathrm{O}$, so $\mathrm{Ag}(s)$ forms at the cathode. $\mathrm{NO}_{3}{ }^{-}$cannot be oxidized, because N is already in its highest $(+5)$ oxidation state. Thus, $\mathrm{O}_{2}(g)$ forms at the anode:
(c)

$$
\begin{aligned}
2 \mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow \mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-} \\
\mathrm{Mg}^{2+}(a q)+2 \mathrm{e}^{-} & \longrightarrow \mathrm{Mg}(s) \quad E^{\circ}=-2.37 \mathrm{~V}
\end{aligned}
$$

Like $\mathrm{K}^{+}$in part (a), $\mathrm{Mg}^{2+}$ cannot be reduced in the presence of water, so $\mathrm{H}_{2}(g)$ forms at the cathode. The $\mathrm{SO}_{4}{ }^{2-}$ ion cannot be oxidized because S is in its highest $(+6)$ oxidation state. Thus, $\mathrm{H}_{2} \mathrm{O}$ is oxidized, and $\mathrm{O}_{2}(g)$ forms at the anode:

$$
2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-}
$$

FOLLOW-UP PROBLEM 21.9 Write half-reactions showing the products you predict will form in the electrolysis of aqueous $\mathrm{AuBr}_{3}$.

## The Stoichiometry of Electrolysis: The Relation Between Amounts of Charge and Product

As you've seen, the charge flowing through an electrolytic cell yields products at the electrodes. In the electrolysis of molten NaCl , for example, the power source supplies electrons to the cathode, where $\mathrm{Na}^{+}$ions migrate to pick them up and
become Na metal. At the same time, the power source pulls from the anode the electrons that $\mathrm{Cl}^{-}$ions release as they become $\mathrm{Cl}_{2}$ gas. It follows that the more electrons picked up by $\mathrm{Na}^{+}$ions and released by $\mathrm{Cl}^{-}$ions, the greater the amounts of Na and $\mathrm{Cl}_{2}$ that form. This relationship was first determined experimentally by Michael Faraday and is referred to as Faraday's law of electrolysis: the amount of substance produced at each electrode is directly proportional to the quantity of charge flowing through the cell.

Each balanced half-reaction shows the amounts (mol) of reactant, electrons, and product involved in the change, so it contains the information we need to answer such questions as "How much material will form as a result of a given quantity of charge?" or, conversely, "How much charge is needed to produce a given amount of material?" To apply Faraday's law,

1. Balance the half-reaction to find the number of moles of electrons needed per mole of product.
2. Use the Faraday constant ( $F=9.65 \times 10^{4} \mathrm{C} / \mathrm{mol} \mathrm{e}^{-}$) to find the corresponding charge.
3. Use the molar mass to find the charge needed for a given mass of product.

In practice, to supply the correct amount of electricity, we need some means of finding the charge flowing through the cell. We cannot measure charge directly, but we can measure current, the charge flowing per unit time. The SI unit of current is the ampere (A), which is defined as a charge of 1 coulomb flowing through a conductor in 1 second:

$$
\begin{equation*}
1 \text { ampere }=1 \text { coulomb/second } \quad \text { or } \quad 1 \mathrm{~A}=1 \mathrm{C} / \mathrm{s} \tag{21.11}
\end{equation*}
$$

Thus, the current multiplied by the time gives the charge:

Therefore, we find the charge by measuring the current and the time during which the current flows. This, in turn, relates to the amount of product formed. Figure 21.28 summarizes these relationships.

The Father of Electrochemistry and Much More The investigations by Michael Faraday (1791-1867) into the mass of an element that is equivalent to a given amount of charge established electrochemistry as a quantitative science, but his breakthroughs in physics are even more celebrated. In 1821, Faraday developed the precursor of the electric motor, and his later studies of currents induced by electric and magnetic fields eventually led to the electric generator and the transformer. After his death, this self-educated blacksmith's son was rated by Albert Einstein as the peer of Newton, Galileo, and Maxwell. He is shown here delivering one of his famous lectures, "Chemical History of a Candle."

Problems based on Faraday's law often ask you to calculate current, mass of material, or time. The electrode half-reaction provides the key to solving these problems because it is related to the mass for a certain quantity of charge.

As an example, let's consider a typical problem in practical electrolysis: how long does it take to produce 3.0 g of $\mathrm{Cl}_{2}(\mathrm{~g})$ by electrolysis of aqueous NaCl using a power supply with a current of 12 A ? The problem asks for the time needed to produce a certain mass, so let's first relate mass to number of moles of electrons to find the charge needed. Then, we'll relate the charge to the current to find the time.

We know the mass of $\mathrm{Cl}_{2}$ produced, so we can find the amount (mol) of $\mathrm{Cl}_{2}$. The half-reaction tells us that the loss of 2 mol of electrons produces 1 mol of chlorine gas:

$$
2 \mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{Cl}_{2}(g)+2 \mathrm{e}^{-}
$$

Figure 21.28 A summary diagram for the stoichiometry of electrolysis.

We use this relationship as a conversion factor, and multiplying by the Faraday constant gives us the total charge:

$$
\text { Charge }(\mathrm{C})=3.0 \mathrm{~g} \mathrm{Cl}_{2} \times \frac{1 \mathrm{~mol} \mathrm{Cl}_{2}}{70.90 \mathrm{~g} \mathrm{Cl}_{2}} \times \frac{2 \mathrm{~mol} \mathrm{e}^{-}}{1 \mathrm{~mol} \mathrm{Cl}_{2}} \times \frac{9.65 \times 10^{4} \mathrm{C}}{1 \mathrm{~mol} \mathrm{e}^{-}}=8.2 \times 10^{3} \mathrm{C}
$$

Now we use the relationship between charge and current to find the time needed:

$$
\text { Time }(\mathrm{s})=\frac{\text { charge }(\mathrm{C})}{\operatorname{current}(\mathrm{A}, \text { or } \mathrm{C} / \mathrm{s})}=8.2 \times 10^{3} \mathrm{C} \times \frac{1 \mathrm{~s}}{12 \mathrm{C}}=6.8 \times 10^{2} \mathrm{~s}(\sim 11 \mathrm{~min})
$$

Note that the entire calculation follows Figure 21.28 until the last step:
grams of $\mathrm{Cl}_{2} \Rightarrow$ moles of $\mathrm{Cl}_{2} \Rightarrow$ moles of $\mathrm{e}^{-} \Rightarrow$ coulombs $\Rightarrow$ seconds
Sample Problem 21.10 demonstrates the steps as they appear in Figure 21.28.

## SAMPLE PROBLEM 21.10 Applying the Relationship Among Current, Time, and Amount of Substance

PROBLEM A technician is plating a faucet with 0.86 g of chromium from an electrolytic bath containing aqueous $\mathrm{Cr}_{2}\left(\mathrm{SO}_{4}\right)_{3}$. If 12.5 min is allowed for the plating, what current is needed?
PLAN To find the current, we divide the charge by the time; therefore, we need to find the charge. First, we write the half-reaction for $\mathrm{Cr}^{3+}$ reduction. From it, we know the number of moles of $\mathrm{e}^{-}$required per mole of Cr . As the roadmap shows, to find the charge, we convert the mass of Cr needed ( 0.86 g ) to amount (mol) of Cr . The balanced halfreaction gives the amount (mol) of $\mathrm{e}^{-}$transferred. Then, we use the Faraday constant $\left(9.65 \times 10^{4} \mathrm{C} / \mathrm{mol}^{-}\right)$to find the charge and divide by the time ( 12.5 min , converted to seconds) to obtain the current.
SOLUTION Writing the balanced half-reaction:

$$
\mathrm{Cr}^{3+}(a q)+3 \mathrm{e}^{-} \longrightarrow \mathrm{Cr}(s)
$$

Combining steps to find amount (mol) of $\mathrm{e}^{-}$transferred for mass of Cr needed:

$$
\text { Moles of } \mathrm{e}^{-} \text {transferred }=0.86 \mathrm{~g} \mathrm{Cr} \times \frac{1 \mathrm{~mol} \mathrm{Cr}}{52.00 \mathrm{~g} \mathrm{Cr}} \times \frac{3 \mathrm{~mol} \mathrm{e}^{-}}{1 \mathrm{~mol} \mathrm{Cr}}=0.050 \mathrm{~mol} \mathrm{e}^{-}
$$

Calculating the charge:

$$
\text { Charge }(\mathrm{C})=0.050 \mathrm{~mol} \mathrm{e} ~=\frac{9.65 \times 10^{4} \mathrm{C}}{1 \mathrm{~mol} \mathrm{e}^{-}}=4.8 \times 10^{3} \mathrm{C}
$$

Calculating the current:

$$
\text { Current }(\mathrm{A})=\frac{\text { charge }(\mathrm{C})}{\text { time }(\mathrm{s})}=\frac{4.8 \times 10^{3} \mathrm{C}}{12.5 \mathrm{~min}} \times \frac{1 \mathrm{~min}}{60 \mathrm{~s}}=6.4 \mathrm{C} / \mathrm{s}=6.4 \mathrm{~A}
$$

CHECK Rounding gives

$$
(\sim 0.9 \mathrm{~g})(1 \mathrm{~mol} \mathrm{Cr} / 50 \mathrm{~g})(3 \mathrm{~mol} \mathrm{e}-11 \mathrm{~mol} \mathrm{Cr})=5 \times 10^{-2} \mathrm{~mol} \mathrm{e}^{-}
$$

then $\quad\left(5 \times 10^{-2} \mathrm{~mol} \mathrm{e}^{-}\right)\left(\sim 1 \times 10^{5} \mathrm{C} / \mathrm{mol} \mathrm{e}^{-}\right)=5 \times 10^{3} \mathrm{C}$
and

$$
\left(5 \times 10^{3} \mathrm{C} / 12 \mathrm{~min}\right)(1 \mathrm{~min} / 60 \mathrm{~s})=7 \mathrm{~A}
$$

COMMENT For the sake of introducing Faraday's law, the details of the electroplating process have been simplified here. Actually, electroplating chromium is only $30 \%$ to $40 \%$ efficient and must be run at a particular temperature range for the plate to appear bright. Nearly 10,000 metric tons $\left(2 \times 10^{8} \mathrm{~mol}\right)$ of chromium is used annually for electroplating.
FOLLOW-UP PROBLEM 21.10 Using a current of 4.75 A , how many minutes does it take to plate onto a sculpture 1.50 g of Cu from a $\mathrm{CuSO}_{4}$ solution?

The following Chemical Connections essay links several themes of this chapter in the setting of a living cell.

## Chemical Connections to Biological Energetics <br> Cellular Electrochemistry and the Production of ATP

Biological cells apply the principles of electrochemical cells to generate energy. The complex multistep process can be divided into two parts:

1. Bond energy in food is used to generate an electrochemical potential.
2. The potential is used to create the bond energy of the highenergy molecule adenosine triphosphate (ATP; see Chemical Connections, pp. 908-909).

The redox species that accomplish these steps are part of the electron-transport chain (ETC), which lies on the inner membranes of mitochondria, the subcellular particles that produce the cell's energy (Figure B21.1).

The ETC is a series of large molecules (mostly proteins), each of which contains a redox couple (the oxidized and reduced forms of a species), such as $\mathrm{Fe}^{3+} / \mathrm{Fe}^{2+}$, that passes electrons down the chain. At three points along the chain, large potential differences supply enough free energy to convert adenosine diphosphate (ADP) into ATP.

## Bond Energy to Electrochemical Potential

Cells utilize the energy in food by releasing it in controlled steps rather than all at once. The reaction that ultimately powers the ETC is the oxidation of hydrogen to form water:

$$
\mathrm{H}_{2}+\frac{1}{2} \mathrm{O}_{2} \longrightarrow \mathrm{H}_{2} \mathrm{O}
$$

However, instead of $\mathrm{H}_{2}$ gas, which doestoracuiq organsis, the hydrogen takes the form of two $\mathrm{H}^{+}$ions and two $\mathrm{e}^{-}$. A bio-
logical oxidizing agent called $\mathrm{NAD}^{+}$(nicotinamide adenine dinucleotide) acquires these protons and electrons in the process of oxidizing the molecules in food. To show this process, we use the following half-reaction (without canceling an $\mathrm{H}^{+}$on both sides):

$$
\mathrm{NAD}^{+}(a q)+2 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{NADH}(a q)+\mathrm{H}^{+}(a q)
$$

At the mitochondrial inner membrane, the NADH and $\mathrm{H}^{+}$transfer the two $\mathrm{e}^{-}$to the first redox couple of the ETC and release the two $\mathrm{H}^{+}$. The electrons are transported down the chain of redox couples, where they finally reduce $\mathrm{O}_{2}$ to $\mathrm{H}_{2} \mathrm{O}$. The overall process, with standard electrode potentials,* is

Thus, for each mole of NADH that enters the ETC, the freeenergy equivalent of 1.14 V is available:

$$
\begin{aligned}
\Delta G^{\circ \prime} & =-n F E^{\circ \prime} \\
& =-(2 \mathrm{~mol} \mathrm{e} \\
& =-\mathrm{mol} \mathrm{NADH})\left(96.5 \mathrm{~kJ} / \mathrm{V} \cdot \mathrm{~mol} \mathrm{e}^{-}\right)(1.130 \mathrm{~V}) \\
& =-218 \mathrm{~kJ} / \mathrm{mol} \mathrm{NADH}
\end{aligned}
$$

(continued)

## Fantiorgical systems, standard potentials are designated $E^{\circ \prime}$ and the standard states include a pH of $7.0\left(\left[\mathrm{H}^{+}\right]=1 \times 10^{-7} \mathrm{M}\right)$.

Figure B21.1 The mitochondrion. A, Mitochondria are subcellular particles outside the cell nucleus. B, They have a smooth outer membrane and a highly folded inner membrane, shown schematically and
in an electron micrograph. C, The components of the electron-transport chain are attached to the inner membrane.

Note that this aspect of the process functions like a voltaic cell: a spontaneous reaction, the reduction of $\mathrm{O}_{2}$ to $\mathrm{H}_{2} \mathrm{O}$, is used to generate a potential. In contrast to a laboratory voltaic cell, in which the overall process occurs in one step, this process occurs in many small steps. Figure B21.2 is a greatly simplified diagram of the three key steps in the ETC that generate the high potential to produce ATP.

In the cell, each of these steps is part of a complex consisting of several components, most of which are proteins. Electrons are passed from one redox couple to the next down the chain, such that the reduced form of the first couple reduces the oxidized form of the second, and so forth. Most of the ETC components are ironcontaining proteins, and the redox change consists of the oxidation of $\mathrm{Fe}^{2+}$ to $\mathrm{Fe}^{3+}$ in one component accompanied by the reduction of $\mathrm{Fe}^{3+}$ to $\mathrm{Fe}^{2+}$ in another:

$$
\mathrm{Fe}^{2+}(\text { in } \mathrm{A})+\mathrm{Fe}^{3+}(\text { in } \mathrm{B}) \longrightarrow \mathrm{Fe}^{3+}(\text { in } \mathrm{A})+\mathrm{Fe}^{2+}(\text { in } \mathrm{B})
$$

In other words, metal ions within the ETC proteins are the actual species undergoing the redox reactions.

## Electrochemical Potential to Bond Energy

At the three points shown in Figure B21.2, the large potential difference is used to form ATP:

$$
\begin{array}{r}
\mathrm{ADP}^{3-}(a q)+\mathrm{HPO}_{4}^{2-}(a q)+\mathrm{H}^{+}(a q) \longrightarrow \operatorname{ATP}^{4-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \\
\Delta G^{\circ \prime}=30.5 \mathrm{~kJ} / \mathrm{mol}
\end{array}
$$

Note that the free energy that is released at each of the three ATP-producing points exceeds 30.5 kJ , the free energy that must be absorbed to form ATP. Thus, just as in aneterficell, an electrochemical potential is supplied to drive a nonspontaneous reaction.

So far, we've followed the flow of electrons through the members of the ETC, but where have the released protons gone? The answer is the key to how electrochemical potential is converted to bond energy in ATP. As the electrons flow and the redox couples change oxidation states, free energy released at the three key steps is used to force $\mathrm{H}^{+}$ions into the intermembrane space, so that the $\left[\mathrm{H}^{+}\right]$of the intermembrane space soon becomes higher than that of the matrix (Figure B21.3). In other words, this aspect of the process acts as an electrolytic cell by using the free energy supplied by the three steps to create what amounts to an $\mathrm{H}^{+}$concentration cell across the membrane.

When the $\left[\mathrm{H}^{+}\right]$difference across the membrane reaches about 2.5 -fold, it triggers the membrane to let $\mathrm{H}^{+}$ions flow back through spontaneously (in effect, closing the switch and allowing the concentration cell to operate). The free energy released in this spontaneous process drives the nonspontaneous ATP formation via a mechanism that is catalyzed by the enzyme ATP synthase. (Paul D. Boyer and John E. Walker shared half of the 1997 Nobel Prize in chemistry for elucidating this mechanism.)

Thus, the mitochondrion uses the "electron-motive force" of redox couples on the membrane to generate a "proton-motive force" across the membrane, which converts a potential difference to bond energy.

Figure B21.2 The main energy-yielding steps in the electrontransport chain (ETC). The electron carriers in the ETC undergo oxidation and reduction as they pass electrons to one another along the chain. At the three points shown, the difference in potential $E^{\circ \prime}$ (or free energy, $\Delta G^{\circ \prime}$ ) is large enough to be used for ATP production. (A complex consists of many components, mostly proteins; $Q$ is a large organic molecule; and Cyt is the abbreviation for a cytochrome, a protein that contains a metal-ion redox couple, such as $\mathrm{Fe}^{3+} / \mathrm{Fe}^{2+}$, which is the actual electron carrier.)

## Enhancer

Figure B21.3 Coupling electron transport to proton transport to ATP synthesis. The purpose of the ETC is to convert the free energy released from food molecules into the stored free energy of ATP. It accomplishes this by transporting electrons along the chain (curved yellow line), while protons are pumped out of the mitochondrial matrix. This pumping creates an $\left[\mathrm{H}^{+}\right]$difference and generates a potential across the inner membrane (in effect, a concentration cell). When this potential reaches a "trigger" value, $\mathrm{H}^{+}$flows back into the inner space, and the free energy released drives the formation of ATP.

