Converting the Mineral to Another Compound First, the mineral is often converted to another compound, one that has more appropriate solubility properties, is easier to reduce, or is free of a troublesome impurity. Conversion to an oxide is common because oxides can be reduced easily. Carbonates are heated to convert them to the oxide:

$$
\mathrm{CaCO}_{3}(s) \xrightarrow{\Delta} \mathrm{CaO}(s)+\mathrm{CO}_{2}(g)
$$

Metal sulfides, such as ZnS , can be converted to oxides by roasting in air:

$$
2 \mathrm{ZnS}(s)+3 \mathrm{O}_{2}(g) \xrightarrow{\Delta} 2 \mathrm{ZnO}(s)+2 \mathrm{SO}_{2}(g)
$$

In most countries, hydrometallurgical methods are now used to avoid the atmospheric release of $\mathrm{SO}_{2}$ during roasting. One way of processing copper, for example, is by bubbling air through an acidic slurry of insoluble $\mathrm{Cu}_{2} \mathrm{~S}$, which completes both the pretreatment and conversion steps:

$$
2 \mathrm{Cu}_{2} \mathrm{~S}(s)+5 \mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q) \longrightarrow 4 \mathrm{Cu}^{2+}(a q)+2 \mathrm{SO}_{4}{ }^{2-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

Converting the Compound to the Element Through Chemical Redox The next step converts the new mineral form (usually an oxide) to the free element by either chemical or electrochemical methods. Let's consider the chemical methods first. In these processes, a reducing agent reacts directly with the compound. The most common reducing agents are carbon, hydrogen, and an active metal.

1. Reduction with carbon. Carbon, in the form of coke (a porous residue from incomplete combustion of coal) or charcoal, is a very common reducing agent. Heating an oxide with a reducing agent such as coke to obtain the metal is called smelting. Many metal oxides, such as zinc oxide and tin(IV) oxide, are smelted with carbon to free the metal, which may need to be condensed and solidified:

$$
\begin{aligned}
\mathrm{ZnO}(s)+\mathrm{C}(s) & \longrightarrow \mathrm{Zn}(g)+\mathrm{CO}(g) \\
\mathrm{SnO}_{2}(s)+2 \mathrm{C}(s) & \longrightarrow \mathrm{Sn}(l)+2 \mathrm{CO}(g)
\end{aligned}
$$

Several nonmetals that occur with positive oxidation states in minerals can be reduced with carbon as well. Phosphorus, for example, is produced from calcium phosphate:

$$
2 \mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s)+10 \mathrm{C}(s)+6 \mathrm{SiO}_{2}(s) \longrightarrow 6 \mathrm{CaSiO}_{3}(s)+10 \mathrm{CO}(g)+\mathrm{P}_{4}(s)
$$

(Metallic calcium is a much stronger reducing agent than carbon, so it is not formed.)

Low cost and ready availability explain why carbon is such a common reducing agent, and thermodynamic principles explain why it is such an effective one in many cases. Consider the standard free energy change $\left(\Delta G^{\circ}\right)$ for the reduction of $\operatorname{tin}(I V)$ oxide:

$$
\mathrm{SnO}_{2}(s)+2 \mathrm{C}(s) \longrightarrow \mathrm{Sn}(s)+2 \mathrm{CO}(g) \quad \Delta G^{\circ}=245 \mathrm{~kJ} \text { at } 25^{\circ} \mathrm{C}(298 \mathrm{~K})
$$

The magnitude and sign of $\Delta G^{\circ}$ indicate a highly nonspontaneous reaction for standard conditions at $25^{\circ} \mathrm{C}$. However, because solid C becomes gaseous CO , the
 $-T \Delta S^{\circ}$ term of $\Delta G^{\circ}$ becomes more negative with higher temperature (Section 20.3). As the temperature increases, $\Delta G^{\circ}$ decreases, and at a high enough temperature, the reaction becomes spontaneous $\left(\Delta G^{\circ}<0\right)$. At $1000^{\circ} \mathrm{C}(1273 \mathrm{~K})$, for example, $\Delta G^{\circ}=-62.8 \mathrm{~kJ}$. The actual process is carried out at a temperature of around $1250^{\circ} \mathrm{C}(1523 \mathrm{~K})$, so $\Delta G^{\circ}$ is even more negative.

As you know, overall reactions often mask several intermediate steps. For instance, the reduction of $\operatorname{tin}(\mathrm{IV})$ oxide may begin with formation of $\operatorname{tin}$ (II) oxide:

$$
\begin{aligned}
\mathrm{SnO}_{2}(s)+\mathrm{C}(s) & \longrightarrow \mathrm{SnO}(s)+\mathrm{CO}(g) \\
\mathrm{SnO}(s)+\mathrm{C}(s) & \longrightarrow \mathrm{Sn}(l)+\mathrm{CO}(g)
\end{aligned}
$$

[Molten tin $(\mathrm{mp}=232 \mathrm{~K})$ is obtained at this temperature.] The second step may even be composed of others, in which CO , not C , is the actual reducing agent:

$$
\begin{aligned}
\mathrm{SnO}(s)+\mathrm{CO}(g) & \longrightarrow \mathrm{Sn}(l)+\mathrm{CO}_{2}(g) \\
\mathrm{CO}_{2}(g)+\mathrm{C}(s) & \rightleftharpoons z \mathrm{CO}(g)
\end{aligned}
$$

Other pyrometallurgical processes are similarly complex. Shortly, you'll see that the overall reaction for the smelting of iron is

$$
2 \mathrm{Fe}_{2} \mathrm{O}_{3}(s)+3 \mathrm{C}(s) \longrightarrow 4 \mathrm{Fe}(l)+3 \mathrm{CO}_{2}(g)
$$

However, the actual process is a multistep one with CO as the reducing agent. The advantage of CO over C is the far greater contact the gaseous reducing agent can make with the other reactant, which speeds the process.
2. Reduction with hydrogen. For oxides of some metals, especially some members of Groups $6 \mathrm{~B}(6)$ and $7 \mathrm{~B}(7)$, reduction with carbon forms metal carbides. These carbides are difficult to convert further, so other reducing agents are used. Hydrogen gas is used for less active metals, such as tungsten:

$$
\mathrm{WO}_{3}(s)+3 \mathrm{H}_{2}(g) \longrightarrow \mathrm{W}(s)+3 \mathrm{H}_{2} \mathrm{O}(g)
$$

One step in the purification of the metalloid germanium uses hydrogen:

$$
\mathrm{GeO}_{2}(s)+2 \mathrm{H}_{2}(g) \longrightarrow \mathrm{Ge}(s)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

Figure 22.12 The thermite reaction. This highly exothermic redox reaction uses powdered aluminum to reduce metal oxides.