## Section Summary

An electrolytic cell uses electrical energy to drive a nonspontaneous reaction. - Oxidation occurs at the anode and reduction at the cathode, but the direction of electron flow and the charges of the electrodes are opposite those in voltaic cells. - When two products can form at each electrode, the more easily oxidized substance reacts at the anode and the more easily reduced at the cathode. - The reduction or oxidation of water takes place at nonstandard conditions. - Overvoltage causes the actual voltage required to be unexpectedly high and can affect the electrode product that forms. - The amount of product that forms depends on the quantity of charge flowing through the cell, which is related to the magnitude of the current and the time it flows. - Biological redox systems combine aspects of voltaic, concentration, and electrolytic cells to convert bond energy in food into electrochemical potential and then into the bond energy of ATP.

## Chapter Perspective

The field of electrochemistry is one of the many areas in which the principles of thermodynamics lead to practical benefits. As you've seen, electrochemical cells can use a reaction to generate energy or use energy to drive a reaction. Such processes are central not only to our mobile way of life, but also to our biological existence. In Chapter 22, we examine the electrochemical (and other) methods used by industry to convert raw natural resources into some of the materials modern society finds indispensable.

## CHAPTER REVIEW GUIDE

## Learning Objectives These are concepts andsskils you should know after studying this chapter.

Relevant section and/or sample problem (SP) numbers appear in parentheses.

## Understand These Concepts

1. The meanings of oxidation and reduction; why an oxidizing agent is reduced and a reducing agent is oxidized (Section 21.1; also Section 4.5)
2. How the half-reaction method is used to balance redox reactions in acidic or basic solution (Section 21.1)
3. The distinction between voltaic and electrolytic cells in terms of the sign of $\Delta G$ (Section 21.1)
4. How voltaic cells use a spontaneous reaction to release electrical energy (Section 21.2)
5. The physical makeup of a voltaic cell: arrangement and composition of half-cells, relative charges of electrodes, and purpose of a salt bridge (Section 21.2)
6. How the difference in reducing strength of the electrodes determines the direction of electron flow (Section 21.2)
7. The correspondence between a positive $E_{\text {cell }}$ and a spontaneous cell reaction (Section 21.3)
8. The usefulness and significance of standard electrode potentials ( $E_{\text {half-cell }}^{\circ}$ ) (Section 21.3)
9. How $E_{\text {half-cell }}^{\circ}$ values are combined to give $E_{\text {cell }}^{\circ}$ (Section 21.3) 10. How the standard reference electrode is used to find an unknown $E_{\text {half-cell }}^{\circ}$ (Section 21.3)
10. How an emf series (e.g., Table 21.2 or Appendix D) is used to write spontaneous redox reactions (Section 21.3)
11. How the relative reactivity of a metal is determined by its reducing power and is related to the negative of its $E_{\text {half-cell }}^{\circ}$ (Section 21.3)
12. How $E_{\text {cell }}$ (the nonstandard cell potential) is related to $\Delta G$ (maximum work) and the charge (moles of electrons times the Faraday constant) flowing through the cell (Section 21.4)
13. The interrelationship of $\Delta G^{\circ}, E_{\text {cell }}^{\circ}$, and $K$ (Section 21.4)

15 . How $E_{\text {cell }}$ changes as the cell operates ( $Q$ changes) (Section 21.4)
16. Why a voltaic cell can do work until $Q=K$ (Section 21.4)
17. How a concentration cell does work until the half-cell concentrations are equal (Section 21.4)
18. The distinction between primary (nonrechargeable) and secondary (rechargeable) batteries and the nature of fuel cells (Section 21.5)
19. How corrosion occurs and is prevented; the similarities between a corroding metal and a voltaic cell (Section 21.6)
20. How electrolytic cells use nonspontaneous redox reactions driven by an external source of electricity (Section 21.7)
21. How atomic properties (ionization energy and electronegativity) determine the products of the electrolysis of molten salt mixtures (Section 21.7)
22. How the electrolysis of water influences the products of aqueous electrolysis; the importance of overvoltage (Section 21.7) 23. The relationship between the quantity of charge flowing through the cell and the amount of product formed (Section 21.7)

## Learning Objectives (continued)

## Master These Skills

1. Balancing redox reactions by the half-reaction method (Section 21.1 and SP 21.1)
2. Diagramming and notating a voltaic cell (Section 21.2 and SP 21.2)
3. Combining $E_{\text {half-cell }}^{\circ}$ values to obtain $E_{\text {cell }}^{\circ}$ (Section 21.3)
4. Using $E_{\text {cell }}^{\circ}$ and a known $E_{\text {half-cell }}^{\circ}$ to find an unknown $E_{\text {half-cell }}^{\circ}$ (SP 21.3)
5. Manipulating half-reactions to write a spontaneous redox reaction and calculate its $E_{\text {cell }}^{\circ}$ (SP 21.4)
6. Ranking the relative strengths of oxidizing and reducing agents in a redox reaction (SP 21.4)
7. Predicting whether a metal can displace hydrogen or another metal from solution (Section 21.3)
8. Using the interrelationship of $\Delta G^{\circ}, E_{\text {cell }}^{\circ}$, and $K$ to calculate one of the three given the other two (Section 21.4 and SP 21.5)
9. Using the Nernst equation to calculate the nonstandard cell potential ( $E_{\text {cell }}$ ) (SP 21.6)
10. Calculating $E_{\text {cell }}$ of a concentration cell (SP 21.7)
11. Predicting the products of the electrolysis of a mixture of molten salts (SP 21.8)
12. Predicting the products of the electrolysis of aqueous salt solutions (SP 21.9)
13. Calculating the current (or time) needed to produce a given amount of product by electrolysis (SP 21.10)

Key Terms These important terms appear in boldface in the chapter and are defined again in the Glossary.
electrochemistry (923)
electrochemical cell (923)

## Section 21.1

half-reaction method (924)
voltaic (galvanic) cell (928)
electrolytic cell (928)
electrode (928)
electrolyte (928)
anode (929)
cathode (929)

## Section 21.2

half-cell (930)
salt bridge (930)
Section 21.3
cell potential ( $E_{\text {cell }}$ ) (934)
voltage (934)
electromotive force (emf) (934)
volt (V) (934)
coulomb (C) 939 ) 90
standard cell potential $\left(E_{\text {cell }}^{\circ}\right)$ (935)
standard electrode (half-cell) potential ( $E_{\text {half-cell }}^{\circ}$ ) (935)
standard reference half-cell (standard hydrogen electrode) (936)

## Section 21.4

PDF Faraday constant (F) (943)

## Section 21.5

battery (952)
fuel cell (955)
Section 21.6
corrosion (956)

## Section 21.7

electrolysis (961)
overvoltage (963)
ampere (A) (965)

Key Equations and Relationships Numbered and screened concepts are listed for you to refer to or memorize.
21.1 Relating a spontaneous process to the sign of the cell potential (934):

$$
E_{\text {cell }}>0 \text { for a spontaneous process }
$$

21.2 Relating electric potential to energy and charge in SI units (934):

$$
\text { Potential }=\text { energy/charge } \quad \text { or } \quad 1 \mathrm{~V}=1 \mathrm{~J} / \mathrm{C}
$$

21.3 Relating standard cell potential to standard electrode potentials in a voltaic cell (935):

$$
E_{\mathrm{cell}}^{\circ}=E_{\mathrm{cathode}(\text { reduction })}^{\circ}-E_{\text {anode (oxidation) }}^{\circ}
$$

21.4 Defining the Faraday constant (944):

$$
F=9.65 \times 10^{4} \frac{\mathrm{~J}}{\mathrm{~V} \cdot \mathrm{~mol} \mathrm{e}^{-}} \quad(3 \mathrm{sf})
$$

21.5 Relating the free energy change to the cell potential (944):

$$
\Delta G=-n F E_{\text {cell }}
$$

21.6 Finding the standard free energy change from the standard cell potential (944):

$$
\Delta G^{\circ}=-n F E_{\mathrm{cell}}^{\circ}
$$

21.7 Finding the equilibrium constant from the standard cell potential (944):

$$
E_{\text {cell }}^{\circ}=\frac{R T}{n F} \ln K
$$

21.8 Substituting known values of $R, F$, and $T$ into Equation 21.7 and converting to common logarithms (945):

$$
\left.E_{\mathrm{cell}}^{\circ}=\frac{0.0592 \mathrm{~V}}{n} \log K \quad \text { or } \quad \log K=\frac{n E_{\mathrm{cell}}^{\circ}}{0.0592 \mathrm{~V}} \quad \text { (at } 298.15 \mathrm{~K}\right)
$$

21.9 Calculating the nonstandard cell potential (Nernst equation) (946):

$$
E_{\mathrm{cell}}=E_{\mathrm{cell}}^{\circ}-\frac{R T}{n F} \ln Q
$$

21.10 Substituting known values of $R, F$, and $T$ into the Nernst equation and converting to common logarithms (946):

$$
E_{\text {cell }}=E_{\text {cell }}^{\circ}-\frac{0.0592 \mathrm{~V}}{n} \log Q \quad(\text { at } 298.15 \mathrm{~K})
$$

21.11 Relating current to charge and time (965):

$$
\text { Current }=\text { charge } / \text { time } \quad \text { or } \quad 1 \mathrm{~A}=1 \mathrm{C} / \mathrm{s}
$$

## Highlighted Figures and Tables These figures (F) and tables (T) provide a visual review of key ideas.

F21.1 Summary of redox terminology (924)
F21.3 Voltaic and electrolytic cells (928)
F21.5 A voltaic cell based on the zinc-copper reaction (931)
F21.10 The interrelationship of $\Delta G^{\circ}, E_{\text {cell }}^{\circ}$, and $K$ (944)
F21.11 $E_{\text {cell }}$ and $\log Q$ for the zinc-copper cell (948)

F21.21 The corrosion of iron (957)
F21.25 Tin-copper reaction in voltaic and electrolytic cells (959)
T21.4 Comparison of voltaic and electrolytic cells (961)
F21.28 Summary of the stoichiometry of electrolysis (965)

Brief Solutions to FOLLOW-UP PROBLEMS Compare your solutions to these calculation steps and answers.

$$
\begin{aligned}
& 21.16 \mathrm{KMnO}_{4}(a q)+\underset{\mathrm{KOH}(a q)+}{6 \mathrm{~K}_{2} \mathrm{MnO}_{4}(a q)}+\underset{\mathrm{KIO}}{3}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
$$

21.2

$$
\mathrm{Sn}(s) \longrightarrow \mathrm{Sn}^{2+}(a q)+2 \mathrm{e}^{-}
$$

[anode; oxidation]
$6 \mathrm{e}^{-}+14 \mathrm{H}^{+}(a q)+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q) \longrightarrow 2 \mathrm{Cr}^{3+}(a q)+7 \mathrm{H}_{2} \mathrm{O}(l)$
[cathode; reduction]
$3 \mathrm{Sn}(s)+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+14 \mathrm{H}^{+}(a q) \longrightarrow$
$3 \mathrm{Sn}^{2+}(a q)+2 \mathrm{Cr}^{3+}(a q)+7 \mathrm{H}_{2} \mathrm{O}(l) \quad[$ overall $]$
Cell notation:
$\mathrm{Sn}(s)\left|\mathrm{Sn}^{2+}(a q) \| \mathrm{H}^{+}(a q), \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q), \mathrm{Cr}^{3+}(a q)\right|$ graphite

$21.3 \mathrm{Br}_{2}(a q)+2 \mathrm{e}^{-} \longrightarrow 2 \mathrm{Br}^{-}(a q) \quad E_{\text {bromine }}^{\circ}=1.07 \mathrm{~V}$
[cathode]

$$
\begin{array}{r}
2 \mathrm{~V}^{3+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{VO}^{2+}(a q)+4 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} \\
E_{\text {vanadium }}^{\circ}=? \quad[\text { anode }]
\end{array}
$$

$E_{\text {vanadium }}^{\circ}=E_{\text {bromine }}^{\circ}-E_{\text {cell }}^{\circ}=1.07 \mathrm{~V}-1.39 \mathrm{~V}=-0.32 \mathrm{~V}$
$21.4 \mathrm{Fe}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Fe}(s) \quad E^{\circ}=-0.44 \mathrm{~V}$

$$
\frac{2\left[\mathrm{Fe}^{2+}(a q) \longrightarrow \mathrm{Fe}^{3+}(a q)+\mathrm{e}^{-}\right] \quad E^{\circ}=0.77 \mathrm{~V}}{3 \mathrm{Fe}^{2+}(a q) \longrightarrow 2 \mathrm{Fe}^{3+}(a q)+\mathrm{Fe}(s)}
$$

$E_{\text {cell }}^{\circ}=-0.44 \mathrm{~V}-0.77 \mathrm{~V}=-1.21 \mathrm{~V}$
The reaction is nonspontaneous. The spontaneous reaction is
$2 \mathrm{Fe}^{3+}(a q)+\mathrm{Fe}(s) \longrightarrow 3 \mathrm{Fe}^{2+}(a q) \quad E_{\text {cell }}^{\circ}=1.21 \mathrm{~V}$
$\mathrm{Fe}>\mathrm{Fe}^{2+}>\mathrm{Fe}^{3+}$
$21.5 \mathrm{Cd}(s)+\mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{Cd}^{2+}(a q)+\mathrm{Cu}(s)$
$\Delta G^{\circ}=-R T \ln K=-8.314 \mathrm{~J} / \mathrm{mol} \mathrm{rxn} \cdot \mathrm{K} \times 298 \mathrm{~K} \times \ln K$

$$
=-143 \mathrm{~kJ} / \mathrm{mol} \mathrm{rxn} ; K=1.2 \times 10^{25}
$$

$E_{\text {cell }}^{\circ}=\frac{0.0592 \mathrm{~V}}{2} \log \left(1.2 \times 10^{25}\right)=0.742 \mathrm{~V}$

$$
\begin{array}{rlr}
21.6 & \mathrm{Fe}(s) & \longrightarrow \mathrm{Fe}^{2+}(a q)+2 \mathrm{e}^{-} \\
\mathrm{Cu}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu}(s) & E^{\circ}=-0.44 \mathrm{~V} \\
E^{\circ}=0.34 \mathrm{~V} \\
\hline \mathrm{Fe}(s)+\mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{Fe}^{2+}(a q)+\mathrm{Cu}(s) & E_{\text {cell }}^{\circ}=0.78 \mathrm{~V}
\end{array}
$$

$$
\text { So } E_{\text {cell }}=0.78 \mathrm{~V}+0.25 \mathrm{~V}=1.03 \mathrm{~V}
$$

$$
1.03 \mathrm{~V}=0.78 \mathrm{~V}-\frac{0.0592 \mathrm{~V}}{2} \log \frac{\left[\mathrm{Fe}^{2+}\right]}{\left[\mathrm{Cu}^{2+}\right]}
$$

$$
\frac{\left[\mathrm{Fe}^{2+}\right]}{\left[\mathrm{Cu}^{2+}\right]}=3.6 \times 10^{-9}
$$

$$
\left[\mathrm{Fe}^{2+}\right]=3.6 \times 10^{-9} \times 0.30 \mathrm{M}=1.1 \times 10^{-9} \mathrm{M}
$$

$$
21.7 \mathrm{Au}^{3+}\left(a q ; 2.5 \times 10^{-2} M\right)[\mathrm{B}] \longrightarrow \mathrm{Au}^{3+}\left(a q ; 7.0 \times 10^{-4} M\right)[\mathrm{A}]
$$

$$
E_{\text {cell }}=0 \mathrm{~V}-\left(\frac{0.0592 \mathrm{~V}}{3} \times \log \frac{7.0 \times 10^{-4}}{2.5 \times 10^{-2}}\right)=0.0306 \mathrm{~V}
$$

The electrode in A is negative, so it is the anode.
21.8 Oxidizing agents: $\mathrm{K}^{+}$and $\mathrm{Al}^{3+}$.

Reducing agents: $\mathrm{F}^{-}$and $\mathrm{Br}^{-}$.
Al is above and to the right of K in the periodic table, so it has a higher IE:
$\mathrm{Al}^{3+}(l)+3 \mathrm{e}^{-} \longrightarrow \mathrm{Al}(s) \quad$ [cathode; reduction]
Br is below F in Group $7 \mathrm{~A}(17)$, so it has a lower EN :
$2 \mathrm{Br}^{-}(l) \longrightarrow \mathrm{Br}_{2}(g)+2 \mathrm{e}^{-}$
[anode; oxidation]
$2 \mathrm{Al}^{3+}(l)+6 \mathrm{Br}^{-}(l) \longrightarrow 2 \mathrm{Al}(s)+3 \mathrm{Br}_{2}(g) \quad$ [overall]
21.9 The reduction with the more positive electrode potential is $\mathrm{Au}^{3+}(a q)+3 \mathrm{e}^{-} \longrightarrow \mathrm{Au}(s) ; E^{\circ}=1.50 \mathrm{~V}$
[cathode; reduction]
Because of overvoltage, $\mathrm{O}_{2}$ will not form at the anode, so $\mathrm{Br}_{2}$ will form:
$2 \mathrm{Br}^{-}(a q) \longrightarrow \mathrm{Br}_{2}(l)+2 \mathrm{e}^{-} ; E^{\circ}=1.07 \mathrm{~V}$
[cathode; oxidation]
$21.10 \mathrm{Cu}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu}(s)$; therefore,
$2 \mathrm{~mol} \mathrm{e}{ }^{-} / 1 \mathrm{~mol} \mathrm{Cu}=2 \mathrm{~mol} \mathrm{e}{ }^{-} / 63.55 \mathrm{~g} \mathrm{Cu}$
Time $(\mathrm{min})=1.50 \mathrm{~g} \mathrm{Cu} \times \frac{2 \mathrm{~mol} \mathrm{e}^{-}}{63.55 \mathrm{~g} \mathrm{Cu}}$

$$
\begin{aligned}
& \times \frac{9.65 \times 10^{4} \mathrm{C}}{1 \mathrm{~mol} \mathrm{e}^{-}} \times \frac{1 \mathrm{~s}}{4.75 \mathrm{C}} \times \frac{1 \mathrm{~min}}{60 \mathrm{~s}} \\
= & 16.0 \mathrm{~min}
\end{aligned}
$$

## PROBLEMS

Problems with colored numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and provide the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.
Note: Unless stated otherwise, all problems refer to systems at $298 \mathrm{~K}\left(25^{\circ} \mathrm{C}\right)$.

## Redox Reactions and Electrochemical Cells

(Sample Problem 21.1)

## - Concept Review Questions

21.1 Define oxidation and reduction in terms of electron transfer and change in oxidation number.
21.2 Why must an electrochemical process involve a redox reaction?
21.3 Can one half-reaction in a redox process take place independently of the other? Explain.
21.4 Water is used to balance O atoms in the half-reaction method. Why can't $\mathrm{O}^{2-}$ ions be used instead?
21.5 During the redox balancing process, what step is taken to ensure that $\mathrm{e}^{-}$loss equals $\mathrm{e}^{-}$gain?
21.6 How are protons removed when balancing a redox reaction in basic solution?
21.7 Are spectator ions used to balance the halfreation a Pe-DE dox reaction? At what stage might spectator ions enter the balancing process?
21.8 Which type of electrochemical cell has $\Delta G_{\text {sys }}<0$ ? Which type shows an increase in free energy?
21.9 Which statements are true? Correct any that are false.
(a) In a voltaic cell, the anode is negative relative to the cathode.
(b) Oxidation occurs at the anode of a voltaic or electrolytic cell.
(c) Electrons flow into the cathode of an electrolytic cell.
(d) In a voltaic cell, the surroundings do work on the system.
(e) A metal that plates out of an electrolytic cell appears on the cathode.
(f) The cell electrolyte provides a solution of mobile electrons.

- Skill-Building Exercises (grouped in similar pairs)
21.10 Consider the following balanced redox reaction:

$$
\begin{array}{r}
16 \mathrm{H}^{+}(a q)+2 \mathrm{MnO}_{4}^{-}(a q)+10 \mathrm{Cl}^{-}(a q) \longrightarrow \\
2 \mathrm{Mn}^{2+}(a q)+5 \mathrm{Cl}_{2}(g)+8 \mathrm{H}_{2} \mathrm{O}(l)
\end{array}
$$

(a) Which species is being oxidized?
(b) Which species is being reduced?
(c) Which species is the oxidizing agent?
(d) Which species is the reducing agent?
(e) From which species to which does electron transfer occur?
(f) Write the balanced molecular equation, with $\mathrm{K}^{+}$and $\mathrm{SO}_{4}{ }^{2-}$ as the spectator ions.
21.11 Consider the following balanced redox reaction:

$$
2 \mathrm{CrO}_{2}^{-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)+6 \mathrm{ClO}^{-}(a q) \longrightarrow \mathrm{CrO}_{4}^{2-}(a q)+3 \mathrm{Cl}_{2}(g)+4 \mathrm{OH}^{-}(a q)
$$

(a) Which species is being oxidized?
(b) Which species is being reduced?
(c) Which species is the oxidizing agent?
(d) Which species is the reducing agent?
(e) From which species to which does electron transfer occur?
(f) Write the balanced molecular equation, with $\mathrm{Na}^{+}$as the spectator ion.
21.12 Balance the following skeleton reactions and identify the oxidizing and reducing agents:
(a) $\mathrm{ClO}_{3}{ }^{-}(a q)+\mathrm{I}^{-}(a q) \longrightarrow \mathrm{I}_{2}(s)+\mathrm{Cl}^{-}(a q)$ [acidic]
(b) $\mathrm{MnO}_{4}^{-}(a q)+\mathrm{SO}_{3}{ }^{2-}(a q) \longrightarrow$
$\mathrm{MnO}_{2}(s)+\mathrm{SO}_{4}{ }^{2-}(a q)$ [basic]
(c) $\mathrm{MnO}_{4}{ }^{-}(a q)+\mathrm{H}_{2} \mathrm{O}_{2}(a q) \longrightarrow \mathrm{Mn}^{2+}(a q)+\mathrm{O}_{2}(g)$ [acidic]
21.13 Balance the following skeleton reactions and identify the oxidizing and reducing agents:
(a) $\mathrm{O}_{2}(g)+\mathrm{NO}(g) \longrightarrow \mathrm{NO}_{3}{ }^{-}(a q)$ [acidic]
(b) $\mathrm{CrO}_{4}{ }^{2-}(a q)+\mathrm{Cu}(s) \longrightarrow$

$$
\mathrm{Cr}(\mathrm{OH})_{3}(s)+\mathrm{Cu}(\mathrm{OH})_{2}(s)[\text { basic }]
$$

(c) $\mathrm{AsO}_{4}{ }^{3-}(a q)+\mathrm{NO}_{2}{ }^{-}(a q) \longrightarrow \mathrm{AsO}_{2}{ }^{-}(a q)+\mathrm{NO}_{3}{ }^{-}(a q)$ basic]
21.14 Balance the following skeleton reactions and identify the oxidizing and reducing agents:
(a) $\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+\mathrm{Zn}(s) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{Cr}^{3+}(a q)$ [acidic]
(b) $\mathrm{Fe}(\mathrm{OH})_{2}(s)+\mathrm{MnO}_{4}^{-}(a q) \longrightarrow$

$$
\mathrm{MnO}_{2}(s)+\mathrm{Fe}(\mathrm{OH})_{3}(s)[\text { basic }]
$$

(c) $\mathrm{Zn}(s)+\mathrm{NO}_{3}{ }^{-}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{N}_{2}(g)$ [acidic]
21.15 Balance the following skeleton reactions and identify the oxidizing and reducing agents:

$$
\mathrm{H}_{2} \mathrm{BO}_{3}^{-}(a q)+\mathrm{Cl}^{-}(a q)[\text { basic }]
$$

(b) $\mathrm{CrO}_{4}{ }^{2-}(a q)+\mathrm{N}_{2} \mathrm{O}(g) \longrightarrow \mathrm{Cr}^{3+}(a q)+\mathrm{NO}(g)$ [acidic]
(c) $\mathrm{Br}_{2}(l) \longrightarrow \mathrm{BrO}_{3}^{-}(a q)+\mathrm{Br}^{-}(a q)$ [basic]
21.16 Balance the following skeleton reactions and identify the oxidizing and reducing agents:
(a) $\mathrm{Sb}(s)+\mathrm{NO}_{3}{ }^{-}(a q) \longrightarrow \mathrm{Sb}_{4} \mathrm{O}_{6}(s)+\mathrm{NO}(g)$ [acidic]
(b) $\mathrm{Mn}^{2+}(a q)+\mathrm{BiO}_{3}^{-}(a q) \longrightarrow$

$$
\mathrm{MnO}_{4}^{-}(a q)+\mathrm{Bi}^{3+}(a q)[\text { acidic }]
$$

(c) $\mathrm{Fe}(\mathrm{OH})_{2}(s)+\mathrm{Pb}(\mathrm{OH})_{3}{ }^{-}(a q) \longrightarrow$
$\mathrm{Fe}(\mathrm{OH})_{3}(s)+\mathrm{Pb}(s)$ [basic]
21.17 Balance the following skeleton reactions and identify the oxidizing and reducing agents:
(a) $\mathrm{NO}_{2}(g) \longrightarrow \mathrm{NO}_{3}^{-}(a q)+\mathrm{NO}_{2}^{-}(a q)$ [basic]
(b) $\mathrm{Zn}(s)+\mathrm{NO}_{3}{ }^{-}(a q) \longrightarrow \mathrm{Zn}(\mathrm{OH})_{4}{ }^{2-}(a q)+\mathrm{NH}_{3}(g)$ basic]
(c) $\mathrm{H}_{2} \mathrm{~S}(g)+\mathrm{NO}_{3}^{-}(a q) \longrightarrow \mathrm{S}_{8}(s)+\mathrm{NO}(g)$ [acidic]
21.18 Balance the following skeleton reactions and identify the oxidizing and reducing agents:
(a) $\mathrm{As}_{4} \mathrm{O}_{6}(s)+\mathrm{MnO}_{4}^{-}(a q) \longrightarrow$

$$
\mathrm{AsO}_{4}{ }^{3-}(a q)+\mathrm{Mn}^{2+}(a q)[\text { acidic }]
$$

(b) $\mathrm{P}_{4}(s) \longrightarrow \mathrm{HPO}_{3}{ }^{2-}(a q)+\mathrm{PH}_{3}(g)$ [acidic]
(c) $\mathrm{MnO}_{4}^{-}(a q)+\mathrm{CN}^{-}(a q) \longrightarrow$
$\mathrm{MnO}_{2}(s)+\mathrm{CNO}^{-}(a q)$ [basic]
21.19 Balance the following skeleton reactions and identify the oxidizing and reducing agents:
(a) $\mathrm{SO}_{3}{ }^{2-}(a q)+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{SO}_{4}{ }^{2-}(a q)+\mathrm{Cl}^{-}(a q)$ [basic]
(b) $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{3-}(a q)+\operatorname{Re}(s) \longrightarrow$
$\mathrm{Fe}(\mathrm{CN})_{6}{ }^{4-}(a q)+\mathrm{ReO}_{4}{ }^{-}(a q)[$ basic]
(c) $\mathrm{MnO}_{4}{ }^{-}(a q)+\mathrm{HCOOH}(a q) \longrightarrow$

$$
\left.\mathrm{Mn}^{2+}(a q)+\mathrm{CO}_{2}(g) \text { acidic }\right]
$$

## Problems in Context

21.20 In many residential water systems, the aqueous $\mathrm{Fe}^{3+}$ concentration is high enough to stain sinks and turn drinking water light brown. The iron content is analyzed by first reducing the $\mathrm{Fe}^{3+}$ to $\mathrm{Fe}^{2+}$ and then titrating with $\mathrm{MnO}_{4}{ }^{-}$in acidic solution. Balance the skeleton reaction of the titration step:

$$
\mathrm{Fe}^{2+}(a q)+\mathrm{MnO}_{4}^{-}(a q) \longrightarrow \mathrm{Mn}^{2+}(a q)+\mathrm{Fe}^{3+}(a q)
$$

21.21 Aqua regia, a mixture of concentrated $\mathrm{HNO}_{3}$ and HCl , was developed by alchemists as a means to "dissolve" gold. The process is a redox reaction with the simplified skeleton reaction:

$$
\mathrm{Au}(s)+\mathrm{NO}_{3}^{-}(a q)+\mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{AuCl}_{4}^{-}(a q)+\mathrm{NO}_{2}(g)
$$

(a) Balance the reaction by the half-reaction method.
(b) What are the oxidizing and reducing agents?
(c) What is the function of HCl in aqua regia?

## Voltaic Cells: Using Spontaneous Reactions to Generate Electrical Energy

(Sample Problem 21.2)

## Concept Review Questions

21.22 Consider the following general voltaic cell:

Identify the (a) anode, (b) cathode, (c) salt bridge, (d) electrode at which $\mathrm{e}^{-}$leave the cell, (e) electrode with a positive charge, and (f) electrode that gains mass as the cell operates (assuming that a metal plates out).
21.23 Why does a voltaic cell not operate unless the two compartments are connected through an external circuit?
21.24 What purpose does the salt bridge serve in a voltaic cell, and how does it accomplish this purpose?
21.25 What is the difference between an active and an inactive electrode? Why are inactive electrodes used? Name two substances commonly used for inactive electrodes.
21.26 When a piece of metal A is placed in a solution containing ions of metal B, metal B plates out on the piece of A.
(a) Which metal is being oxidized?
(b) Which metal is being displaced?
(c) Which metal would you use as the anode in a voltaic cell incorporating these two metals?
(d) If bubbles of $\mathrm{H}_{2}$ form when B is placed in acid, will they form if A is placed in acid? Explain.
Skill-Building Exercises (grouped in similar pairs)
21.27 A voltaic cell is constructed with an $\mathrm{Sn} / \mathrm{Sn}^{2+}$ half-cell and a $\mathrm{Zn} / \mathrm{Zn}^{2+}$ half-cell. The zinc electrode is negative.
(a) Write balanced half-reactions and the overall reaction.
(b) Diagram the cell, labeling electrodes with their charges and showing the directions of electron flow in the circuit and of cation and anion flow in the salt bridge.
21.28 A voltaic cell is constructed with an $\mathrm{Ag} / \mathrm{Ag}^{+}$half-cell and a $\mathrm{Pb} / \mathrm{Pb}^{2+}$ half-cell. The silver electrode is positive.
(a) Write balanced half-reactions and the overall reaction.
(b) Diagram the cell, labeling electrodes with their charges and showing the directions of electron flow in the circuit and of cation and anion flow in the salt bridge.
21.29 Consider the following voltaic cell:

(a) In which direction do electrons flow in the external circuit?
(b) In which half-cell does oxidation occur?
(c) In which half-cell do electrons enter the cell?
(d) At which electrode are electrons consumed?
(e) Which electrode is negatively charged?
(f) Which electrode decreases in mass during cell operation?
(g) Suggest a solution for the cathode electrolyte.
(h) Suggest a pair of ions for the salt bridge.
(i) For which electrode could you use an inactive material?
(j) In which direction do anions within the salt bridge move to maintain charge neutrality?
Fr white balanced half-reactions and an overall cell reaction.
21.30 Consider the following voltaic cell:

(a) In which direction do electrons flow in the external circuit?
(b) In which half-cell does reduction occur?
(c) In which half-cell do electrons leave the cell?
(d) At which electrode are electrons generated?
(e) Which electrode is positively charged?
(f) Which electrode increases in mass during cell operation?
(g) Suggest a solution for the anode electrolyte.
(h) Suggest a pair of ions for the salt bridge.
(i) For which electrode could you use an inactive material?
(j) In which direction do cations within the salt bridge move to maintain charge neutrality?
(k) Write balanced half-reactions and an overall cell reaction.
21.31 A voltaic cell is constructed with an $\mathrm{Fe} / \mathrm{Fe}^{2+}$ half-cell and an $\mathrm{Mn} / \mathrm{Mn}^{2+}$ half-cell. The iron electrode is positive.
(a) Write balanced half-reactions and the overall reaction.
(b) Diagram the cell, labeling electrodes with their charges and showing the directions of electron flow in the circuit and of cation and anion flow in the salt bridge.
21.32 A voltaic cell is constructed with a $\mathrm{Cu} / \mathrm{Cu}^{2+}$ half-cell and an $\mathrm{Ni} / \mathrm{Ni}^{2+}$ half-cell. The nickel electrode is negative.
(a) Write balanced half-reactions and the overall reaction.
(b) Diagram the cell, labeling electrodes with their charges and showing the directions of electron flow in the circuit and of cation and anion flow in the salt bridge.
21.33 Write the cell notation for the voltaic cell that incorporates each of the following redox reactions:
(a) $\mathrm{Al}(s)+\mathrm{Cr}^{3+}(a q) \longrightarrow \mathrm{Al}^{3+}(a q)+\mathrm{Cr}(s)$
(b) $\mathrm{Cu}^{2+}(a q)+\mathrm{SO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$

$$
\mathrm{Cu}(s)+\mathrm{SO}_{4}{ }^{2-}(a q)+4 \mathrm{H}^{+}(a q)
$$

21.34 Write a balanced equation from each cell notation:
(a) $\mathrm{Mn}(s)\left|\mathrm{Mn}^{2+}(a q) \| \mathrm{Cd}^{2+}(a q)\right| \mathrm{Cd}(s)$
(b) $\mathrm{Fe}(s)\left|\mathrm{Fe}^{2+}(a q) \| \mathrm{NO}_{3}^{-}(a q)\right| \mathrm{NO}(g) \mid \operatorname{Pt}(s)$

## Cell Potential: Output of a Voltaic Cell

(Sample Problems 21.3 and 21.4)

## - Concept Review Questions

21.35 How is a standard reference electrode used to determine unknown $E_{\text {half-cell }}^{\circ}$ values?
21.36 What does a negative $E_{\text {cell }}^{\circ}$ indicate about a redox reaction? What does it indicate about the reverse reaction?
21.37 The standard cell potential is a thermodynamic state function. How are $E^{\circ}$ values treated similarly to $\Delta H^{\circ}, \Delta G^{\circ}$, and $S^{\circ}$ values? How are they treated differently?