Figure 22.13 The redox step in converting a mineral to the element. Most elements are reduced from the compound with carbon, a more active metal, or $\mathrm{H}_{2}$.Uncombined in natureReduction of molten halide (or oxide) electrolyticallyReduction of halide with active metal (e.g., Na, Mg, Ca)Reduction of oxide/halide with Al or $\mathrm{H}_{2}$Reduction of oxide with C (coke or charcoal)Oxidation of anion (or oxoanion) chemically and/or electrolytically
3. Reduction with an active metal. When a metal might form an undesirable hydride, its oxide is reduced by a more active metal. In the thermite reaction, aluminum powder reduces the metal oxide in a spectacular exothermic reaction to give the molten metal (Figure 22.12). The reaction for chromium is

$$
\mathrm{Cr}_{2} \mathrm{O}_{3}(s)+2 \mathrm{Al}(s) \longrightarrow 2 \mathrm{Cr}(l)+\mathrm{Al}_{2} \mathrm{O}_{3}(s) \quad \Delta H^{\circ} \ll 0
$$

Reduction by a more active metal is also used in situations that do not involve an oxide. In the extraction of gold, after the pretreatment by leaching, the gold(I) complex ion is reduced with zinc to form the metal and a zinc complex ion:

$$
2 \mathrm{Au}(\mathrm{CN})_{2}{ }^{-}(a q)+\mathrm{Zn}(s) \longrightarrow 2 \mathrm{Au}(s)+\mathrm{Zn}(\mathrm{CN})_{4}{ }^{2-}(a q)
$$

In some cases, an active metal, such as calcium, is used to recover an even more active metal, such as rubidium, from its molten salt:

$$
\mathrm{Ca}(l)+2 \mathrm{RbCl}(l) \longrightarrow \mathrm{CaCl}_{2}(l)+2 \mathrm{Rb}(g)
$$

A similar process is used to recover sodium, as detailed in Section 22.4.
4. Oxidation with an active nonmetal. Just as chemical reduction of a mineral is used to obtain the metal, chemical oxidation of a mineral is sometimes used to obtain a nonmetal. A stronger oxidizing agent is used to remove electrons from the nonmetal anion to give the free nonmetal, as in the industrial production of iodine from concentrated brines by oxidation with chlorine gas:

$$
2 \mathrm{I}^{-}(a q)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{Cl}^{-}(a q)+\mathrm{I}_{2}(s)
$$

## Converting the Compound to the Element Through Electrochemical Redox In

these processes, the mineral components are converted to the elements in an electrolytic cell (Section 21.7). Sometimes, the pure mineral, in the form of the molten halide or oxide, is used to prevent unwanted side reactions. The cation is reduced to the metal at the cathode, and the anion is oxidized to the nonmetal at the anode:

## Apago PDF BClhancBens $+\mathrm{Cl}_{2}(\mathrm{~g})$

High-purity hydrogen gas is prepared by electrochemical reduction:

$$
2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g)
$$

Specially designed cells separate the products to prevent recombination. Cost is a major factor in the use of electrolysis, and an inexpensive source of electricity is essential for large-scale methods. The current and voltage requirements depend on the electrochemical potential and any overvoltage effects. Figure 22.13 shows the most common step for obtaining each free element from its mineral.

## Refining and Alloying the Element

At this point in the isolation process, the element typically contains impurities from previous steps, so it must be refined. Then, once purified, metallic elements are often alloyed to improve their properties.
Refining (Purifying) the Element Refining is a purification procedure, often carried out by one of three common methods. An electrolytic cell is employed in electrorefining, in which the impure metal acts as the anode and a sample of the pure metal acts as the cathode. As the reaction proceeds, the anode slowly disintegrates, and the metal ions are reduced to deposit on the cathode. In some cases, the impurities, which fall beneath the disintegrating anode, are the source of several valuable and less abundant elements. (We examine the electrorefining of copper in Section 22.4.)

Metals with relatively low boiling points, such as zinc and mercury, are refined by distillation.

In the process of zone refining (see the Gallery, p. 533), impurities are removed from a bar of the element by concentrating them in a thin molten zone, while the purified element recrystallizes. Metalloids used in electronic semiconductors, such as silicon and germanium, must be zone refined to greater than $99.999999 \%$ purity.

Alloying the Purified Element An alloy is a metal-like mixture consisting of solid phases of two or more pure elements, a solid solution, or, in some cases, distinct intermediate phases (these alloys are sometimes referred to as intermetallic compounds). The separate phases are often so finely divided that they can only be distinguished microscopically. Alloying a metal with other metals (and, in some cases, nonmetals) is done to alter the metal's melting point and to enhance properties such as luster, conductivity, matbeabititg duetiing andretrehre...nceェ

Iron, probably the most important metal, is used only when it is alloyed. In pure form, it is soft and corrodes easily. However, when alloyed with carbon and other metals, such as Mo for hardness and Cr and Ni for corrosion resistance, it forms the various steels. Copper stiffens when zinc is added to make brass. Mercury solidifies when alloyed with sodium, and vanadium becomes extremely tough with some carbon added. Table 22.3 shows the composition and uses of some common alloys.