## Skill-Building Exercises (grouped in similar pairs)

21.38 In basic solution, $\mathrm{Se}^{2-}$ and $\mathrm{SO}_{3}{ }^{2-}$ ions react spontaneously:

(a) Write balanced half-reactions for the process.
(b) If $E_{\text {sulfite }}^{\circ}$ is -0.57 V , calculate $E_{\text {selenium }}^{\circ}$.
21.39 In acidic solution, $\mathrm{O}_{3}$ and $\mathrm{Mn}^{2+}$ ion react spontaneously:
$\mathrm{O}_{3}(g)+\mathrm{Mn}^{2+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$

$$
\mathrm{O}_{2}(g)+\mathrm{MnO}_{2}(s)+2 \mathrm{H}^{+}(a q) \quad E_{\mathrm{cell}}^{\circ}=0.84 \mathrm{~V}
$$

(a) Write the balanced half-reactions.
(b) Using Appendix D to find $E_{\text {ozone }}^{\circ}$, calculate $E_{\text {manganese }}^{\circ}$
21.40 Use the emf series (Appendix D) to arrange the species.
(a) In order of decreasing strength as oxidizing agents: $\mathrm{Fe}^{3+}$, $\mathrm{Br}_{2}, \mathrm{Cu}^{2+}$
(b) In order of increasing strength as oxidizing agents: $\mathrm{Ca}^{2+}$, $\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}, \mathrm{Ag}^{+}$
21.41 Use the emf series (Appendix D) to arrange the species.
(a) In order of decreasing strength as reducing agents: $\mathrm{SO}_{2}$, $\mathrm{PbSO}_{4}, \mathrm{MnO}_{2}$
(b) In order of increasing strength as reducing agents: $\mathrm{Hg}, \mathrm{Fe}, \mathrm{Sn}$
21.42 Balance each skeleton reaction, calculate $E_{\text {cell }}^{\circ}$, and state whether the reaction is spontaneous:
(a) $\mathrm{Co}(s)+\mathrm{H}^{+}(a q) \longrightarrow \mathrm{Co}^{2+}(a q)+\mathrm{H}_{2}(g)$
(b) $\mathrm{Mn}^{2+}(a q)+\mathrm{Br}_{2}(l) \longrightarrow \mathrm{MnO}_{4}^{-}(a q)+\mathrm{Br}^{-}(a q)$ [acidic]
(c) $\mathrm{Hg}_{2}{ }^{2+}(a q) \longrightarrow \mathrm{Hg}^{2+}(a q)+\mathrm{Hg}(l)$
21.43 Balance each skeleton reaction, calculate $E_{\text {cell }}^{\circ}$, and state whether the reaction is spontaneous:
(a) $\mathrm{Cl}_{2}(g)+\mathrm{Fe}^{2+}(a q) \longrightarrow \mathrm{Cl}^{-}(a q)+\mathrm{Fe}^{3+}(a q)$
(b) $\mathrm{Mn}^{2+}(a q)+\mathrm{Co}^{3+}(a q) \longrightarrow \mathrm{MnO}_{2}(s)+\mathrm{Co}^{2+}(a q)$ [acidic]
(c) $\mathrm{AgCl}(s)+\mathrm{NO}(g) \longrightarrow$

$$
\mathrm{Ag}(s)+\mathrm{Cl}^{-}(a q)+\mathrm{NO}_{3}^{-}(a q)[\text { acidic }]
$$

21.44 Balance each skeleton reaction, calculate $E_{\text {cell }}^{\circ}$, and state whether the reaction is spontaneous:
(a) $\mathrm{Ag}(s)+\mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{Ag}^{+}(a q)+\mathrm{Cu}(s)$
(b) $\mathrm{Cd}(s)+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q) \longrightarrow \mathrm{Cd}^{2+}(a q)+\mathrm{Cr}^{3+}(a q)$
(c) $\mathrm{Ni}^{2+}(a q)+\mathrm{Pb}(s) \longrightarrow \mathrm{Ni}(s)+\mathrm{Pb}^{2+}(a q)$
21.45 Balance each skeleton reaction, calculate $E_{\text {cell }}^{\circ}$, and state whether the reaction is spontaneous:
(a) $\mathrm{Cu}^{+}(a q)+\mathrm{PbO}_{2}(s)+\mathrm{SO}_{4}{ }^{2-}(a q) \longrightarrow$

$$
\mathrm{PbSO}_{4}(s)+\mathrm{Cu}^{2+}(a q)[\text { acidic }]
$$

(b) $\mathrm{H}_{2} \mathrm{O}_{2}(a q)+\mathrm{Ni}^{2+}(a q) \longrightarrow \mathrm{O}_{2}(g)+\mathrm{Ni}(s)$ [acidic]
(c) $\mathrm{MnO}_{2}(s)+\mathrm{Ag}^{+}(a q) \longrightarrow \mathrm{MnO}_{4}^{-}(a q)+\mathrm{Ag}(s)[$ basic]
21.46 Use the following half-reactions to write three spontaneous reactions, calculate $E_{\text {cell }}^{\circ}$ for each reaction, and rank the strengths of the oxidizing and reducing agents:
(1) $\mathrm{Al}^{3+}{ }_{(a q)}+3 \mathrm{e}^{-} \longrightarrow \mathrm{Al}(s) \quad E^{\circ}=-1.66 \mathrm{~V}$
(2) $\mathrm{N}_{2} \mathrm{O}_{4}(g)+2 \mathrm{e}^{-} \longrightarrow 2 \mathrm{NO}_{2}^{-}(a q) \quad E^{\circ}=0.867 \mathrm{~V}$
(3) $\mathrm{SO}_{4}{ }^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-} \longrightarrow \mathrm{SO}_{3}{ }^{2-}(a q)+2 \mathrm{OH}^{-}(a q)$

$$
E^{\circ}=0.93 \mathrm{~V}
$$

21.47 Use the following half-reactions to write three spontaneous reactions, calculate $E_{\text {cell }}^{\circ}$ for each reaction, and rank the strengths of the oxidizing and reducing agents:
(1) $\mathrm{Au}^{+}(a q)+\mathrm{e}^{-} \longrightarrow \mathrm{Au}(s) \quad E^{\circ}=1.69 \mathrm{~V}$
(2) $\mathrm{N}_{2} \mathrm{O}(g)+2 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{N}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l)$ $E^{\circ}=1.77 \mathrm{~V}$
(3) $\mathrm{Cr}^{3+}(a q)+3 \mathrm{e}^{-} \longrightarrow \mathrm{Cr}(s) \quad E^{\circ}=-0.74 \mathrm{~V}$
21.48 Use the following half-reactions to write three spontaneous redetions, alatate Erif for each reaction, and rank the strengths of the oxidizing and reducing agents:
(1) $2 \mathrm{HClO}(a q)+2 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cl}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)$ $E^{\circ}=1.63 \mathrm{~V}$
(2) $\mathrm{Pt}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Pt}(s) \quad E^{\circ}=1.20 \mathrm{~V}$
(3) $\mathrm{PbSO}_{4}(s)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Pb}(s)+\mathrm{SO}_{4}{ }^{2-}(a q) \quad E^{\circ}=-0.31 \mathrm{~V}$
21.49 Use the following half-reactions to write three spontaneous reactions, calculate $E_{\text {cell }}^{\circ}$ for each reaction, and rank the strengths of the oxidizing and reducing agents:
(1) $\mathrm{I}_{2}(s)+2 \mathrm{e}^{-} \longrightarrow 2 \mathrm{I}^{-}(a q) \quad E^{\circ}=0.53 \mathrm{~V}$
(2) $\mathrm{S}_{2} \mathrm{O}_{8}{ }^{2-}(a q)+2 \mathrm{e}^{-} \longrightarrow 2 \mathrm{SO}_{4}{ }^{2-}(a q) \quad E^{\circ}=2.01 \mathrm{~V}$
(3) $\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+14 \mathrm{H}^{+}(a q)+6 \mathrm{e}^{-} \longrightarrow$

$$
2 \mathrm{Cr}^{3+}(a q)+7 \mathrm{H}_{2} \mathrm{O}(l) \quad E^{\circ}=1.33 \mathrm{~V}
$$

## Problems in Context

21.50 When metal A is placed in a solution of a salt of metal B, the surface of metal A changes color. When metal B is placed in acid solution, gas bubbles form on the surface of the metal. When metal A is placed in a solution of a salt of metal C , no change is observed in the solution or on the metal A surface. Will metal C cause formation of $\mathrm{H}_{2}$ when placed in acid solution? Rank metals $\mathrm{A}, \mathrm{B}$, and C in order of decreasing reducing strength.
21.51 When a clean iron nail is placed in an aqueous solution of copper(II) sulfate, the nail becomes coated with a brownish black material.
(a) What is the material coating the iron?
(b) What are the oxidizing and reducing agents?
(c) Can this reaction be made into a voltaic cell?
(d) Write the balanced equation for the reaction.
(e) Calculate $E_{\text {cell }}^{\circ}$ for the process.

## Free Energy and Electrical Work

(Sample Problems 21.5 to 21.7)

## - Concept Review Questions

21.52 (a) How do the relative magnitudes of $Q$ and $K$ relate to the signs of $\Delta G$ and $E_{\text {cell }}$ ? Explain.
(b) Can a cell do work when $Q / K>1$ or $Q / K<1$ ? Explain.
21.53 A voltaic cell consists of a metal $\mathrm{A} / \mathrm{A}^{+}$electrode and a metal $\mathrm{B} / \mathrm{B}^{+}$electrode, with the $\mathrm{A} / \mathrm{A}^{+}$electrode negative. The initial $\left[\mathrm{A}^{+}\right] /\left[\mathrm{B}^{+}\right]$is such that $E_{\text {cell }}>E_{\text {cell }}^{\circ}$.
(a) How do $\left[\mathrm{A}^{+}\right]$and $\left[\mathrm{B}^{+}\right]$change as the cell operates?
(b) How does $E_{\text {cell }}$ change as the cell operates?
(c) What is $\left[\mathrm{A}^{+}\right] /\left[\mathrm{B}^{+}\right]$when $E_{\text {cell }}=E_{\text {cell }}^{\circ}$ ? Explain.
(d) Is it possible for $E_{\text {cell }}$ to be less than $E_{\text {cell }}^{\circ}$ ? Explain.
21.54 Explain whether $E_{\text {cell }}$ of a voltaic cell will increase or decrease with each of the following changes:
(a) Decrease in cell temperature
(b) Increase in [active ion] in the anode compartment
(c) Increase in [active ion] in the cathode compartment
(d) Increase in pressure of a gaseous reactant in the cathode compartment
21.55 In a concentration cell, is the more concentrated electrolyte in the cathode or the anode compartment? Explain.
Skill-Building Exercises (grouped in similar pairs)
21.56 What is the value of the equilibrium constant for the reaction between each pair at $25^{\circ} \mathrm{C}$ ?
(a) $\mathrm{Ni}(s)$ and $\mathrm{Ag}^{+}(a q)$
(b) $\mathrm{Fe}(s)$ and $\mathrm{Cr}^{3+}(a q)$
21.57 What is the value of the equilibrium constant for the reaction between each pair at $25^{\circ} \mathrm{C}$ ?
(a) $\mathrm{Al}(s)$ and $\mathrm{Cd}^{2+}(a q)$
(b) $\mathrm{I}_{2}(s)$ and $\mathrm{Br}^{-}(\mathrm{aq}) \quad \mathrm{PDF}$
21.58 What is the value of the equilibrium constant for the reaction between each pair at $25^{\circ} \mathrm{C}$ ?
(a) $\mathrm{Ag}(s)$ and $\mathrm{Mn}^{2+}(a q)$
(b) $\mathrm{Cl}_{2}(g)$ and $\mathrm{Br}^{-}(a q)$
21.59 What is the value of the equilibrium constant for the reaction between each pair at $25^{\circ} \mathrm{C}$ ?
(a) $\mathrm{Cr}(s)$ and $\mathrm{Cu}^{2+}(a q)$
(b) $\mathrm{Sn}(s)$ and $\mathrm{Pb}^{2+}(a q)$
21.60 Calculate $\Delta G^{\circ}$ for each of the reactions in Problem 21.56.
21.61 Calculate $\Delta G^{\circ}$ for each of the reactions in Problem 21.57.
21.62 Calculate $\Delta G^{\circ}$ for each of the reactions in Problem 21.58.
21.63 Calculate $\Delta G^{\circ}$ for each of the reactions in Problem 21.59.
21.64 What are $E_{\text {cell }}^{\circ}$ and $\Delta G^{\circ}$ of a redox reaction at $25^{\circ} \mathrm{C}$ for which $n=1$ and $K=5.0 \times 10^{4}$ ?
21.65 What are $E_{\text {cell }}^{\circ}$ and $\Delta G^{\circ}$ of a redox reaction at $25^{\circ} \mathrm{C}$ for which $n=1$ and $K=5.0 \times 10^{-6}$ ?
21.66 What are $E_{\text {cell }}^{\circ}$ and $\Delta G^{\circ}$ of a redox reaction at $25^{\circ} \mathrm{C}$ for which $n=2$ and $K=65$ ?
21.67 What are $E_{\text {cell }}^{\circ}$ and $\Delta G^{\circ}$ of a redox reaction at $25^{\circ} \mathrm{C}$ for which $n=2$ and $K=0.065$ ?
21.68 A voltaic cell consists of a standard hydrogen electrode in one half-cell and a $\mathrm{Cu} / \mathrm{Cu}^{2+}$ half-cell. Calculate $\left[\mathrm{Cu}^{2+}\right]$ when $E_{\text {cell }}$ is 0.22 V .
21.69 A voltaic cell consists of an $\mathrm{Mn} / \mathrm{Mn}^{2+}$ half-cell and a $\mathrm{Pb} / \mathrm{Pb}^{2+}$ half-cell. Calculate $\left[\mathrm{Pb}^{2+}\right]$ when $\left[\mathrm{Mn}^{2+}\right]$ is 1.4 M and $E_{\text {cell }}$ is 0.44 V .
21.70 A voltaic cell with $\mathrm{Ni} / \mathrm{Ni}^{2+}$ and $\mathrm{Co} / \mathrm{Co}^{2+}$ half-cells has the following initial concentrations: $\left[\mathrm{Ni}^{2+}\right]=0.80 \mathrm{M} ;\left[\mathrm{Co}^{2+}\right]=$ 0.20 M .
(a) What is the initial $E_{\text {cell }}$ ?
(b) What is $\left[\mathrm{Ni}^{2+}\right]$ when $E_{\text {cell }}$ reaches 0.03 V ?
(c) What are the equilibrium concentrations of the ions?
21.71 A voltaic cell with $\mathrm{Mn} / \mathrm{Mn}^{2+}$ and $\mathrm{Cd} / \mathrm{Cd}^{2+}$ half-cells has the following initial concentrations: $\left[\mathrm{Mn}^{2+}\right]=0.090 \mathrm{M} ;\left[\mathrm{Cd}^{2+}\right]=$ 0.060 M .
(a) What is the initial $E_{\text {cell }}$ ?
(b) What is $E_{\text {cell }}$ when $\left[\mathrm{Cd}^{2+}\right]$ reaches 0.050 M ?
(c) What is $\left[\mathrm{Mn}^{2+}\right]$ when $E_{\text {cell }}$ reaches 0.055 V ?
(d) What are the equilibrium concentrations of the ions?
21.72 A concentration cell consists of two $\mathrm{H}_{2} / \mathrm{H}^{+}$half-cells. Halfcell A has $\mathrm{H}_{2}$ at 0.95 atm bubbling into 0.10 M HCl . Half-cell B has $\mathrm{H}_{2}$ at 0.60 atm bubbling into 2.0 M HCl . Which half-cell houses the anode? What is the voltage of the cell?
21.73 A concentration cell consists of two $\mathrm{Sn} / \mathrm{Sn}^{2+}$ half-cells. The electrolyte in compartment A is $0.13 \mathrm{M} \mathrm{Sn}\left(\mathrm{NO}_{3}\right)_{2}$. The electrolyte in B is $0.87 \mathrm{M} \mathrm{Sn}\left(\mathrm{NO}_{3}\right)_{2}$. Which half-cell houses the cathode? What is the voltage of the cell?

## Electrochemical Processes in Batteries

## - Concept Review Questions

21.74 What is the direction of electron flow with respect to the anode and the cathode in a battery? Explain.
21.75 In the everyday batteries used for flashlights, toys, etc., no salt bridge is evident. What is used in these cells to separate the anode and cathode compartments?
21.76 Both a D-sized and an AAA-sized alkaline battery have an output of 1.5 V . What property of the cell potential allows this to occur? What is different about these two batteries?

## EAProbtems in Context

21.77 Many common electrical devices require the use of more than one battery.
(a) How many alkaline batteries must be placed in series to light a flashlight with a $6.0-\mathrm{V}$ bulb?
(b) What is the voltage requirement of a camera that uses six silver batteries?
(c) How many volts can a car battery deliver if two of its anode/cathode cells are shorted?

## Corrosion: A Case of Environmental Electrochemistry <br> - Concept Review Questions

21.78 During reconstruction of the Statue of Liberty, Teflon spacers were placed between the iron skeleton and the copper plates that cover the statue. What purpose do these spacers serve?
21.79 Why do steel bridge-supports rust at the waterline but not above or below it?
21.80 After the 1930s, chromium replaced nickel for corrosion resistance and appearance on car bumpers and trim. How does chromium protect steel from corrosion?
21.81 Which of the following metals are suitable for use as sacrificial anodes to protect against corrosion of underground iron pipes? If any are not suitable, explain why:
(a) Aluminum
(b) Magnesium
(c) Sodium
(d) Lead
(e) Nickel
(f) Zinc
(g) Chromium

## Electrolytic Cells: Using Electrical Energy to Drive Nonspontaneous Reactions <br> (Sample Problems 21.8 to 21.10)

## - Concept Review Questions

Note: Unless stated otherwise, assume that the electrolytic cells in the following problems operate at 100\% efficiency.
21.82 Consider the following general electrolytic cell:

(a) At which electrode does oxidation occur?
(b) At which electrode does elemental M form?
(c) At which electrode are electrons being released by ions?
(d) At which electrode are electrons entering the cell?
21.83 A voltaic cell consists of $\mathrm{Cr} / \mathrm{Cr}^{3+}$ and $\mathrm{Cd} / \mathrm{Cd}^{2+}$ half-cells with all components in their standard states. After 10 minutes of operation, a thin coating of cadmium metal has plated out on the cathode. Describe what will happen if you attach the negative terminal of a dry cell $(1.5 \mathrm{~V})$ to the cell cathode and the positive terminal to the cell anode.
21.84 Why are $E_{\text {half-cell }}$ values for the oxidation and reduction of water different from $E_{\text {half-cell }}^{\circ}$ values for the sane processes?
21.85 In an aqueous electrolytic cell, nitrate ions never react at the anode, but nitrite ions do. Explain.
21.86 How does overvoltage influence the products in the electrolysis of aqueous salts?

## - Skill-Building Exercises (grouped in similar pairs)

21.87 In the electrolysis of molten NaBr ,
(a) What product forms at the anode?
(b) What product forms at the cathode?
21.88 In the electrolysis of molten $\mathrm{BaI}_{2}$,
(a) What product forms at the negative electrode?
(b) What product forms at the positive electrode?
21.89 In the electrolysis of a molten mixture of KI and $\mathrm{MgF}_{2}$, identify the product that forms at the anode and at the cathode.
21.90 In the electrolysis of a molten mixture of CsBr and $\mathrm{SrCl}_{2}$, identify the product that forms at the negative electrode and at the positive electrode.
21.91 In the electrolysis of a molten mixture of NaCl and $\mathrm{CaBr}_{2}$, identify the product that forms at the anode and at the cathode.
21.92 In the electrolysis of a molten mixture of RbF and $\mathrm{CaCl}_{2}$, identify the product that forms at the negative electrode and at the positive electrode.
21.93 Identify those elements that can be prepared by electrolysis of their aqueous salts: copper, barium, aluminum, bromine.
21.94 Identify those elements that can be prepared by electrolysis of their aqueous salts: strontium, gold, tin, chlorine.
21.95 Identify those elements that can be prepared by electrolysis of their aqueous salts: lithium, iodine, zinc, silver.
21.96 Identify those elements that can be prepared by electrolysis of their aqueous salts: fluorine, manganese, iron, cadmium.
21.97 What product forms at each electrode in the aqueous electrolysis of the following salts: (a) LiF ; (b) $\mathrm{SnSO}_{4}$ ?
21.98 What product forms at each electrode in the aqueous electrolysis of the following salts: (a) $\mathrm{ZnBr}_{2}$; (b) $\mathrm{Cu}\left(\mathrm{HCO}_{3}\right)_{2}$ ?
21.99 What product forms at each electrode in the aqueous electrolysis of the following salts: (a) $\mathrm{Cr}\left(\mathrm{NO}_{3}\right)_{3}$; (b) $\mathrm{MnCl}_{2}$ ?
21.100 What product forms at each electrode in the aqueous electrolysis of the following salts: (a) $\mathrm{FeI}_{2}$; (b) $\mathrm{K}_{3} \mathrm{PO}_{4}$ ?
21.101 Electrolysis of molten $\mathrm{MgCl}_{2}$ is the final production step in the isolation of magnesium from seawater by the Dow process (Section 22.4). Assuming that 45.6 g of Mg metal forms,
(a) How many moles of electrons are required?
(b) How many coulombs are required?
(c) How many amps will produce this amount in 3.50 h ?
21.102 Electrolysis of molten NaCl in a Downs cell is the major isolation step in the production of sodium metal (Section 22.4). Assuming that 215 g of Na metal forms,
(a) How many moles of electrons are required?
(b) How many coulombs are required?
(c) How many amps will produce this amount in 9.50 h ?
21.103 How many grams of radium can form by passing 235 C through an electrolytic cell containing a molten radium salt?
21.104 How many grams of aluminum can form by passing 305 C through an electrolytic cell containing a molten aluminum salt?
21.105 How many seconds does it take to deposit 65.5 g of Zn on a steengateanhere ef is passed through a $\mathrm{ZnSO}_{4}$ solution?
21.106 How many seconds does it take to deposit 1.63 g of Ni on a decorative drawer handle when 13.7 A is passed through a $\mathrm{Ni}\left(\mathrm{NO}_{3}\right)_{2}$ solution?

## Problems in Context

21.107 A professor adds $\mathrm{Na}_{2} \mathrm{SO}_{4}$ to water to facilitate its electrolysis in a lecture demonstration. (a) What is the purpose of the $\mathrm{Na}_{2} \mathrm{SO}_{4}$ ? (b) Why is the water electrolyzed instead of the salt?
21.108 Subterranean brines in parts of the United States are rich in iodides and bromides and serve as an industrial source of these elements. In one recovery method, the brines are evaporated to dryness and then melted and electrolyzed. Which halogen is more likely to form from this treatment? Why?
21.109 Zinc plating (galvanizing) is an important means of corrosion protection. Although the process is done customarily by dipping the object into molten zinc, the metal can also be electroplated from aqueous solutions. How many grams of zinc can be deposited on a steel tank from a $\mathrm{ZnSO}_{4}$ solution when a $0.855-\mathrm{A}$ current flows for 2.50 days?

## Comprehensive Problems

21.110 The $\mathrm{MnO}_{2}$ used in alkaline batteries can be produced by an electrochemical process of which one half-reaction is

$$
\mathrm{Mn}^{2+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{MnO}_{2}(s)+4 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-}
$$

If a current of 25.0 A is used, how many hours are needed to produce 1.00 kg of $\mathrm{MnO}_{2}$ ? At which electrode is the $\mathrm{MnO}_{2}$ formed?
21.111 Car manufacturers are developing engines that use $\mathrm{H}_{2}$ as fuel. In Iceland, Sweden, and other parts of Scandinavia, where hydroelectric plants produce inexpensive electric power, the $\mathrm{H}_{2}$ can be made industrially by the electrolysis of water.
(a) How many coulombs are needed to produce $3.5 \times 10^{6} \mathrm{~L}$ of $\mathrm{H}_{2}$ gas at 12.0 atm and $25^{\circ} \mathrm{C}$ ? (Assume the ideal gas law applies.)
(b) If the coulombs are supplied at 1.44 V , how many joules are produced?
(c) If the combustion of oil yields $4.0 \times 10^{4} \mathrm{~kJ} / \mathrm{kg}$, what mass of oil must be burned to yield the number of joules in part (b)?
21.112 The overall cell reaction occurring in an alkaline battery is $\mathrm{Zn}(s)+\mathrm{MnO}_{2}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{ZnO}(s)+\mathrm{Mn}(\mathrm{OH})_{2}(s)$
(a) How many moles of electrons flow per mole of reaction?
(b) If 4.50 g of zinc is oxidized, how many grams of manganese dioxide and of water are consumed?
(c) What is the total mass of reactants consumed in part (b)?
(d) How many coulombs are produced in part (b)?
(e) In practice, voltaic cells of a given capacity (coulombs) are heavier than the calculation in part (c) indicates. Explain.
21.113 An inexpensive and accurate method of measuring the quantity of electricity passing through a circuit is to pass it through a solution of a metal ion and weigh the metal deposited. A silver electrode immersed in an $\mathrm{Ag}^{+}$solution weighs 1.7854 g before the current passes and weighs 1.8016 g after the current has passed. How many coulombs have passed?
21.114 Brass, an alloy of copper and zinc, can be produced by simultaneously electroplating the two metals from a solution containing their $2+$ ions. If $65.0 \%$ of the total current is used to plate copper, while $35.0 \%$ goes to plating zinc, what is the mass percent of copper in the brass?
21.115 Compare and contrast a voltaic cell and an electrolytic cell with respect to each of the following:
(a) Sign of the free energy change
(b) Nature of the half-reaction at the anode ago PDF
(c) Nature of the half-reaction at the cathode
(d) Charge on the electrode labeled "anode"
(e) Electrode from which electrons leave the cell
21.116 A thin circular-disk earring 4.00 cm in diameter is plated with a coating of gold 0.25 mm thick from an $\mathrm{Au}^{3+}$ bath.
(a) How many days does it take to deposit the gold on one side of one earring if the current is $0.013 \mathrm{~A}\left(d\right.$ of gold $\left.=19.3 \mathrm{~g} / \mathrm{cm}^{3}\right)$ ?
(b) How many days does it take to deposit the gold on both sides of the pair of earrings?
(c) If the price of gold is $\$ 320$ per troy ounce $(31.10 \mathrm{~g})$, what is the total cost of the gold plating?
21.117 (a) How many minutes does it take to form 10.0 L of $\mathrm{O}_{2}$ measured at 99.8 kPa and $28^{\circ} \mathrm{C}$ from water if a current of 1.3 A passes through the electrolytic cell? (b) What mass of $\mathrm{H}_{2}$ forms?
21.118 Trains powered by electricity, including subways, use direct current. One conductor is the overhead wire (or "third rail" for subways), and the other is the rails upon which the wheels run. The rails are on supports in contact with the ground. To minimize corrosion, should the overhead wire or the rails be connected to the positive terminal? Explain.
21.119 A silver button battery used in a watch contains 0.75 g of zinc and can run until $80 \%$ of the zinc is consumed. (a) How many days can the battery run at a current of 0.85 microamps ( $10^{-6} \mathrm{amps}$ )? (b) When the battery dies, $95 \%$ of the $\mathrm{Ag}_{2} \mathrm{O}$ has been consumed. How many grams of Ag was used to make the battery? (c) If Ag costs $\$ 13.00$ per troy ounce ( 31.10 g ), what is the cost of the Ag consumed each day the watch runs?
21.120 Like any piece of apparatus, an electrolytic cell operates at less than $100 \%$ efficiency. A cell depositing Cu from a $\mathrm{Cu}^{2+}$ bath
operates for 10 h with an average current of 5.8 A . If 53.4 g of copper is deposited, at what efficiency is the cell operating?
21.121 Commercial electrolysis is performed on both molten NaCl and aqueous NaCl solutions. Identify the anode product, cathode product, species reduced, and species oxidized for the (a) molten electrolysis and (b) aqueous electrolysis.
21.122 To examine the effect of ion removal on cell voltage, a chemist constructs two voltaic cells, each with a standard hydrogen electrode in one compartment. One cell also contains a $\mathrm{Pb} / \mathrm{Pb}^{2+}$ half-cell; the other contains a $\mathrm{Cu} / \mathrm{Cu}^{2+}$ half-cell.
(a) What is $E^{\circ}$ of each cell at 298 K ?
(b) Which electrode in each cell is negative?
(c) When $\mathrm{Na}_{2} \mathrm{~S}$ solution is added to the $\mathrm{Pb}^{2+}$ electrolyte, solid PbS forms. What happens to the cell voltage?
(d) When sufficient $\mathrm{Na}_{2} \mathrm{~S}$ is added to the $\mathrm{Cu}^{2+}$ electrolyte, CuS forms and $\left[\mathrm{Cu}^{2+}\right]$ drops to $1 \times 10^{-16} \mathrm{M}$. Find the cell voltage.
21.123 Electrodes used in electrocardiography are disposable, and many incorporate silver. The metal is deposited in a thin layer on a small plastic "button," and then some is converted to AgCl :

$$
\mathrm{Ag}(s)+\mathrm{Cl}^{-}(a q) \rightleftharpoons \mathrm{AgCl}(s)+\mathrm{e}^{-}
$$

(a) If the surface area of the button is $2.0 \mathrm{~cm}^{2}$ and the thickness of the silver layer is $7.5 \times 10^{-6} \mathrm{~m}$, calculate the volume (in $\mathrm{cm}^{3}$ ) of Ag used in one electrode.
(b) The density of silver metal is $10.5 \mathrm{~g} / \mathrm{cm}^{3}$. How many grams of silver are used per electrode?
(c) If Ag is plated on the button from an $\mathrm{Ag}^{+}$solution with a current of 12.0 mA , how many minutes does the plating take?
(d) If bulk silver costs $\$ 13.00$ per troy ounce ( 31.10 g ), what is the cost (in cents) of the silver in one disposable electrode?
E21. 124 conmer aluminum production is done by the electrolysis of a bath containing $\mathrm{Al}_{2} \mathrm{O}_{3}$ dissolved in molten $\mathrm{Na}_{3} \mathrm{AlF}_{6}$. Why isn't it done by electrolysis of an aqueous $\mathrm{AlCl}_{3}$ solution?
21.125 Comparing the standard electrode potentials $\left(E^{\circ}\right)$ of the Group $1 \mathrm{~A}(1)$ metals $\mathrm{Li}, \mathrm{Na}$, and K with the negative of their first ionization energies reveals a discrepancy:
Ionization process reversed: $\mathrm{M}^{+}(g)+\mathrm{e}^{-} \rightleftharpoons \mathrm{M}(g) \quad(-\mathrm{IE})$ Electrode reaction: $\quad \mathrm{M}^{+}(a q)+\mathrm{e}^{-} \rightleftharpoons \mathrm{M}(s) \quad\left(E^{\circ}\right)$

| Metal | $-\mathrm{IE}(\mathrm{kJ} / \mathrm{mol})$ | $E^{\circ}(\mathrm{V})$ |
| :--- | :---: | :---: |
| Li | -520 | -3.05 |
| Na | -496 | -2.71 |
| K | -419 | -2.93 |

Note that the electrode potentials do not decrease smoothly down the group, as the ionization energies do. You might expect that if it is more difficult to remove an electron from an atom to form a gaseous ion (larger IE), then it would be less difficult to add an electron to an aqueous ion to form an atom (smaller $E^{\circ}$ ), yet $\mathrm{Li}^{+}(a q)$ is more difficult to reduce than $\mathrm{Na}^{+}(a q)$. Applying Hess's law, use an approach similar to that for a Born-Haber cycle to break down the process occurring at the electrode into three steps and label the energy involved in each step. How can you account for the discrepancy?
21.126 To improve conductivity in the electroplating of automobile bumpers, a thin coating of copper separates the steel from a heavy coating of chromium.
(a) What mass of Cu is deposited on an automobile trim piece if plating continues for 1.25 h at a current of 5.0 A ?
(b) If the area of the trim piece is $50.0 \mathrm{~cm}^{2}$, what is the thickness of the Cu coating ( $d$ of $\mathrm{Cu}=8.95 \mathrm{~g} / \mathrm{cm}^{3}$ )?
21.127 In Appendix D, standard electrode potentials range from about +3 to -3 V . Thus, it might seem possible to use a half-cell from each end of this range to construct a cell with a voltage of approximately 6 V . However, most commercial aqueous voltaic cells have $E^{\circ}$ values of 1.5 to 2 V . Why are there no aqueous cells with significantly higher potentials?
21.128 Tin is used to coat "tin" cans used for food storage. If the tin is scratched and the iron of the can exposed, will the iron corrode more or less rapidly than if the tin were not present? Inside the can, the tin itself is coated with a clear varnish. Explain.
21.129 Commercial electrolytic cells for producing aluminum operate at 5.0 V and $100,000 \mathrm{~A}$.
(a) How long does it take to produce exactly 1 metric ton ( 1000 kg ) of aluminum?
(b) How much electrical power (in kilowatt-hours, $\mathrm{kW} \cdot \mathrm{h}$ ) is used $\left[1 \mathrm{~W}=1 \mathrm{~J} / \mathrm{s} ; 1 \mathrm{~kW} \cdot \mathrm{~h}=3.6 \times 10^{3} \mathrm{~kJ}\right]$ ?
(c) If electricity costs $0.90 \propto$ per $\mathrm{kW} \cdot \mathrm{h}$ and cell efficiency is $90 . \%$, what is the cost of electricity to produce exactly 1 lb of aluminum?
21.130 Magnesium bars are connected electrically to underground iron pipes to serve as sacrificial anodes.
(a) Do electrons flow from the bar to the pipe or the reverse?
(b) A $12-\mathrm{kg} \mathrm{Mg}$ bar is attached to an iron pipe, and it takes 8.5 yr for the Mg to be consumed. What is the average current flowing between the Mg and the Fe during this period?
21.131 Bubbles of $\mathrm{H}_{2}$ form when metal D is placed in hot $\mathrm{H}_{2} \mathrm{O}$. No reaction occurs when $D$ is placed in a solution of a salt of metal E , but D is discolored and coated immediately phengraced ipaE solution of a salt of metal $F$. What happens if $E$ is placed in a solution of a salt of metal F? Rank metals D, E, and F in order of increasing reducing strength.
21.132 Calcium is obtained industrially by electrolysis of molten $\mathrm{CaCl}_{2}$ and is used in aluminum alloys. How many coulombs are needed to produce 10.0 g of Ca metal? If a cell runs at 15 A , how many minutes will it take to produce 10.0 g of $\mathrm{Ca}(s)$ ?
21.133 In addition to reacting with gold (see Problem 21.21), aqua regia is used to bring other precious metals into solution. Balance the skeleton equation for the reaction with Pt :

$$
\mathrm{Pt}(s)+\mathrm{NO}_{3}^{-}(a q)+\mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{PtCl}_{6}^{2-}(a q)+\mathrm{NO}(g)
$$

21.134 The following reactions are used in batteries:

$$
\begin{array}{lll}
\text { I } & 2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(l) & E_{\text {cell }}=1.23 \mathrm{~V} \\
\text { II } & \mathrm{Pb}(s)+\mathrm{PbO}_{2}(s)+2 \mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow & \\
& 2 \mathrm{PbSO}_{4}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) & E_{\text {cell }}=2.04 \mathrm{~V} \\
\text { III } & 2 \mathrm{Na}(l)+\mathrm{FeCl}_{2}(s) \longrightarrow 2 \mathrm{NaCl}(s)+\mathrm{Fe}(s) & E_{\text {cell }}=2.35 \mathrm{~V}
\end{array}
$$

Reaction I is used in fuel cells, II in the automobile lead-acid battery, and III in an experimental high-temperature battery for powering electric vehicles. The aim is to obtain as much work as possible from a cell, while keeping its weight to a minimum.
(a) In each cell, find the moles of electrons transferred and $\Delta G$.
(b) Calculate the ratio, in $\mathrm{kJ} / \mathrm{g}$, of $w_{\max }$ to mass of reactants for each of the cells. Which has the highest ratio, which the lowest, and why? (Note: For simplicity, ignore the masses of cell components that do not appear in the cell as reactants, including electrode materials, electrolytes, separators, cell casing, wiring, etc.)
21.135 A current is applied to two electrolytic cells in series. In the first, silver is deposited; in the second, a zinc electrode is consumed. How much Ag is plated out if 1.2 g of Zn dissolves?
21.136 You are investigating a particular chemical reaction. State all the types of data available in standard tables that enable you to calculate the equilibrium constant for the reaction at 298 K .
21.137 In an electric power plant, personnel monitor the $\mathrm{O}_{2}$ content of boiler feed water to prevent corrosion of the boiler tubes. Why does Fe corrode faster in steam and hot water than in cold water? 21.138 A voltaic cell using $\mathrm{Cu} / \mathrm{Cu}^{2+}$ and $\mathrm{Sn} / \mathrm{Sn}^{2+}$ half-cells is set up at standard conditions, and each compartment has a volume of 345 mL . The cell delivers 0.17 A for 48.0 h . (a) How many grams of $\mathrm{Cu}(s)$ are deposited? (b) What is the $\left[\mathrm{Cu}^{2+}\right]$ remaining? 21.139 The $E_{\text {half-cell }}$ for the reduction of water is very different from the $E_{\text {half-cell }}^{\circ}$ value. Calculate the $E_{\text {half-cell }}$ value when $\mathrm{H}_{2}$ is in its standard state.
21.140 From the skeleton equations below, create a list of balanced half-reactions in which the strongest oxidizing agent is on top and the weakest is on the bottom:

$$
\begin{aligned}
\mathrm{U}^{3+}(a q)+\mathrm{Cr}^{3+}(a q) & \longrightarrow \mathrm{Cr}^{2+}(a q)+\mathrm{U}^{4+}(a q) \\
\mathrm{Fe}(s)+\mathrm{Sn}^{2+}(a q) & \longrightarrow \mathrm{Sn}(s)+\mathrm{Fe}^{2+}(a q) \\
\mathrm{Fe}(s)+\mathrm{U}^{4+}(a q) & \longrightarrow \text { no reaction } \\
\mathrm{Cr}^{3+}(a q)+\mathrm{Fe}(s) & \longrightarrow \mathrm{Cr}^{2+}(a q)+\mathrm{Fe}^{2+}(a q) \\
\mathrm{Cr}^{2+}(a q)+\mathrm{Sn}^{2+}(a q) & \longrightarrow \mathrm{Sn}(s)+\mathrm{Cr}^{3+}(a q)
\end{aligned}
$$