The simplest alloys, called binary alloys, contain only two elements. In some cases, the added element enters interstices, spaces between the parent metal atoms

| Table 22.3 | Some Familiar Alloys and Their Composition |  |
| :--- | :--- | :--- |
| Name | Composition (Mass \%) | Uses |
| Stainless steel | $73-79 \mathrm{Fe}, 14-18 \mathrm{Cr}, 7-9 \mathrm{Ni}$ | Cutlery, instruments |
| Nickel steel | $96-98 \mathrm{Fe}, 2-4 \mathrm{Ni}$ | Cables, gears |
| High-speed steels | $80-94 \mathrm{Fe}, 14-20 \mathrm{~W}$ (or 6-12 Mo) | Cutting tools |
| Permalloy | $78 \mathrm{Ni}, 22 \mathrm{Fe}$ | Ocean cables |
| Bronzes | $70-95 \mathrm{Cu}, 1-25 \mathrm{Zn}, 1-18 \mathrm{Sn}$ | Statues, castings |
| Brasses | $50-80 \mathrm{Cu}, 20-50 \mathrm{Zn}$ | Plating, ornamental |
|  |  | objects |
| Sterling silver | $92.5 \mathrm{Ag}, 7.5 \mathrm{Cu}$ | Jewelry, tableware |

Figure 22.14 Three binary alloys.

in the crystal structure (Section 12.6). In vanadium carbide, for instance, carbon atoms occupy holes of a face-centered cubic vanadium unit cell (Figure 22.14A). In other cases, the added element substitutes for parent atoms in the unit cell. In many types of brass, for example, relatively few zinc atoms substitute randomly for copper atoms in the face-centered cubic copper unit cell (see Figure 13.4A, p. 507). On the other hand, $\beta$-brass is an intermediate phase that crystallizes as the $\mathrm{Zn} / \mathrm{Cu}$ ratio approaches $1 / 1$ in a structure with a Zn atom surrounded by eight Cu atoms (Figure 22.14B). In one alloy of copper and gold, Cu atoms occupy the faces of a face-centered cube, and Au atoms lie at the corners (Figure 22.14C).

Atomic properties, including size, electron configuration, and number of valence electrons, determine which metals form stable alloys. Thus, transition metals having few $d$ electrons often form stable alloys with transition metals having many $d$ electrons. Thus, metals from the left half of the $d$ block [Groups 3B(3) to $5 \mathrm{~B}(5)$ ]often formalloys with metals from the right half [Groups $8 \mathrm{~B}(9)$ to
 electron-rich Ir , Pt , or Au ; an example is the very stable $\mathrm{ZrPt}_{3}$.

## Section Summary

Metallurgy involves mining an ore, separating it from debris, pretreating it to concentrate the mineral source, converting the mineral to another compound that is easier to process further, reducing this compound to the metal, purifying the metal, and in many cases, alloying it to obtain a more useful material.

### 22.4 TAPPING THE CRUST: ISOLATION AND USES OF SELECTED ELEMENTS

Once an element's abundance and sources are known and the metallurgical methods chosen, the isolation process begins. Obviously, the process depends on the physical and chemical properties of the source: we isolate an element that occurs uncombined in the air differently from one dissolved in the sea or one found in a rocky ore. In this section, we detail methods for recovering some important elements; pay special attention to the application of ideas from earlier chapters to these key industrial processes.

## Producing the Alkali Metals: Sodium and Potassium

The alkali metals are among the most reactive elements and thus are always found as ions in nature, either in solid minerals or in aqueous solution. In the laboratory, the free elements must be protected from contact with air (for example, by being stored under mineral oil) to prevent their immediate oxidation and to minimize the possibility of fires. The two most important alkali metals are sodium
and potassium. Their abundant, water-soluble compounds are used throughout industry and research, and the $\mathrm{Na}^{+}$and $\mathrm{K}^{+}$ions are essential to organisms.
Industrial Production of Sodium and Potassium The sodium ore is halite (largely NaCl ), which is obtained either by evaporation of concentrated salt solutions (brines) or by mining vast salt deposits formed from the evaporation of prehistoric seas. The Cheshire salt field in Britain, for example, is 60 km by 24 km by 400 m thick and contains more than $90 \% \mathrm{NaCl}$. Other large deposits occur in New Mexico, Michigan, New York, and Kansas.

The brine is evaporated to dryness, and the solid is crushed and fused (melted) for use in an electrolytic apparatus called the Downs cell (Figure 22.15). To reduce heating costs, the $\mathrm{NaCl}\left(\mathrm{mp}=801^{\circ} \mathrm{C}\right)$ is mixed with $1 \frac{1}{2}$ parts $\mathrm{CaCl}_{2}$ to form a mixture that melts at only $580^{\circ} \mathrm{C}$. Reduction of the metal ions to Na and Ca takes place at a cylindrical steel cathode, with the molten metals floating on the denser molten salt mixture. As they rise through a short collecting pipe, the liquid Na is siphoned off, while a higher melting $\mathrm{Na} / \mathrm{Ca}$ alloy solidifies and falls back into the molten electrolyte. Chloride ions are oxidized to $\mathrm{Cl}_{2}$ gas at a large anode within an inverted cone-shaped chamber. The cell design separates the metals from the $\mathrm{Cl}_{2}$ to prevent their explosive recombination. The $\mathrm{Cl}_{2}$ gas is collected, purified, and sold as a valuable byproduct.

Sylvite (mostly KCl ) is the major ore of potassium. The metal is too soluble in molten KCl to be prepared by a method similar to that for sodium. Instead, chemical reduction of $\mathrm{K}^{+}$ions by liquid Na is used. The method is based on atomic properties and the nature of equilibrium systems. Recall that an Na atom is smaller than a K atom, so it holds its outer electron more tightly, as the first ionization energies indicate: $\mathrm{IE}_{1}$ of $\mathrm{Na}=496 \mathrm{~kJ} / \mathrm{mol} ; \mathrm{IE}_{1}$ of $\mathrm{K}=419 \mathrm{~kJ} / \mathrm{mol}$. Thus, if the isolation method for K were based solely on this atomic property, Na
 very far toward products. An ingenious approach, which applies Le Châtelier's

A Plentiful Oceanic Supply of NaCl Will we ever run out of sodium chloride? Not likely. The rock-salt (halite) equivalent of NaCl in the world's oceans has been estimated at $1.9 \times 10^{7} \mathrm{~km}^{3}$, about $150 \%$ of the volume of North America above sea level. Or, looking at this amount another way: a row of $1-\mathrm{km}^{3}$ cubes of NaCl would stretch from Earth to the Moon 47 times! The photo shows evaporative salt beds near San Francisco Bay.