21.141 You are given the following three half-reactions:
(1) $\mathrm{Fe}^{3+}(a q)+\mathrm{e}^{-} \rightleftharpoons \mathrm{Fe}^{2+}(a q)$
(2) $\mathrm{Fe}^{2+}(a q)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{Fe}(s)$
(3) $\mathrm{Fe}^{3+}(a q)+3 \mathrm{e}^{-} \rightleftharpoons \mathrm{Fe}(s)$
(a) Use $E_{\text {half-cell }}^{\circ}$ values for (1) and (2) to find $E_{\text {half-cell }}^{\circ}$ for (3).
(b) Calculate $\Delta G^{\circ}$ for (1) and (2) from their $E_{\text {half-cell }}^{\circ}$ values.
(c) Calculate $\Delta G^{\circ}$ for (3) from (1) and (2).
(d) Calculate $E_{\text {half-cell }}^{\circ}$ for (3) from its $\Delta G^{\circ}$.
(e) Heyahisaheretationship between the $E_{\text {half-cell }}^{\circ}$ values for (1) and (2) and the $E_{\text {half-cell }}^{\circ}$ value for (3)?
21.142 Use the half-reaction method to balance the equation for the conversion of ethanol to acetic acid in acid solution:

$$
\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}+\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-} \longrightarrow \mathrm{CH}_{3} \mathrm{COOH}+\mathrm{Cr}^{3+}
$$

21.143 When zinc is refined by electrolysis, the desired halfreaction at the cathode is

$$
\mathrm{Zn}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Zn}(s)
$$

A competing reaction, which lowers the yield, is the formation of hydrogen gas:

$$
2 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(g)
$$

If $91.50 \%$ of the current flowing results in zinc being deposited, while $8.50 \%$ produces hydrogen gas, how many liters of $\mathrm{H}_{2}$, measured at STP, form per kilogram of zinc?
21.144 A chemist designs an ion-specific probe for measuring $\left[\mathrm{Ag}^{+}\right]$in an NaCl solution saturated with AgCl . One half-cell has an Ag -wire electrode immersed in the unknown $\mathrm{AgCl}-$ saturated NaCl solution. It is connected through a salt bridge to the other half-cell, which has a calomel reference electrode [a platinum wire immersed in a paste of mercury and calomel $\left.\left(\mathrm{Hg}_{2} \mathrm{Cl}_{2}\right)\right]$ in a saturated KCl solution. The measured $E_{\text {cell }}$ is 0.060 V .
(a) Given the following standard half-reactions, calculate $\left[\mathrm{Ag}^{+}\right]$. Calomel: $\mathrm{Hg}_{2} \mathrm{Cl}_{2}(s)+2 \mathrm{e}^{-} \longrightarrow$

$$
2 \mathrm{Hg}(l)+2 \mathrm{Cl}^{-}(a q) \quad E^{\circ}=0.24 \mathrm{~V}
$$

Silver: $\mathrm{Ag}^{+}(a q)+\mathrm{e}^{-} \longrightarrow \operatorname{Ag}(s) \quad E^{\circ}=0.80 \mathrm{~V}$
(Hint: Assume $\left[\mathrm{Cl}^{-}\right]$is so high that it is essentially constant.)
(b) A mining engineer wants an ore sample analyzed with the $\mathrm{Ag}^{+}$-selective probe. After pretreating the ore sample, the chemist measures the cell voltage as 0.53 V . What is $\left[\mathrm{Ag}^{+}\right]$?
21.145 Use Appendix D to calculate the $K_{\mathrm{sp}}$ of AgCl .
21.146 Black-and-white photographic film is coated with silver halides. Because silver is expensive, the manufacturer monitors the $\mathrm{Ag}^{+}$content of the waste stream, $\left[\mathrm{Ag}^{+}\right]_{\text {waste }}$, from the plant with an $\mathrm{Ag}^{+}$-selective electrode at $25^{\circ} \mathrm{C}$. A stream of known $\mathrm{Ag}^{+}$concentration, $\left[\mathrm{Ag}^{+}\right]_{\text {standard }}$, is passed over the electrode in turn with the waste stream and the data recorded by a computer. (a) Write the equations relating the nonstandard cell potential to the standard cell potential and $\left[\mathrm{Ag}^{+}\right]$for each solution.
(b) Combine these into a single equation to find $\left[\mathrm{Ag}^{+}\right]_{\text {waste }}$.
(c) Rewrite the equation from part (b) to find $\left[\mathrm{Ag}^{+}\right]_{\text {waste }}$ in $\mathrm{ng} / \mathrm{L}$.
(d) If $E_{\text {waste }}$ is 0.003 V higher than $E_{\text {standard }}$, and the standard solution contains $1000 . \mathrm{ng} / \mathrm{L}$, what is $\left[\mathrm{Ag}^{+}\right]_{\text {waste }}$ ?
(e) Rewrite the equation in part (b) to find $\left[\mathrm{Ag}^{+}\right]_{\text {waste }}$ for a system in which $T$ changes and $T_{\text {waste }}$ and $T_{\text {standard }}$ may be different.
21.147 Calculate the $K_{\mathrm{f}}$ of $\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}{ }^{+}$from

$$
\begin{array}{cl}
\mathrm{Ag}^{+}(a q)+\mathrm{e}^{-} \rightleftharpoons \mathrm{Ag}(s) & E^{\circ}=0.80 \mathrm{~V} \\
\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}^{+}(a q)+\mathrm{e}^{-} \rightleftharpoons \mathrm{Ag}(s)+2 \mathrm{NH}_{3}(a q) & E^{\circ}=0.37 \mathrm{~V}
\end{array}
$$

21.148 Even though the toxicity of cadmium has become a concern, nickel-cadmium (nicad) batteries are still used commonly in many devices. The overall cell reaction is

$$
\mathrm{Cd}(s)+2 \mathrm{NiO}(\mathrm{OH})(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \underset{2 \mathrm{Ni}(\mathrm{OH})(s)+\mathrm{Cd}(\mathrm{OH})_{2}(s)}{\longrightarrow}
$$

A certain nicad battery weighs 18.3 g and has a capacity of $300 . \mathrm{mA} \cdot \mathrm{h}$ (that is, the cell can store charge equivalent to a current of $300 . \mathrm{mA}$ flowing for 1 h ).
(a) What is the capacity of this cell in coulombs?
(b) What mass of reactants is needed to deliver $300 . \mathrm{mA} \cdot \mathrm{h}$ ?
(c) What percentage of the cell mass consists of reactants? $\mathbf{F}^{\prime}$
21.149 The zinc-air battery is a less expensive atternative for silver batteries in hearing aids. The cell reaction is

$$
2 \mathrm{Zn}(s)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{ZnO}(s)
$$

A new battery weighs 0.275 g . The zinc accounts for exactly $\frac{1}{10}$ of the mass, and the oxygen does not contribute to the mass because it is supplied by the air.
(a) How much electricity (in C) can the battery deliver?
(b) How much free energy (in J ) is released if $E_{\text {cell }}$ is 1.3 V ?
21.150 Use Appendix D to create an activity series of $\mathrm{Mn}, \mathrm{Fe}, \mathrm{Ag}$, $\mathrm{Sn}, \mathrm{Cr}, \mathrm{Cu}, \mathrm{Ba}, \mathrm{Al}, \mathrm{Na}, \mathrm{Hg}, \mathrm{Ni}, \mathrm{Li}, \mathrm{Au}, \mathrm{Zn}$, and Pb . Rank these metals in order of decreasing reducing strength, and divide them into three groups: those that displace $\mathrm{H}_{2}$ from water, those that displace $\mathrm{H}_{2}$ from acid, and those that cannot displace $\mathrm{H}_{2}$.
21.151 Both Ti and $V$ are reactive enough to displace $\mathrm{H}_{2}$ from water. The difference in their $E_{\text {half-cell }}^{\circ}$ values is 0.43 V . Given $\mathrm{V}(s)+\mathrm{Cu}^{2+}(a q) \longrightarrow \mathrm{V}^{2+}(a q)+\mathrm{Cu}(s) \quad \Delta G^{\circ}=-298 \mathrm{~kJ} / \mathrm{mol}$ use Appendix D to calculate the $E_{\text {half-cell }}^{\circ}$ values for V and Ti .
21.152 For the reaction
$\mathrm{S}_{4} \mathrm{O}_{6}{ }^{2-}(a q)+2 \mathrm{I}^{-}(a q) \longrightarrow \mathrm{I}_{2}(s)+\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}(a q)$
$\Delta G^{\circ}=87.8 \mathrm{~kJ} / \mathrm{mol}$
(a) Identify the oxidizing and reducing agents. (b) Calculate $E_{\text {cell- }}^{\circ}$ (c) For the reduction half-reaction, write a balanced equation, give the oxidation number of each element, and calculate $E_{\text {half-cell }}^{\circ}$
21.153 Two concentration cells are prepared, both with 90.0 mL of $0.0100 \mathrm{M} \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}$ and a Cu bar in each half-cell.
(a) In the first concentration cell, 10.0 mL of $0.500 \mathrm{NH}_{3}$ is added to one half-cell; the complex ion $\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}{ }^{2+}$ forms, and $E_{\text {cell }}$ is 0.129 V . Calculate $K_{\mathrm{f}}$ for the formation of the complex ion.
(b) Calculate $E_{\text {cell }}$ when an additional 10.0 mL of $0.500 \mathrm{M} \mathrm{H}_{3}$ is added.
(c) In the second concentration cell, 10.0 mL of 0.500 M NaOH is added to one half-cell; the precipitate $\mathrm{Cu}(\mathrm{OH})_{2}$ forms $\left(K_{\text {sp }}=\right.$ $2.2 \times 10^{-20}$ ). Calculate $E_{\text {cell }}^{\circ}$.
(d) What would the molarity of NaOH have to be for the addition of 10.0 mL to result in an $E_{\text {cell }}^{\circ}$ of 0.340 V ?
21.154 Two voltaic cells are to be joined so that one will run the other as an electrolytic cell. In the first cell, one half-cell has Au foil in $1.00 \mathrm{M} \mathrm{Au}\left(\mathrm{NO}_{3}\right)_{3}$, and the other half-cell has a Cr bar in $1.00 \mathrm{MCr}\left(\mathrm{NO}_{3}\right)_{3}$. In the second cell, one half-cell has a Co bar in $1.00 \mathrm{M} \mathrm{Co}\left(\mathrm{NO}_{3}\right)_{2}$, and the other half-cell has a Zn bar in $1.00 \mathrm{M} \mathrm{Zn}\left(\mathrm{NO}_{3}\right)_{2}$. (a) Calculate $E_{\text {cell }}^{\circ}$ for each cell. (b) Calculate the total potential if the two cells are connected as voltaic cells in series. (c) When the electrode wires are switched in one of the cells, which cell will run as the voltaic cell and which as the electrolytic cell? (d) Which metal ion is being reduced in each cell? (e) If 2.00 g of metal plates out in the voltaic cell, how much metal ion plates out in the electrolytic cell?
21.155 A voltaic cell has one half-cell with a Cu bar in a 1.00 M $\mathrm{Cu}^{2+}$ salt, and the other half-cell with a Cd bar in the same volume of a $1.00 M \mathrm{Cd}^{2+}$ salt. (a) Find $E_{\text {cell }}^{\circ}, \Delta G^{\circ}$, and $K$. (b) As the cell operates, $\left[\mathrm{Cd}^{2+}\right]$ increases; find $E_{\text {cell }}$ and $\Delta G$ when $\left[\mathrm{Cd}^{2+}\right]$ is $1.95 M$. (c) Find $E_{\text {cell }}, \Delta G$, and $\left[\mathrm{Cu}^{2+}\right]$ at equilibrium.
21.156 Gasoline is a mixture of hydrocarbons, but the heat released when it burns is close to that of octane, $\mathrm{C}_{8} \mathrm{H}_{18}(l)\left(\Delta H_{\mathrm{f}}^{\circ}=\right.$ $-250.1 \mathrm{~kJ} / \mathrm{mol}$ ). As an alternative to gasoline, research is underway to use $\mathrm{H}_{2}$ from the electrolysis of water in fuel cells to power cars. (a) Calculate $\Delta H^{\circ}$ when 1.00 gal of gasoline ( $d=0.7028 \mathrm{~g} / \mathrm{mL}$ )

EIburnstopfote carbon dioxide gas and water vapor.
(b) How many liters of $\mathrm{H}_{2}$ at $25^{\circ} \mathrm{C}$ and 1.00 atm must burn to produce this quantity of energy?
(c) How long would it take to produce this amount of $\mathrm{H}_{2}$ by electrolysis with a current of $1.00 \times 10^{3} \mathrm{~A}$ at 6.00 V ?
(d) How much power in kilowatt $\cdot$ hours $(\mathrm{kW} \cdot \mathrm{h})$ is required to generate this amount of $\mathrm{H}_{2}$ ? $(1 \mathrm{~W}=1 \mathrm{~J} / \mathrm{s}, 1 \mathrm{~J}=1 \mathrm{C} \cdot \mathrm{V}$, and $1 \mathrm{~kW} \cdot \mathrm{~h}=3.6 \times 10^{6} \mathrm{~J}$.)
(e) If the cell is $88.0 \%$ efficient and electricity costs $0.950 \notin$ per $\mathrm{kW} \cdot \mathrm{h}$, what is the cost of producing the amount of $\mathrm{H}_{2}$ equivalent to 1.00 gal of gasoline?
21.157 Balance the following redox reactions:
(a) In acidic solution, xenon trioxide reacts with iodide ion to produce xenon gas, triiodide ion $\left(\mathrm{I}_{3}{ }^{-}\right)$, and water.
(b) In basic solution, the hydrogen xenate ion $\left(\mathrm{HXeO}_{4}{ }^{-}\right)$disproportionates to xenon gas, perxenate ion $\left(\mathrm{XeO}_{6}{ }^{4-}\right)$, water, and oxygen gas.
(c) In basic solution, bismuthate ion $\left(\mathrm{BiO}_{3}{ }^{-}\right)$reacts with manganese(II) ion to produce bismuth(III) and permanganate ions.
(d) In basic solution, oxygen difluoride reacts to produce fluoride ion, oxygen gas, and water.
(e) In acidic solution, manganese(IV) oxide reacts with sulfite ion to form manganese(II) ion, water, and dithionate ion $\left(\mathrm{S}_{2} \mathrm{O}_{6}{ }^{2-}\right)$.
(f) In one of the few reactions known for astatine, the oxidation of astinide ion by chlorine gas in acid solution produces astinate ion $\left(\mathrm{AtO}_{3}{ }^{-}\right)$and chloride ion.
21.158 If the $E_{\text {cell }}$ of the following cell is 0.915 V , what is the pH in the anode compartment?

$$
\operatorname{Pt}(s)\left|\mathrm{H}_{2}(1.00 \mathrm{~atm})\right| \mathrm{H}^{+}(a q) \| \mathrm{Ag}^{+}(0.100 \mathrm{M}) \mid \mathrm{Ag}(s)
$$

Essential Products from Industry In industrial plants around the world, concentrated NaCl solutions are used to produce millions of metric tons of two of the most important chemicals, $\mathrm{Cl}_{2}$ and NaOH . In this chapter, we apply concepts from several previous chapters to the practical side of chemistry-the ways in which we obtain and utilize the elements and their compounds.

### 22.5 Chemical Manufacturing:

 Two Case StudiesSulfuric Acid
The Chlor-Alkali Process

|n this chapter, we return to the periodic table, but from a new perspective. In Chapter 14, we considered the atomic, physical, and chemical behavior of the main-group elements. Here, we examine various elements from a practical viewpoint to learn how much of an element is present in nature, in what form it occurs, how organisms affect its distribution, and how we isolate it for our own use.

Remember that chemistry is, above all, a practical science, and its concepts were developed to address real-life problems: How do we isolate and recycle aluminum? How do we make iron stronger? How do we lower energy costs and increase yield in the production of sulfuric acid? How does fossil-fuel combustion affect the environmental cycling of carbon? Here, we apply concepts you learned from the chapters on kinetics, equilibrium, thermodynamics, and electrochemistry to explain chemical processes in nature and industry that influence our lives.

IN THIS CHAPTER . . . We first discuss the abundances and sources of elements on Earth, then consider how three essential elements-carbon, nitrogen, and phosphorus-cycle through the environment. After seeing where and in what forms elements are found, we focus on their isolation and utilization. We discuss general redox and metallurgical procedures for extracting an element from its ore and examine in detail the isolation and uses of certain key elements. The chapter ends with a close look at two of the most important processes in chemical manufacturing: the production of sulfuric acid and the isolation of chlorine.

## Concepts \& Skills to Review before you study this chapter

- catalysts and reaction rate (Section 16.8)
- Le Châtelier's principle (Section 17.6)
- acid-base equilibria (Sections 18.3 and 18.9)
- solubility and complex-ion equilibria (Sections 19.3 and 19.4)
- temperature and reaction spontaneity (Section 20.3)
- free energy and equilibrium (Section 20.4)
- standard electrode potentials (Section 21.3)
- electrolysis of molten salts and aqueous salt solutions (Section 21.7)

### 22.1 HOW THE ELEMENTS OCCUR IN NATURE

To begin our examination of how we use the elements, let's take inventory of our elemental stock-the distribution and relative amounts of the elements on Earth, especially that thin outer portion of the planet that we can reach.

## Earth's Structure and the Abundance of the Elements

Any attempt to isolate an element must begin with a knowledge of its abundance, the amount of the element in a particular region of the natural world. The abundances of the elements on Earth and in its various regions are the result of the specific details of our planet's evolution.

Formation and Layering of Planet Earth About 4.5 billion years ago, vast clouds of cold gases and interstellar debris from exploded older stars gradually coalesced into the Sun and planets. At first, Earth was a cold, solid sphere of uniformly distributed elements and simple compounds. In the next billion years or so, heat from radioactive decay and virtually continuous meteor impacts raised the planet's temperature to around $10^{4} \mathrm{~K}$, sufficient to form an enormous molten mass. Any remaining gaseous elements, such as the cosmically abundant hydrogen and helium, were ejected into space.