Firefighter with $\mathrm{KO}_{2}$ breathing mask.

| Table 22.4 | Important Minerals of Iron |
| :---: | :---: |
| Mineral Type | Mineral, Formula |
| Oxide | Hematite, $\mathrm{Fe}_{2} \mathrm{O}_{3}$ Magnetite, $\mathrm{Fe}_{3} \mathrm{O}_{4}$ Ilmenite, $\mathrm{FeTiO}_{3}$ |
| Carbonate Sulfide | Siderite, $\mathrm{FeCO}_{3}$ <br> Pyrite, $\mathrm{FeS}_{2}$ <br> Pyrrhotite, FeS |

principle, overcomes this drawback. The reduction is carried out at $850^{\circ} \mathrm{C}$, which is above the boiling point of K , so the equilibrium mixture contains gaseous K :

$$
\mathrm{Na}(l)+\mathrm{K}^{+}(l) \rightleftharpoons \mathrm{Na}^{+}(l)+\mathrm{K}(g)
$$

As the K gas is removed, the system shifts to produce more K . The gas is then condensed and purified by fractional distillation. The same general method (with Ca as the reducing agent) is used to produce rubidium and cesium.
Uses of Sodium and Potassium The compounds of Na and K (and indeed, of all the alkali metals) have many more uses than the elements themselves [see the Group 1A(1) Family Portrait, p. 573]. Nevertheless, there are some interesting uses of the metals that take advantage of their strong reducing power. Large amounts of Na were used as an alloy with lead to make gasoline antiknock additives, such as tetraethyllead:

$$
4 \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{Cl}(g)+4 \mathrm{Na}(s)+\mathrm{Pb}(s) \longrightarrow\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{4} \mathrm{~Pb}(l)+4 \mathrm{NaCl}(s)
$$

The toxic effects of environmental lead have limited this use to aviation fuel in the United States. Moreover, although leaded gasoline is still used in several developing countries, the global market for tetraethyllead is declining by $15 \%$ annually.

If certain types of nuclear reactors, called breeder reactors (Chapter 24), become a practical way to generate energy in the United States, Na production would increase enormously. Its low melting point, viscosity, and absorption of neutrons, combined with its high thermal conductivity and heat capacity, make it perfect for cooling the reactor and exchanging heat to the steam generator.

The major use of potassium at present is in an alloy with sodium for use as a heat exchanger in chemical and nuclear reactors. Another application relies on production of its superoxide, which it forms by direct contact with $\mathrm{O}_{2}$ :

$$
\mathrm{K}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{KO}_{2}(s)
$$

 miners, divers, submarine crews, and firefighters (see photo):

$$
4 \mathrm{KO}_{2}(s)+4 \mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g) \longrightarrow 4 \mathrm{KHCO}_{3}(s)+3 \mathrm{O}_{2}(g)
$$

## The Indispensable Three: Iron, Copper, and Aluminum

Their familiar presence, innumerable applications, and enormous production levels make three metals-iron (in the form of steel), copper, and aluminum-stand out as indispensable materials of industrial society.
Metallurgy of Iron and Steel Although people have practiced iron smelting for more than 3000 years, it was only a little over 235 years ago that iron assumed its current dominant role. In 1773, an inexpensive process to convert coal to carbon in the form of coke was discovered, and the material was used in a blast furnace. The coke process made iron smelting cheap and efficient and led to large-scale iron production, which ushered in the Industrial Revolution.

Modern society rests, quite literally, on the various alloys of iron known as steel. Although steel production has grown enormously since the $18^{\text {th }}$ centurymore than 700 million tons are produced annually-the process of recovering iron from its ores still employs the same general approach: reduction by carbon in a blast furnace. The most important minerals of iron are listed in Table 22.4. The first four are used for steelmaking, but the sulfide minerals cannot be used because traces of sulfur make the steel brittle.

The conversion of iron ore to iron metal involves a series of overall redox and acid-base reactions that appear quite simple, although the detailed chemistry is not entirely understood even today. A modern blast furnace (Figure 22.16), such as those used in South Korea and Japan, is a tower about 14 m wide by 40 m high, made of a brick that can withstand intense heat. The charge, which consists of an iron ore (usually hematite) containing the mineral, coke, and lime-

stone, is fed through the top. More coke is burned in air at the bottom. The charge falls and meets a blast of rapidly ringquy ail createdby thelnurnangoke

$$
2 \mathrm{C}(s)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}(g)+\text { heat }
$$

At the bottom of the furnace, the temperature exceeds $2000^{\circ} \mathrm{C}$, while at the top, it reaches only $200^{\circ} \mathrm{C}$. As a result, different stages of the overall reaction process occur at different heights as the charge descends:

1. In the upper part of the furnace $\left(200^{\circ} \mathrm{C}\right.$ to $\left.700^{\circ} \mathrm{C}\right)$, the charge is preheated, and a partial reduction step occurs. The hematite is reduced to magnetite and then to iron(II) oxide ( FeO ) by CO , the actual reducing agent for the iron oxides. Carbon dioxide is formed as well. Because the blast of hot air passes through the entire furnace in only 10 s , the various gas-solid reactions do not reach equilibrium, and many intermediate products form. Limestone also decomposes to form $\mathrm{CO}_{2}$ and the basic oxide CaO , which is important later in the process.
2. Lower down, at $700^{\circ} \mathrm{C}$ to $1200^{\circ} \mathrm{C}$, a final reduction step occurs, as some of the coke reduces $\mathrm{CO}_{2}$ to form more CO , which reduces the FeO to Fe .
3. At still higher temperatures, between $1200^{\circ} \mathrm{C}$ and $1500^{\circ} \mathrm{C}$, the iron melts and drips to the bottom of the furnace. Acidic silica particles from the gangue react with basic calcium oxide in a Lewis acid-base reaction to form a molten waste product called slag:

$$
\mathrm{CaO}(s)+\mathrm{SiO}_{2}(s) \longrightarrow \mathrm{CaSiO}_{3}(l)
$$

The siliceous slag drips down and floats on the denser iron (much as Earth's silicate-rich mantle and crust float on its molten iron core).
4. Some unwanted reactions occur at this hottest stage, between $1500^{\circ} \mathrm{C}$ and $2000^{\circ} \mathrm{C}$. Any remaining phosphates and silicates are reduced to P and Si , and some Mn and traces of S dissolve into the molten iron along with carbon. The resulting impure product is called pig iron and contains about $3 \%$ to $4 \% \mathrm{C}$. A small amount of pig iron is used to make cast iron, but most is purified and alloyed to make various kinds of steel.

Figure 22.16 The major reactions in a blast furnace. Iron is produced from iron ore, coke, and limestone in a complex process that depends on the temperature at different heights in the furnace. (A human is shown for scale.)

Animation: Iron Smelting

Was It Slag That Made the Great Ship Go Down? Direct observation of the sunken luxury liner Titanic shows that six small slits caused by collision with an iceberg, rather than an enormous gash, sank the ship. The slits appear between sections of steel plates in the lower hull and suggest weakness in the rivets that connected the plates. Metallurgical analysis of the rivets shows three times as much slag content as modern rivets. Too much of this silicate-rich material makes the wrought iron used in the rivets brittle and easier to break under stress. Moreover, rather than being evenly distributed, the slag particles within the iron, viewed microscopically, appear to be clumped, which causes weak spots. Could lowgrade rivets with too much slag have caused this tragedy? Follow-up analysis of more rivets and a historical search of rivet standards in the early 1900s may finally solve the mystery of what brought down the unsinkable Titanic and caused the deaths of 1500 passengers.

Mining chalcopyrite.

Figure 22.17 The basic-oxygen process for making steel. A, Jets of pure $\mathrm{O}_{2}$ in combination with a basic flux $(\mathrm{CaO})$ are used to remove impurities and lower the carbon content of pig iron in the manufacture of steel. B, Impure molten iron is added to a basic-oxygen furnace.

B

## Apago PDF Enhancer

Pig iron is converted to steel in a separate furnace by means of the basicoxygen process, as shown in Figure 22.17. High-pressure $\mathrm{O}_{2}$ is blown over and through the molten iron, so that impurities ( $\mathrm{C}, \mathrm{Si}, \mathrm{P}, \mathrm{Mn}, \mathrm{S}$ ) are oxidized rapidly. The highly negative standard heats of formation of their oxides (such as $\Delta H_{\mathrm{f}}^{\mathrm{o}}$ of $\mathrm{CO}_{2}=-394 \mathrm{~kJ} / \mathrm{mol}$ and $\Delta H_{\mathrm{f}}^{\mathrm{o}}$ of $\mathrm{SiO}_{2}=-911 \mathrm{~kJ} / \mathrm{mol}$ ) raise the temperature, which speeds the reaction. A lime $(\mathrm{CaO})$ flux is added, which converts the oxides to a molten slag [primarily $\mathrm{CaSiO}_{3}$ and $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ ] that is decanted from the molten steel. The product is carbon steel, which contains $1 \%$ to $1.5 \% \mathrm{C}$ and other impurities. It is alloyed with metals that prevent corrosion and increase its strength or flexibility.

Isolation and Electrorefining of Copper After many centuries of being mined to make bronze and brass articles, copper ores have become less plentiful and less rich in copper, so the metal is more expensive to extract. Despite this, more than 2.5 billion pounds of copper is produced in the United States annually. The most common copper ore is chalcopyrite, $\mathrm{CuFeS}_{2}$, a mixed sulfide of FeS and CuS (see photo). Most remaining deposits contain less than $0.5 \% \mathrm{Cu}$ by mass. To "win" this small amount of copper from the ore requires several metallurgical steps, including a final refining to achieve the $99.99 \%$ purity needed for electrical wiring, copper's most important application.

The low copper content in chalcopyrite must be enriched by removing the iron. The first step in copper extraction is pretreatment by flotation (see Figure 22.11 , p. 994), which concentrates the ore to around $15 \% \mathrm{Cu}$ by mass. The next step in many processing plants is a controlled roasting step, which oxidizes the FeS but not the CuS:

$$
2 \mathrm{FeCuS}_{2}(s)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CuS}(s)+2 \mathrm{FeO}(s)+2 \mathrm{SO}_{2}(g)
$$

To remove the FeO and convert the CuS to a more convenient form, the mixture is heated to $1100^{\circ} \mathrm{C}$ with sand and more of the concentrated ore. Several reactions occur in this step. The FeO reacts with sand to form a molten slag:

$$
\mathrm{FeO}(s)+\mathrm{SiO}_{2}(s) \longrightarrow \mathrm{FeSiO}_{3}(l)
$$

The CuS is thermodynamically unstable at the elevated temperature and decomposes to yield $\mathrm{Cu}_{2} \mathrm{~S}$, which is drawn off as a liquid.

In the final smelting step, the $\mathrm{Cu}_{2} \mathrm{~S}$ is roasted in air, which converts some of it to $\mathrm{Cu}_{2} \mathrm{O}$ :

$$
2 \mathrm{Cu}_{2} \mathrm{~S}(s)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{Cu}_{2} \mathrm{O}(s)+2 \mathrm{SO}_{2}(g)
$$

The two copper(I) compounds then react, with sulfide ion acting as the reducing agent:

$$
\mathrm{Cu}_{2} \mathrm{~S}(s)+2 \mathrm{Cu}_{2} \mathrm{O}(s) \longrightarrow 6 \mathrm{Cu}(l)+\mathrm{SO}_{2}(g)
$$

The copper obtained at this stage is usable for plumbing, but it must be purified further for electrical applications by removing unwanted impurities ( Fe and Ni ) as well as valuable ones $(\mathrm{Ag}, \mathrm{Au}$, and Pt). Purification is accomplished by electrorefining, which involves the oxidation of Cu and the formation of $\mathrm{Cu}^{2+}$ ions in solution, followed by their reduction and the plating out of Cu metal (Figure 22.18). The impure copper obtained from smelting is cast into plates to be used as anodes, and cathodes are made from already purified copper. The electrodes are immersed in acidified $\mathrm{CuSO}_{4}$ solution, and a controlled voltage is applied that accomplishes two tasks simultaneously:

1. Copper and the more active impurities ( $\mathrm{Fe}, \mathrm{Ni}$ ) are oxidized to their cations, while the less active ones $(\mathrm{Ag}, \mathrm{Au}, \mathrm{Pt})$ are not. As the anode slabs react, these unoxidized metals fall off as a valuable "anode mud" and are purified separately. Sale of the precious metals in the anode mud nearly offsets the cost of electricity to operate the cell, makpgacy ©ire Roxpensivenhancer
2. Because Cu is much less active than the Fe and Ni impurities, $\mathrm{Cu}^{2+}$ ions are reduced at the cathode, but $\mathrm{Fe}^{2+}$ and $\mathrm{Ni}^{2+}$ ions remain in solution:

$$
\begin{array}{ll}
\mathrm{Cu}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cu}(s) & E^{\circ}=0.34 \mathrm{~V} \\
\mathrm{Ni}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Ni}(s) & E^{\circ}=-0.25 \mathrm{~V} \\
\mathrm{Fe}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Fe}(s) & E^{\circ}=-0.44 \mathrm{~V}
\end{array}
$$

Figure 22.18 The electrorefining of copper. A, Copper is refined electrolytically, using impure slabs of copper as anodes and sheets of pure copper as cathodes. The $\mathrm{Cu}^{2+}$ ions released from the anode are reduced to Cu metal and plate out at the cathode. The "anode mud" contains valuable metal byproducts. B, A small section of an industrial facility for electrorefining copper.