As Earth cooled, chemical and physical processes resulted in its differentiation, the formation of regions of different composition and density. Differentiation gave Earth its layered internal structure, which consists of a dense $\left(10-15 \mathrm{~g} / \mathrm{cm}^{3}\right)$ core, composed of a molten outer core and a solid Moon-sized inner core. (Recent evidence has revealed remarkable properties of the inner core: it is nearly as hot as the surface of the Sun and spins within the molten outer core slightly faster than does Earth itself!) Around the core lies a thick homogeneous mantle, consisting of lower and upper portions, with an overall density of $4-6 \mathrm{~g} / \mathrm{cm}^{3}$. All the comings and goings of life take place on the thin heterogeneous crust (average density $=2.8 \mathrm{~g} / \mathrm{cm}^{3}$ ). Figure 22.1 on page 982 shows these layers and compares the abundances of some key elements in the universe, the whole Earth (actually core plus mantle only, which account for more than $99 \%$

Figure 22.1 Cosmic and terrestrial abundances of selected elements (mass percent). The mass percents of the elements are superimposed on a cutaway of Earth. The internal structure consists of a large core, thick mantle, and thin crust. The densities of these regions are indicated in the column heads. Blank abundance values mean either that reliable data are not available or that the value is less than $0.001 \%$ by mass. (Helium is not listed because it is not abundant on Earth, but it accounts for $24.0 \%$ by mass of the universe.)
of its mass), and Earth's three regions. (Because the deepest terrestrial sampling can penetrate only a few kilometers into the crust, some of these data represent extrapolations from meteor samples and from seismic studies of earthquakes.) Several points stand out:

1. Cosmic and whole-Earth abundances are very different, particularly for H .
2. The elements $\mathrm{O}, \mathrm{Si}, \mathrm{Fe}$, and Mg are abundant both cosmically and on Earth.

3. The core is particularly rich in the dense Group $8 \mathrm{~B}(8)$ through $8 \mathrm{~B}(10)$ metals: $\mathrm{Co}, \mathrm{Ni}$, and especially Fe , the most abundant element in the whole Earth.
4. Crustal abundances are very different from whole-Earth abundances. The crust makes up only $0.4 \%$ of Earth's mass, but has the largest share of nonmetals, metalloids, and light, active metals: $\mathrm{Al}, \mathrm{Ca}, \mathrm{Na}$, and K . The mantle contains smaller proportions of these, and the core has none. Oxygen is the most abundant element in the crust and mantle but is absent from the core.

These compositional differences in Earth's major layers, or phases, arose from the effects of thermal energy. When Earth was molten, gravity and convection caused more dense materials to sink and less dense materials to rise. Most of the Fe sank to form the core, or iron phase. In the light outer phase, oxygen combined with $\mathrm{Si}, \mathrm{Al}, \mathrm{Mg}$, and some Fe to form silicates, the material of rocks. This silicate phase later separated into the mantle and crust. The sulfide phase, intermediate in density and insoluble in the other two, consisted mostly of iron sulfide and mixed with parts of the silicate phase above and the iron phase below. Outgassing, the expulsion of trapped gases, produced a thin, primitive atmosphere, probably a mixture of water vapor (which gave rise to the oceans), carbon monoxide, and nitrogen (or ammonia).

The distribution of the remaining elements (discussed here using only the new group numbers) was controlled by their chemical affinity for one of the three phases. In general terms, as Figure 22.2 shows, elements with low or high electronegativity—active metals (Groups 1 through 5, Cr , and Mn ) and nonmetals (O, lighter members of Groups 13 to 15 , and all of Group 17) -tended to congregate in the silicate phase as ionic compounds. Metals with intermediate electronegativities (many from Groups 6 to 10) dissolved in the iron core. Lower-melting transition metals and many metals and metalloids in Groups 11 to 16 became concentrated in the sulfide phase.

Figure 22.2 Geochemical differentiation of the elements. During Earth's formation, elements became concentrated primarily in the atmosphere or one of three phases: silicate, sulfide, or iron.

The Impact of Life on Crustal Abundances At present, the crust is the only physically accessible portion of Earth, so only crustal abundances have practical significance. The crust is divided into solid, liquid, and gaseous portions called the lithosphere, hydrosphere, and atmosphere. Over billions of years, weathering and volcanic upsurges have dramatically altered threompasititneofthe crust. The biosphere, which consists of the fiving systems that have inhabited the planet, has been another major influence on crustal element composition and distribution.

When the earliest rocks were forming and the ocean basins filling with water, binary inorganic molecules in the atmosphere were reacting to form first simple, and then more complex, organic molecules. The energy for these (mostly) endothermic changes was supplied by lightning, solar radiation, geologic heating, and meteoric impact. In an amazingly short period of time, probably no more than 500 million years, the first organisms appeared. It took less than another billion years for these to evolve into simple algae that could derive metabolic energy from photosynthesis, converting $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ into organic molecules and releasing $\mathrm{O}_{2}$ as a byproduct. The importance of this process to crustal chemistry cannot be overstated. Over the next 300 million years, the atmosphere gradually became richer in $\mathrm{O}_{2}$, and oxidation became the major source of free energy in the crust and biosphere. Geologists mark this period by the appearance of Fe (III)containing minerals in place of the Fe (II)-containing minerals that had predominated (Figure 22.3A). Paleontologists see in it an explosion of $\mathrm{O}_{2}$-utilizing lifeforms, a few of which evolved into the organisms of today (Figure 22.3B).

Figure 22.3 Ancient effects of an $\mathrm{O}_{2}$-rich atmosphere. A, With the appearance of photosynthetic organisms and the resulting oxidizing environment, much of the iron(II) in minerals was oxidized to iron(III). These ancient banded-iron formations (red beds) from Michigan contain hematite, $\mathrm{Fe}_{2} \mathrm{O}_{3}$. $\mathbf{B}$, A fossil of Hallucigenia sparsa, one of the multicellular organisms found in the Burgess shale, British Columbia, Canada, whose appearance coincided with the increase in $\mathrm{O}_{2}$. Many of these organisms have no known modern descendants, having disappeared in a mass extinction at the end of the Cambrian Period about 505 million years ago.

Dolomite Mountains, Italy.

In addition to creating an oxidizing environment, organisms have had profound effects on the distribution of specific elements. Why, for instance, is the $\mathrm{K}^{+}$concentration of the oceans so much lower than the $\mathrm{Na}^{+}$concentration? Forming over eons from outgassed water vapor condensing into rain and streaming over the land, the oceans became complex ionic solutions of dissolved minerals with 30 times as much $\mathrm{Na}^{+}$as $\mathrm{K}^{+}$. There are two principal reasons for this difference. Clays, which make up a large portion of many soils, bind $\mathrm{K}^{+}$preferentially through an ion-exchange process. Even more importantly, plants require $\mathrm{K}^{+}$ for growth, absorbing dissolved $\mathrm{K}^{+}$that would otherwise wash down to the sea.

As another example, consider the enormous subterranean deposits of organic carbon. Buried deeply and decomposing under high pressure and temperature in the absence of free $\mathrm{O}_{2}$, ancient plants gradually turned into coal, and animals buried under similar conditions turned into petroleum. Crustal deposits of this organic carbon provide the fuels that move our cars, heat our homes, and electrify our cities. Moreover, carbon and calcium, the fifth most abundant element in the crust, occur together in vast sedimentary deposits all over the world as limestone, dolomite, marble, and chalk, the fossilized skeletal remains of early marine organisms (see photo).

Table 22.1 compares selected elemental abundances in the whole crust, the three crustal regions, and the human body, a representative portion of the biosphere. Note the quantities of the four major elements of life- $\mathrm{O}, \mathrm{C}, \mathrm{H}$, and N . Oxygen is either the first or second most abundant element in all cases. The biosphere contains large amounts of carbon in its biomolecules and large amounts of hydrogen as water. Nitrogen is abundant in the atmosphere as free $\mathrm{N}_{2}$ and in organisms as part of their proteins. Phosphorus and sulfur occur in exceptionally high amounts in organisms, too.

One striking difference among the lithosphere, hydrosphere, and biosphere (hanan) is in the abundanees bathe ramition metals vanadium through zinc.

Table 22.1 Abundances of Selected Elements in the Crust, Its Regions, and the Human Body as Representative of the Biosphere (Mass \%)

|  |  | Crustal Regions |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Element | Crust | Lithosphere | Hydrosphere | Atmosphere | Human |
| O | 49.5 | 45.5 | 85.8 | 23.0 | 65.0 |
| C | 0.08 | 0.018 | - | 0.01 | 18.0 |
| H | 0.87 | 0.15 | 10.7 | 0.02 | 10.0 |
| N | 0.03 | 0.002 | - | 75.5 | 3.0 |
| P | 0.12 | 0.11 | - | - | 1.0 |
| Mg | 1.9 | 2.76 | 0.13 | - | 0.50 |
| K | 2.4 | 1.84 | 0.04 | - | 0.34 |
| Ca | 3.4 | 4.66 | 0.05 | - | 2.4 |
| S | 0.06 | 0.034 | - | - | 0.26 |
| Na | 2.6 | 2.27 | 1.1 | - | 0.14 |
| Cl | 0.19 | 0.013 | 2.1 | - | 0.15 |
| Fe | 4.7 | 6.2 | - | - | 0.005 |
| Zn | 0.013 | 0.008 | - | - | 0.003 |
| Cr | 0.02 | 0.012 | - | - | $3 \times 10^{-6}$ |
| Co | 0.003 | 0.003 | - | - | $3 \times 10^{-6}$ |
| Cu | 0.007 | 0.007 | - | - | $4 \times 10^{-4}$ |
| Mn | 0.09 | 0.11 | - | - | $1 \times 10^{-4}$ |
| Ni | 0.008 | 0.010 | - | - | $3 \times 10^{-6}$ |
| V | 0.015 | 0.014 | - | $3 \times 10^{-6}$ |  |

Their relatively insoluble oxides and sulfides make them much scarcer in water than on land. Yet organisms, which evolved in the seas, developed the ability to concentrate the trace amounts of these elements present in their aqueous environment. In every case, the biological concentration shows an increase of at least 100 -fold, with Mn increasing about 1000 -fold, and $\mathrm{Cu}, \mathrm{Zn}$, and Fe even more. Each of these elements performs an essential role in living systems (see Chemical Connections, pp. 1055-1056).

## Sources of the Elements

Given an element's abundance in a region of the crust, we must next determine its occurrence, or source, the form(s) in which the element exists. Practical considerations often determine the commercial source. Oxygen, for example, is abundant in all three crustal regions, but the atmosphere is its primary industrial source because it occurs there as the free element. Nitrogen and the noble gases (except helium) are also obtained from the atmosphere. Several other elements occur uncombined, formed in large deposits by prehistoric biological action; examples are sulfur in caprock salt domes and nearly pure carbon in coal. The relatively unreactive elements gold and platinum also occur in an uncombined (native) state.

The overwhelming majority of elements, however, occur in ores, natural compounds or mixtures of compounds from which an element can be extracted by economically feasible means (see photo). The phrase "economically feasible" refers to an important point: the financial costs of mining, isolating, and purifying an element must be considered when choosing a process to obtain it.

Figure 22.4 shows the most useful sources of the elements. Alkali metal halides are ores for both of their component groups of elements. One example of how cost influences recovery concerns the feasibility of using silicates as ores. Even though many elements occur as silicatesmost of these Sourcesare very stable thermodynamically. Thus, the costof the energy required to process them prohibits their use-aside from silicon, only lithium and beryllium are obtained from their silicates. The Group $2 \mathrm{~A}(2)$ metals occur as carbonates in the marble and limestone of mountain ranges, although magnesium's great abundance in seawater makes that the preferred source, as we discuss later.

Figure 22.4 Sources of the elements. The major sources of most of the elements are shown. Although a few elements occur uncombined, most are obtained from their oxide or sulfide ores.

Deposit of borate (tufa), the ore of boron.

The ores of most industrially important metals are either oxides, which dominate the left half of the transition series, or sulfides, which dominate the right half of the transition series and a few of the main groups beyond. The reasons for the prominence of oxides and sulfides are complex and include processes of weathering, selective precipitation, and relative solubilities. Certain atomic properties are relevant as well. Elements toward the left side of the periodic table have lower ionization energies and electronegativities, so they tend to give up electrons or hold them loosely in bonds. The $\mathrm{O}^{2-}$ ion is small enough to approach a metal cation closely, which results in a high lattice energy for the oxide. In contrast, elements toward the right side have higher ionization energies and electronegativities. Thus, they tend to form bonds that are more covalent, which suits the larger, more polarizable $\mathrm{S}^{2-}$ ion.

## Section Summary

As the young Earth cooled, the elements became differentiated into a dense, metallic core, a silicate-rich mantle, and a low-density crust. - High abundances of light metals, metalloids, and nonmetals are concentrated in the crust, which consists of the lithosphere (solid), hydrosphere (liquid), and atmosphere (gaseous). • The biosphere (living systems) has affected crustal chemistry primarily by producing free $\mathrm{O}_{2}$, and thus an oxidizing environment. - Some elements occur in their native state, but most are combined in ores. The ores of most important metallic elements are oxides or sulfides.

### 22.2 THE CYCLING OF ELEMENTS THROUGH THE ENVIRONMENT

The distributions of many elements are in flux, changing at widely differing rates. ThepasicaP, chemied, andbiomgeat patesthat the atoms of an element take on their journey through regions of the crust constitute the element's environmental cycle. In this section, we consider the cycles for three important elementscarbon, nitrogen, and phosphorus-and highlight the effects of humans on them.

## The Carbon Cycle

Carbon is one of a handful of elements that appear in all three portions of Earth's crust. In the lithosphere, it occurs in elemental form as graphite and diamond, in fully oxidized form in carbonate minerals, in fully reduced form in petroleum hydrocarbons, and in complex mixtures, such as coal and living matter. In the hydrosphere, it occurs in living matter, in carbonate minerals formed by the action of coral-reef organisms, and in dissolved $\mathrm{CO}_{2}$. In the atmosphere, it occurs principally in gaseous $\mathrm{CO}_{2}$, a minor but essential component that exists in equilibrium with the aqueous fraction.

Figure 22.5 depicts the complex interplay of the carbon sources and the considerable effect of the biosphere on the element's environmental cycle. It provides an estimate of the size of each source and, where reliable numbers exist, the amount of carbon moving annually between sources. Some key points to note are

- The portions of the cycle are linked by the atmosphere-one link between oceans and air, the other between land and air. The $2.6 \times 10^{12}$ metric tons of $\mathrm{CO}_{2}$ in air cycles through the oceans and atmosphere about once every 300 years but spends a much longer time in carbonate minerals.
- Atmospheric $\mathrm{CO}_{2}$ accounts for a tiny fraction ( $0.003 \%$ ) of crustal carbon, but the atmosphere is the prime mover of carbon through the other regions. Estimates indicate that a $\mathrm{CO}_{2}$ molecule spends, on average, 3.5 years in the atmosphere.

Figure 22.5 The carbon cycle. The major sources and changes in carbon distribution are shown. Note that the atmosphere is the major conduit of carbon between land and sea and that $\mathrm{CO}_{2}$ becomes fixed through the action of organisms. Numbers in boxes refer to the
size of the source; numbers along arrows refer to the annual movement of the element from source to source. Values are in $10^{9}$ metric tons of $C$ (1 metric ton $=1000 \mathrm{~kg}=1.1$ tons).

- The land and oceans are also in contact with the largest sources of carbon, which are effectively immobilized as carbonates, coal, and oil in the rocky sediment beneath the soil.
- The biological processes of photosynthesis, respiration, and decay are major factors in the carbon cycle. Fixation is the process of converting a gaseous substance into a condensed, more usable form. Via photosynthesis, marine plankton and terrestrial plants use sunlight to fix atmospheric $\mathrm{CO}_{2}$ into carbohydrates. Plants release $\mathrm{CO}_{2}$ by respiration at night and, much more slowly, when they decay. Animals eat the plants and release $\mathrm{CO}_{2}$ by respiration and in their decay.
- Natural fires and volcanoes also release $\mathrm{CO}_{2}$ into the air.

For hundreds of millions of years, the cycle has maintained a relatively constant amount of atmospheric $\mathrm{CO}_{2}$. The tremendous growth of human industry over the past century and a half, and especially since World War II, has shifted this natural balance by increasing atmospheric $\mathrm{CO}_{2}$. The principal cause of this increase is the combustion of coal, wood, and oil for fuel and for the thermal decomposition of limestone to make cement, coupled with the simultaneous clearing of vast stretches of forest and jungle for lumber, paper, and agriculture. With the 1990s the hottest decade ever recorded, evidence is mounting that these activities are creating one of the most dire environmental changes in human historyglobal warming through the greenhouse effect (see Chemical Connections, p. 257). Higher temperatures, alterations in dry and rainy seasons, melting of polar ice, and increasing ocean acidity, with associated changes in carbonate equilibria, are some of the results currently being observed. Nearly all environmental and science policy experts are pressing for the immediate adoption of a program that combines conservation of carbon-based fuels, an end to deforestation, and development of alternative energy sources.

## The Nitrogen Cycle

In contrast to the carbon cycle, the nitrogen cycle includes a direct interaction of land and sea (Figure 22.6). All nitrites and nitrates are soluble, so rain and runoff contribute huge amounts of nitrogen to lakes, rivers, and oceans. Human activity, in the form of fertilizer production and use, plays a major role in this cycle.

Like carbon dioxide, atmospheric nitrogen must be fixed to be used by organisms. However, whereas $\mathrm{CO}_{2}$ can be incorporated by plants in either its gaseous or aqueous form, the great stability of $\mathrm{N}_{2}$ prevents plants from using it directly. Fixation of $\mathrm{N}_{2}$ requires a great deal of energy and occurs through atmospheric, industrial and biolpacal processesincer

1. Atmospheric fixation. Lightning brings about the high-temperature endothermic reaction of $\mathrm{N}_{2}$ and $\mathrm{O}_{2}$ to form NO , which is then oxidized by ozone exothermically to $\mathrm{NO}_{2}$ :

$$
\begin{aligned}
\mathrm{N}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}(g) & \Delta H^{\circ}=180.6 \mathrm{~kJ} \\
\mathrm{NO}(g)+\mathrm{O}_{3}(g) \longrightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g) & \Delta H^{\circ}=-200.1 \mathrm{~kJ}
\end{aligned}
$$

During the day, $\mathrm{NO}_{2}$ reacts with hydroxyl radical to form $\mathrm{HNO}_{3}$ :

$$
\mathrm{NO}_{2}(g)+\mathrm{HO} \cdot(g) \longrightarrow \mathrm{HNO}_{3}(g)
$$

At night, a multistep reaction between $\mathrm{NO}_{2}$ and ozone is involved. In either case, rain dissociates the nitric acid, and $\mathrm{NO}_{3}{ }^{-}(a q)$ enters both sea and land to be utilized by plants.
2. Industrial fixation. Most human-caused fixation occurs industrially during ammonia synthesis via the Haber process (see Chemical Connections, pp. 771772). The process takes place on an enormous scale: on a mole basis, $\mathrm{NH}_{3}$ ranks first among compounds in amount produced. Some of this $\mathrm{NH}_{3}$ is converted to $\mathrm{HNO}_{3}$ in the Ostwald process (Chapter 14, p. 600), but most is used as fertilizer, either directly or in the form of urea and ammonium salts (sulfate, phosphate, and nitrate), which enter the biosphere as they are taken up by plants (item 3 below). In recent decades, high-temperature combustion in electric power plants and in car, truck, and plane engines has become an important contributor to total fixed nitrogen, mainly because of the enormous rise in vehicle traffic. High engine operating temperatures mimic lightning to form NO from the air taken in to burn the hydrocarbon fuel. The NO in exhaust gases reacts to form nitric acid in the atmosphere, which adds to the nitrate load that reaches the ground.