Mining bauxite.

Isolation, Uses, and Recycling of Aluminum Aluminum is the most abundant metal in Earth's crust by mass and the third most abundant element (after O and Si). It is found in numerous aluminosilicate minerals (Gallery, pp. 592-594), such as feldspars, micas, and clays, and in the rare gems garnet, beryl, spinel, and turquoise. Corundum, pure aluminum oxide $\left(\mathrm{Al}_{2} \mathrm{O}_{3}\right)$, is extremely hard; mixed with traces of transition metals, it exists as ruby and sapphire. Impure $\mathrm{Al}_{2} \mathrm{O}_{3}$ is used in sandpaper and other abrasives.

Through eons of weathering, certain clays became bauxite, the major ore of aluminum. This mixed oxide-hydroxide occurs in enormous surface deposits in Mediterranean and tropical regions (see photo), but with world aluminum production approaching 100 million tons annually, it may someday be scarce. In addition to hydrated $\mathrm{Al}_{2} \mathrm{O}_{3}$ (about $75 \%$ ), industrial-grade bauxite also contains $\mathrm{Fe}_{2} \mathrm{O}_{3}$, $\mathrm{SiO}_{2}$, and $\mathrm{TiO}_{2}$, which are removed during the extraction.

The overall two-step process combines hydro- and electrometallurgical techniques. In the first step, $\mathrm{Al}_{2} \mathrm{O}_{3}$ is separated from bauxite; in the second, it is converted to the metal.

1. Isolating $\mathrm{Al}_{2} \mathrm{O}_{3}$ from bauxite. After mining, bauxite is pretreated by extended boiling in $30 \% \mathrm{NaOH}$ in the Bayer process, which involves acid-base, solubility, and complex-ion equilibria. The acidic $\mathrm{SiO}_{2}$ and the amphoteric $\mathrm{Al}_{2} \mathrm{O}_{3}$ dissolve in the base, but the basic $\mathrm{Fe}_{2} \mathrm{O}_{3}$ and $\mathrm{TiO}_{2}$ do not:

$$
\begin{aligned}
\mathrm{SiO}_{2}(s)+2 \mathrm{NaOH}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow \mathrm{Na}_{2} \mathrm{Si}(\mathrm{OH})_{6}(a q) \\
\mathrm{Al}_{2} \mathrm{O}_{3}(s)+2 \mathrm{NaOH}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow 2 \mathrm{NaAl}(\mathrm{OH})_{4}(a q) \\
\mathrm{Fe}_{2} \mathrm{O}_{3}(s)+\mathrm{NaOH}(a q) & \longrightarrow \text { no reaction } \\
\mathrm{TiO}_{2}(s)+\mathrm{NaOH}(a q) & \longrightarrow \text { no reaction }
\end{aligned}
$$

Further heating slowly precipitates the $\mathrm{Na}_{2} \mathrm{Si}(\mathrm{OH})_{6}$ as an aluminosilicate, which is filtered out with the insoluble $\mathrm{Fe}_{2} \mathrm{O}_{3}$ and $\mathrm{TiO}_{2}$ ("red mud").
 sion of complex-ion equilibria that the aluminate ion, $\mathrm{Al}(\mathrm{OH})_{4}{ }^{-}(a q)$, is actually the complex ion $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}(\mathrm{OH})_{4}{ }^{-}$, in which four of the six water molecules surrounding $\mathrm{Al}^{3+}$ have each lost a proton (see Figure 19.16, p. 869). Weakly acidic $\mathrm{CO}_{2}$ is added to produce a small amount of $\mathrm{H}^{+}$ion, which reacts with this complex ion. Cooling supersaturates the solution, and the solid that forms is filtered out:

$$
\begin{aligned}
\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{HCO}_{3}^{-}(a q) \\
\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}(\mathrm{OH})_{4}^{-}(a q)+\mathrm{H}^{+}(a q) & \longmapsto \mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}(\mathrm{OH})_{3}(s)
\end{aligned}
$$

[Recall that we usually write $\mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}(\mathrm{OH})_{3}$ more simply as $\mathrm{Al}(\mathrm{OH})_{3}$.]
Drying at high temperature converts the hydroxide to the oxide:

$$
2 \mathrm{Al}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}(\mathrm{OH})_{3}(s) \xrightarrow{\Delta} \mathrm{Al}_{2} \mathrm{O}_{3}(s)+9 \mathrm{H}_{2} \mathrm{O}(g)
$$

2. Converting $\mathrm{Al}_{2} \mathrm{O}_{3}$ to the free metal. Aluminum is an active metal, much too strong a reducing agent to be formed at the cathode from aqueous solution (Section 21.7), so the oxide itself must be electrolyzed. However, the melting point of $\mathrm{Al}_{2} \mathrm{O}_{3}$ is very high $\left(2030^{\circ} \mathrm{C}\right)$, so it is dissolved in molten cryolite $\left(\mathrm{Na}_{3} \mathrm{AlF}_{6}\right)$ to give a mixture that is electrolyzed at $\sim 1000^{\circ} \mathrm{C}$. Obviously, the use of cryolite provides a major energy (and cost) savings. The only sizeable cryolite mines are in Greenland, however, and they cannot supply enough natural mineral to meet the demand. Therefore, production of synthetic cryolite has become a major subsidiary industry in aluminum manufacture.

The electrolytic step, called the Hall-Heroult process, takes place in a graphite-lined furnace, with the lining itself acting as the cathode. Anodes of graphite dip into the molten $\mathrm{Al}_{2} \mathrm{O}_{3}-\mathrm{Na}_{3} \mathrm{AlF}_{6}$ mixture (Figure 22.19). The cell typically operates at a moderate voltage of 4.5 V , but with an enormous current flow of $1.0 \times 10^{5}$ to $2.5 \times 10^{5} \mathrm{~A}$.

The process is complex and its details are still not entirely known. Therefore, the specific reactions shown below are chosen from among several other possibilities. Molten cryolite contains several ions (including $\mathrm{AlF}_{6}{ }^{3-}, \mathrm{AlF}_{4}{ }^{-}$, and $\mathrm{F}^{-}$), which react with $\mathrm{Al}_{2} \mathrm{O}_{3}$ to form fluoro-oxy ions (including $\mathrm{AlOF}_{3}{ }^{2-}, \mathrm{Al}_{2} \mathrm{OF}_{6}{ }^{2-}$, and $\mathrm{Al}_{2} \mathrm{O}_{2} \mathrm{~F}_{4}{ }^{2-}$ ) that dissolve in the mixture. For example,

$$
2 \mathrm{Al}_{2} \mathrm{O}_{3}(s)+2 \mathrm{AlF}_{6}{ }^{3-}(l) \longrightarrow 3 \mathrm{Al}_{2} \mathrm{O}_{2} \mathrm{~F}_{4}{ }^{2-}(l)
$$

Al forms at the cathode (reduction), shown here with $\mathrm{AlF}_{6}{ }^{3-}$ as reactant:

$$
\mathrm{AlF}_{6}{ }^{3-}(l)+3 \mathrm{e}^{-} \longrightarrow \mathrm{Al}(l)+6 \mathrm{~F}^{-}(l) \quad[\text { cathode; reduction] }
$$

The graphite anodes are oxidized and form carbon dioxide gas. Using one of the fluoro-oxy species as an example, the anode reaction is
$\mathrm{Al}_{2} \mathrm{O}_{2} \mathrm{~F}_{4}{ }^{2-}(l)+8 \mathrm{~F}^{-}(l)+\mathrm{C}($ graphite $) \longrightarrow 2 \mathrm{AlF}_{6}{ }^{3-}(l)+\mathrm{CO}_{2}(g)+4 \mathrm{e}^{-}$
[anode; oxidation]
Thus, the anodes themselves are consumed in this half-reaction and must be replaced frequently.

Combining the three previous equations and making sure that $\mathrm{e}^{-}$gained at the cathode equal $\mathrm{e}^{-}$lost at the anode gives the overall reaction:
 The Hall-Heroult process uses an enormous quantity of energy: aluminum production accounts for more than $5 \%$ of total U.S. electrical usage.

Aluminum is a superb decorative, functional, and structural metal. It is lightweight, attractive, easy to work, and forms strong alloys. Although Al is very active, it does not corrode readily because of an adherent oxide layer that forms rapidly in air and prevents more $\mathrm{O}_{2}$ from penetrating. Nevertheless, when it is in

Energy Received and Returned Aluminum manufacture in the United States uses more electricity in 1 day than a city of 100,000 uses in 1 year! The reason for the high energy needs of Al manufacture is the electron configuration of Al ([Ne] $3 s^{2} 3 p^{1}$ ). Each $\mathrm{Al}^{3+}$ ion needs $3 \mathrm{e}^{-}$to form an Al atom, and the atomic mass of Al is so low $(\sim 27 \mathrm{~g} / \mathrm{mol})$ that 1 mol of $\mathrm{e}^{-}$ produces only 9 g of Al. Compare this with the masses of Mg or Ca (two other lightweight structural metals) that 1 mol of $\mathrm{e}^{-}$produces:

$$
\begin{aligned}
\frac{1}{3} \mathrm{Al}^{3+}+\mathrm{e}^{-} & =\frac{1}{3} \mathrm{Al}(s), \sim 9 \mathrm{~g} \\
\frac{1}{2} \mathrm{Mg}^{2+}+\mathrm{e}^{-} & =\frac{1}{2} \mathrm{Mg}(s), \sim 12 \mathrm{~g} \\
\frac{1}{2} \mathrm{Ca}^{2+}+\mathrm{e}^{-} & =\frac{1}{2} \mathrm{Ca}(s), \sim 20 \mathrm{~g}
\end{aligned}
$$

An Al battery can turn this disadvantage around. Once produced, Al represents a concentrated form of electrical energy that can deliver 1 mol of $\mathrm{e}^{-}(96,500 \mathrm{C})$ for every 9 g of Al consumed in the battery. Thus, its electrical output per gram of metal is high. In fact, aluminum-air batteries are now being produced.

Figure 22.19 The electrolytic cell in the manufacture of aluminum. Purified $\mathrm{Al}_{2} \mathrm{O}_{3}$ is mixed with cryolite $\left(\mathrm{Na}_{3} \mathrm{AlF}_{6}\right)$ and melted. Reduction at the graphite furnace lining (cathode) gives molten Al . Oxidation at the graphite rods (anodes) slowly converts them to $\mathrm{CO}_{2}$, so they must be replaced periodically.

Figure 22.20 The many familiar and essential uses of aluminum.

contact with less active metals such as $\mathrm{Fe}, \mathrm{Cu}$, and Pb , aluminum becomes the anode and deteriorates rapidly (Section 21.6). To prevent this, aluminum objects are often anodized, that is, made to act as the anode in an electrolysis that coats them with an oxide layer. The object is immersed in a $20 \% \mathrm{H}_{2} \mathrm{SO}_{4}$ bath and connected to a graphite cathode:

$$
\begin{aligned}
6 \mathrm{H}^{+}(a q)+6 \mathrm{e}^{-} & \longrightarrow 3 \mathrm{H}_{2}(g) \\
2 \mathrm{Al}(s)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Al}_{2} \mathrm{O}_{3}(s)+6 \mathrm{H}^{+}(a q)+6 \mathrm{e}^{-} & \text {[cathode; reduction] } \\
\hline 2 \mathrm{Al}(s)+3 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Al}_{2} \mathrm{O}_{3}(s)+3 \mathrm{H}_{2}(g) & \text { [overerall (cexidation] reaction] }
\end{aligned}
$$

 the object's intended use. Figure 22.20 is a pie chart showing the countless uses of aluminum.