The overuse of fertilizers and automobiles presents an increasingly serious water pollution problem in many areas. Leaching of the land by rain causes nitrate from fertilizer use and vehicle operation to enter natural waters (lakes, rivers, and

Figure 22.6 The nitrogen cycle. The major source of nitrogen, $\mathrm{N}_{2}$, is fixed atmospherically, industrially, and biologically. Various types of bacteria are indispensable throughout the cycle. Numbers in boxes
are in $10^{9}$ metric tons of N and refer to the size of the source; numbers along arrows are in $10^{6}$ metric tons of N and refer to the annual movement of the element between sources.
coastal estuaries) and cause eutrophication, the depletion of $\mathrm{O}_{2}$ and the death of aquatic animal life from excessive algal and plant growth and decay. Excess nitrate also spoils nearby drinkable water.
3. Biological fixation. The biological fixation of atmospheric $\mathrm{N}_{2}$ occurs in blue-green algae and in nitrogen-fixing bacteria that live on the roots of leguminous plants (such as peas, alfalfa, and clover). On a planetary scale, these microbial processes dwarf the previous two, fixing more than seven times as much nitrogen as the atmosphere and six times as much as industry. Root bacteria fix $\mathrm{N}_{2}$ by reducing it to $\mathrm{NH}_{3}$ and $\mathrm{NH}_{4}{ }^{+}$through the action of enzymes that contain the transition metal molybdenum at their active site. Enzymes in other soil bacteria catalyze the multistep oxidation of $\mathrm{NH}_{4}{ }^{+}$to $\mathrm{NO}_{2}{ }^{-}$and finally $\mathrm{NO}_{3}{ }^{-}$, which the plants reduce again to make their proteins. When the plants die, still other soil bacteria oxidize the proteins to $\mathrm{NO}_{3}{ }^{-}$.

Animals eat the plants, use the plant proteins to make their own proteins, and excrete nitrogenous wastes, such as urea $\left[\left(\mathrm{H}_{2} \mathrm{~N}\right)_{2} \mathrm{C}=\mathrm{O}\right]$. The nitrogen in the proteins is released when the animals die and decay, and is converted by soil bacteria to $\mathrm{NO}_{2}{ }^{-}$and $\mathrm{NO}_{3}{ }^{-}$again. This central pool of inorganic nitrate has three main fates: some enters marine and terrestrial plants, some enters the enormous sediment store of mineral nitrates, and some is reduced by denitrifying bacteria to $\mathrm{NO}_{2}{ }^{-}$and then reduced further to $\mathrm{N}_{2} \mathrm{O}$ and $\mathrm{N}_{2}$, which re-enter the atmosphere to complete the cycle.

Phosphorus from Outer Space Although most phosphate occurs in the rocks formed by geological activity on Earth, a sizeable amount arrived here from outer space and continues to do so. About 100 metric tons of meteorites enter our atmosphere each day. With an average P content of $0.1 \%$ by mass, they contribute about 36 metric tons of $P$ per year. Over Earth's 4.6-billion-year lifetime, about $10^{11}$ metric tons of P has arrived from extraterrestrial sources!

## The Phosphorus Cycle

Virtually all the mineral sources of phosphorus contain the phosphate group, $\mathrm{PO}_{4}{ }^{3-}$. The most commercially important ores are apatites, compounds of general formula $\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{X}$, where X is usually $\mathrm{F}, \mathrm{Cl}$, or OH . The cycling of phosphorus through the environment involves three interlocking subcycles, illustrated in Figure 22.7. Two rapid biological cycles-a land-based cycle completed in a matter of years and a water-based cycle completed in weeks to years-are superimposed on an inorganic cycle that takes millions of years to complete. Unlike the carbon and nitrogen cycles, the phosphorus cycle has no gaseous component and thus does not involve the atmosphere.

The Inorganic Cycle Most phosphate rock formed when Earth's lithosphere solidified. The most important components of this material are nearly insoluble phosphate salts:

$$
\begin{aligned}
K_{\mathrm{sp}} \text { of } \mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2} & \approx 10^{-29} \\
K_{\text {sp }} \text { of } \mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{OH} & \approx 10^{-51} \\
K_{\text {sp }} \text { of } \mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F} & \approx 10^{-60}
\end{aligned}
$$

Weathering slowly leaches phosphates from the soil and carries the ions through rivers to the sea. Plants in the land-based biological cycle speed this process. In the ocean, some phosphate is absorbed by organisms in the water-based biological cycle, but the majority is precipitated again by $\mathrm{Ca}^{2+}$ ion and deposited on the continental shelf. Geologic activity lifts the continental shelves, returning the phosphate to the land.

The Land-Based Biological Cycle The biological cycles involve the incorporation of phosphate into organisms (biomolecules, bones, teeth, and so forth) and the retaseanphosphathrough theiaexetonland decay. In the land-based cycle, plants continually remove phosphate from the inorganic cycle. Recall that there are three phosphate oxoanions, and they exist in equilibrium in the aqueous environment:

$$
\begin{aligned}
\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-} \rightleftharpoons & \mathrm{HPO}_{4}{ }^{2-} \rightleftharpoons \\
& +\mathrm{HO}^{+}{ }^{3-} \\
& +\mathrm{H}^{+}
\end{aligned}
$$

In topsoil, phosphates occur as insoluble compounds of $\mathrm{Ca}^{2+}, \mathrm{Fe}^{3+}$, and $\mathrm{Al}^{3+}$. Because plants can absorb only the water-soluble dihydrogen phosphate, they have evolved the ability to secrete acids near their roots to convert the insoluble salts gradually into the soluble ion:

$$
\begin{array}{r}
\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s \text {; soil })+4 \mathrm{H}^{+}(\text {aq; secreted by plants }) \longrightarrow \\
3 \mathrm{Ca}^{2+}(a q)+2 \mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}(\text {aq; absorbed by plants })
\end{array}
$$

Animals that eat the plants excrete soluble phosphate, which is used in turn by newly growing plants. As the plants and animals excrete, die, and decay, some phosphate is washed into rivers and from there to the ocean. Most of the $2 \mathrm{mil}-$ lion metric tons of phosphate that washes from land to sea each year comes from biological decay. Thus, the biosphere greatly increases the movement of phosphate from lithosphere to hydrosphere.

The Water-Based Biological Cycle Various phosphate oxoanions continually enter the aquatic environment. Studies that incorporate trace amounts of radioactive phosphorus into $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}$and monitor its uptake show that, within 1 minute, $50 \%$ of the ion is taken up by photosynthetic algae, which use it to synthesize

Figure 22.7 The phosphorus cycle. The inorganic subcycle (purple arrows), water-based biological subcycle (blue arrows), and land-based biological subcycle (yellow arrows) interact through ero-
sion and through the growth and decay of organisms. The phosphorus cycle has no gaseous component.

Enhancer
their biomolecules (this synthesis is denoted by the top curved arrow in the upcoming equation). The overall process might be represented by the following equation:

$$
\begin{aligned}
& 106 \mathrm{CO}_{2}(g)+16 \mathrm{NO}_{3}{ }^{-}(a q)+\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}(a q)+122 \mathrm{H}_{2} \mathrm{O}(l)+17 \mathrm{H}^{+}(a q) \overbrace{\text { decay }}^{\text {synthesis }} \\
& \mathrm{C}_{106} \mathrm{H}_{263} \mathrm{O}_{110} \mathrm{~N}_{16} \mathrm{P}(a q ; \text { in algal cell fluid })+138 \mathrm{O}_{2}(g)
\end{aligned}
$$

(The complex formula on the right represents the total composition of algal biomolecules, not some particular compound.)

As on land, animals eat the plants and are eaten by other animals, and they all excrete phosphate, die, and decay (denoted by the bottom curved arrow in the preceding equation). Some of the released phosphate is used by other aquatic organisms, and some returns to the land when fish-eating animals (mostly humans and birds) excrete phosphate, die, and decay. In addition, some aquatic phosphate precipitates with $\mathrm{Ca}^{2+}$, sinks to the seabed, and returns to the long-term mineral deposits of the inorganic cycle.

Human Effects on Phosphorus Movement From prehistoric through preindustrial times, these interlocking phosphorus cycles were balanced. Modern human activity, however, alters the movement of phosphorus considerably. Our influence on the inorganic cycle is minimal, despite our annual removal of more than

V agent, a lethal nerve gas
Phosphorus Nerve Poisons Because phosphorus is essential for all organisms, its compounds have many biological actions. In addition to their widespread use as fertilizer, phosphorus compounds are also used as pesticides and as military nerve gases. In fact, these two types of substances often have similar structures (see above) and modes of action. Both types affect the target organism by inactivating an enzyme involved in muscle contraction. They bind an amino acid critical to the enzyme's function, allowing the muscle to contract but not relax; the effect on the organism-insect or human-is often fatal. Chemists have synthesized a nerve-gas antidote whose shape mimics the binding site of the enzyme. The drug binds the poison, removing it from the enzyme, and is excreted.

Figure 22.8 Industrial uses of phosphorus. The major end products from phosphate rock are shown, with box heights proportional to the amounts (mass \%) of phosphate rock used annually to make the end product. Over 100 million metric tons of phosphate rock is mined each year (100\%).

100 million metric tons of phosphate rock for a variety of uses (Figure 22.8). The end products of thisiomovat however have unbalanced the two biological cycles.

The imbalance arises from our overuse of soluble phosphate fertilizers, such as $\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{PO}_{4}\right)_{2}$ and $\mathrm{NH}_{4} \mathrm{H}_{2} \mathrm{PO}_{4}$, the end products of about $85 \%$ of phosphate rock mined. Some fertilizer finds its way into rivers, lakes, and oceans to enter the water-based cycle. Much larger pollution sources, however, are the crops grown with the fertilizer and the detergents made from phosphate rock. The great majority of this phosphate arrives eventually in cities as crops, as animals that were fed crops, and as consumer products, such as the tripolyphosphates in detergents. Human garbage, excrement, wash water with detergents, and industrial wastewater containing phosphate return through sewers to the aquatic system. This human contribution equals the natural contribution-another 2 million metric tons of phosphate per year. The increased concentration in rivers and lakes causes eutrophication, which robs the water of $\mathrm{O}_{2}$ so that it cannot support life. Such "dead" rivers and lakes are no longer usable for fishing, drinking, or recreation.

As early as 1912, a chemical solution to this problem was tried in Switzerland, where the enormous Lake Zurich had been choked with algae and become devoid of fish because of the release of human sewage. Treatment with $\mathrm{FeCl}_{3}$ precipitated enough phosphate to return the lake gradually to its natural state. Soluble aluminum compounds have the same effect:

$$
\begin{aligned}
& \mathrm{FeCl}_{3}(a q)+\mathrm{PO}_{4}{ }^{3-}(a q) \longrightarrow \mathrm{FePO}_{4}(s)+3 \mathrm{Cl}^{-}(a q) \\
& \mathrm{KAl}\left(\mathrm{SO}_{4}\right)_{2} \cdot 12 \mathrm{H}_{2} \mathrm{O}(a q)+\mathrm{PO}_{4}^{3-}(a q) \longrightarrow \\
& \mathrm{AlPO}_{4}(s)+\mathrm{K}^{+}(a q)+2 \mathrm{SO}_{4}{ }^{2-}(a q)+12 \mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
$$

After several lakes in the United States became polluted in this way, phosphates in detergents were drastically reduced, and stringent requirements for sewage treatment, including tertiary treatments to remove phosphate (see Chemical Connections, pp. 541-542) were put into effect. Lake Erie, which was severely polluted by the late 1960 s and early 1970 s, was the target of a program to reduce phosphates and is today relatively clean and restocked with fish.

#### Abstract

Section Summary The environmental distribution of many elements changes cyclically with time and is affected in major ways by organisms. - Carbon occurs in all three regions of Earth's crust, with atmospheric $\mathrm{CO}_{2}$ linking the other two regions. Photosynthesis and decay of organisms alter the amount of carbon in the land and oceans. Human activity has increased atmospheric $\mathrm{CO}_{2}$. Nitrogen is fixed by lightning, by industry, and primarily by microorganisms. When plants decay, bacteria decompose organic nitrogen and eventually return $\mathrm{N}_{2}$ to the atmosphere. Through extensive use of fertilizers, humans have added excess nitrogen to freshwaters. - The phosphorus cycle has no gaseous component. Inorganic phosphates leach slowly into land and water, where biological cycles interact. When plants and animals decay, they release phosphate to natural waters, where it is then absorbed by other plants and animals. Through overuse of phosphate fertilizers and detergents, humans double the amount of phosphorus entering aqueous systems.

### 22.3 METALLURGY: EXTRACTING A METAL FROM ITS ORE

Metallurgy is the branch of materials science concerned with the extraction and utilization of metals. In this section, we discuss the general procedures for isolating metals and, occasionally, the nonmetals that are found in their ores. The extraction process applies one or more of these three types of metallurgy: pyrometallurgy uses heat to obtain the metal, electrometallurgy employs an electrochemical step, and hydrometallurgy relies on the metal's aqueous solution chemistry.

The extraction of an element begins with mining the ore. Most ores consist
 urally occurring, homogeneous, crystalline inorganic solid, with a well-defined composition. The gangue is the portion of the ore with no commercial value, such as sand, rock, and clay attached to the mineral. Table 22.2 lists the common mineral sources of some metals.

Humans have been removing metals from Earth's crust for thousands of years, so most of the known concentrated sources are long gone. In many cases, ores containing very low mass percents of a metal are all that remain, and these require elaborate-and ingenious-extraction methods. Nevertheless, the general procedure for extracting most metals (and many nonmetals) involves a few basic steps, described in the upcoming subsections and previewed in Figure 22.9.

| Table 2 Source | Common Mineral <br> Some Elements |
| :---: | :---: |
| Element | Mineral, Formula |
| Al | Gibbsite (in bauxite), <br> $\mathrm{Al}(\mathrm{OH})_{3}$ |
| Ba | Barite, $\mathrm{BaSO}_{4}$ |
| Be | Beryl, $\mathrm{Be}_{3} \mathrm{Al}_{2} \mathrm{Si}_{6} \mathrm{O}_{18}$ |
| Ca | Limestone, $\mathrm{CaCO}_{3}$ |
| Fe | Hematite, $\mathrm{Fe}_{2} \mathrm{O}_{3}$ |
| Hg | Cinnabar, HgS |
| Na | Halite, NaCl |
| Pb | Galena, PbS |
| Sn | Cassiterite, $\mathrm{SnO}_{2}$ |
| Zn | Sphalerite, ZnS |

## Pretreating the Ore

Following a crushing, grinding, or pulverizing step, which can be very expensive, pretreatment usually takes advantage of some physical or chemical difference to separate mineral from gangue. For magnetic minerals, such as magnetite $\left(\mathrm{Fe}_{3} \mathrm{O}_{4}\right)$, a magnet can remove the mineral and leave the gangue behind. Where large density differences exist, a cyclone separator is used; it blows high-pressure air through the pulverized mixture to separate the particles. The lighter silicate-rich

Figure 22.10 The cyclone separator. The pulverized ore enters at an angle, resulting in the more dense particles (mineral) hitting the walls and spiraling downward, while the less dense particles (silicate-rich gangue) are carried upward in a stream of air.

Figure 22.11 The flotation process. The pulverized ore is treated with an oil-detergent mixture, then stirred and aerated to create a froth that separates the detergent-coated mineral from the gangue. The mineral-rich froth is collected for further processing.

The picture of the prospector, alone but for his faithful mule, hunched over the bank of a mountain stream patiently panning for gold, is mostly a relic of old movies. However, the process is valid. It is based on the very large density difference between gold $\left(d=19.3 \mathrm{~g} / \mathrm{cm}^{3}\right)$ and sand $\left(d \approx 2.5 \mathrm{~g} / \mathrm{cm}^{3}\right)$. In ancient times, river sands were washed over a sheep's fleece to trap the gold grains, a practice historians think represents the origin of the Golden Fleece of Greek mythology.
gangue is blown away, while the denser mineral-rich particles hit the walls of the separator and fall through the open bottom (Figure 22.10).

In flotation, an oil-detergent mixture is stirred with the pulverized ore in water to form a slurry (Figure 22.11). Flotation takes advantage of the different abilities of the surfaces of mineral and of gangue to become wet in contact with water and detergent. Rapid mixing moves air bubbles through the mixture and produces an oily, mineral-rich froth that floats, while the silicate particles sink. Skimming, followed by solvent removal of the oil-detergent mixture, isolates the concentrated mineral fraction. Flotation is a key step in copper recovery.

Leaching is a hydrometallurgical process that selectively extracts the metal,
 ple of this technique, because nuggets of the precious metal are found only in museums nowadays. The crushed ore, which often contains as little as 25 ppm of gold, is contained in a plastic-lined pool, treated with a cyanide ion solution, and aerated. In the presence of $\mathrm{CN}^{-}$, the $\mathrm{O}_{2}$ in air oxidizes gold metal to $\operatorname{gold}(\mathrm{I})$ ion, $\mathrm{Au}^{+}$, which forms the soluble complex ion, $\mathrm{Au}(\mathrm{CN})_{2}{ }^{-}$:

$$
4 \mathrm{Au}(s)+\mathrm{O}_{2}(g)+8 \mathrm{CN}^{-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 4 \mathrm{Au}(\mathrm{CN})_{2}{ }^{-}(a q)+4 \mathrm{OH}^{-}(a q)
$$

(The method has become controversial in some areas because cyanide lost from the contained area enters streams and lakes, where it poisons fish and birds.)

## Converting Mineral to Element

After the mineral has been freed of debris and concentrated, it may undergo several chemical steps during its conversion to the element.