More than 3.5 billion pounds ( 1.5 million metric tons) of aluminum cans and packaging are discarded each year-a waste of one of the most useful materials in the world and the energy used to make it. A quick calculation of the energy needed to prepare 1 mol of Al from purified $\mathrm{Al}_{2} \mathrm{O}_{3}$, compared with the energy needed for recycling, conveys a clear message. The overall cell reaction in the Hall-Heroult process has a $\Delta H^{\circ}$ of 2272 kJ and a $\Delta S^{\circ}$ of $635.4 \mathrm{~J} / \mathrm{K}$. If we consider only the standard free energy change of the reaction at $1000 .{ }^{\circ} \mathrm{C}$, for 1 mol of Al , we obtain

$$
\Delta G^{\circ}=\Delta H^{\circ}-T \Delta S^{\circ}=\frac{2272 \mathrm{~kJ}}{4 \mathrm{~mol} \mathrm{Al}}-\left(1273 \mathrm{~K} \times \frac{0.6354 \mathrm{~kJ} / \mathrm{K}}{4 \mathrm{~mol} \mathrm{Al}}\right)=365.8 \mathrm{~kJ} / \mathrm{mol} \mathrm{Al}
$$

The molar mass of Al is nearly twice the mass of a soft-drink or beer can, so the electrolysis step requires nearly 200 kJ of energy for each can!

When aluminum is recycled, the major energy input (which is for melting the cans and foil) has been calculated as $\sim 26 \mathrm{~kJ} / \mathrm{mol}$ Al. The ratio of these energy inputs is

$$
\frac{\text { Energy to recycle } 1 \mathrm{~mol} \mathrm{Al}}{\text { Energy for electrolysis of } 1 \mathrm{~mol} \mathrm{Al}}=\frac{26 \mathrm{~kJ}}{365.8 \mathrm{~kJ}}=0.071
$$

Based on just these portions of the process, recycling uses about $7 \%$ as much energy as electrolysis. Recent energy estimates for the entire manufacturing process (including mining, pretreating, maintaining operating conditions, electrolyzing, and so forth) are about $6000 \mathrm{~kJ} / \mathrm{mol} \mathrm{Al}$, which means recycling requires less than $1 \%$ as much energy as manufacturing! The economic advantages, not to mention the environmental ones, are obvious, and recycling of aluminum has become common in the United States (see photo).

## Mining the Sea: Magnesium and Bromine

In the not too distant future, as terrestrial sources of certain elements become scarce or too costly to mine, the oceans will become an important source. Despite the abundant distribution of magnesium on land, it is already being obtained from the sea, and its ocean-based production is a good example of the approach we might one day use for other elements. Bromine, too, is recovered from the sea as well as from inland brines.

Isolation and Uses of Magnesium The Dow process for the isolation of magnesium from the sea involves steps that are similar to the procedures used for rocky ores (Figure 22.21):

1. Mining. Intake of seawater and straining the debris are the "mining" steps. No pretreatment is needed.
2. Converting to mineral. The dissolved $\mathrm{Mg}^{2+}$ ion is converted to the mineral $\mathrm{Mg}(\mathrm{OH})_{2}$ with $\mathrm{Ca}(\mathrm{OH})_{2}$, which is generated on-site (at the plant). Seashells $\left(\mathrm{CaCO}_{3}\right)$ are crushed, decomposed with heat to CaO , and mixed with water to make slaked lime $\left[\mathrm{Ca}(\mathrm{OH})_{2}\right]$. This is pumped into the seawater intake tank to precipitate the dissolved $\mathrm{Mg}^{2+}$ as the hydroxide ( $K_{\mathrm{sp}} \approx 10^{-9}$ ):

$$
\mathrm{Ca}(\mathrm{OH})_{2}(a q)+\mathrm{Mg}^{2+}(a q) \longrightarrow \mathrm{Mg}(\mathrm{OH})_{2}(s)+\mathrm{Ca}^{2+}(a q)
$$

3. Converting to compound. The solid $\mathrm{Mg}(\mathrm{OH})_{2}$ is filtered and mixed with excess HCl , which is also made on-site, to form aqueous $\mathrm{MgCl}_{2}$ :

$$
\mathrm{Mg}(\mathrm{OH})_{2}(s)+2 \mathrm{HCl}(a q) \longrightarrow \mathrm{MgCl}_{2}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

The water is evaporated in stages to give solid, hydrated $\mathrm{MgCl}_{2} \cdot n \mathrm{H}_{2} \mathrm{O}$.
4. Electrochemical redox. Heating above $700^{\circ} \mathrm{C}$ drives off the water of hydration and melts the $\mathrm{MgCl}_{2}$. Electrolysis gives chlorine gas and the molten metal, which floats on the denser moltensatigo PDF Enhancer

$$
\mathrm{MgCl}_{2}(l) \xrightarrow{\mathrm{Mg}(l)+\mathrm{Cl}_{2}(g)}
$$

The $\mathrm{Cl}_{2}$ that forms is recycled to make the HCl used in step 3.

Figure 22.21 The production of elemental Mg from seawater. The Dow process involves obtaining $\mathrm{Mg}^{2+}$ ion from seawater; the $\mathrm{Mg}^{2+}$ is converted to $\mathrm{Mg}(\mathrm{OH})_{2}$ and then to aqueous $\mathrm{MgCl}_{2}$, which is evaporated to dryness and then electrolytically reduced to Mg metal and $\mathrm{Cl}_{2}$ gas.

Jet engine assembly.

Magnesium is the lightest structural metal available (about one-half the density of Al and one-fifth that of steel). Although Mg is quite reactive, it forms an extremely adherent, high-melting oxide layer ( MgO ); thus, it finds many uses in metal alloys and can be machined into any form. Magnesium alloys occur in everything from aircraft bodies to camera bodies, and from luggage to auto engine blocks. The pure metal is a strong reducing agent, which makes it useful for sacrificial anodes (Section 21.6) and in the metallurgical extraction of other metals, such as $\mathrm{Be}, \mathrm{Ti}, \mathrm{Zr}, \mathrm{Hf}$, and U. For example, titanium, an essential component of jet engines (see photo), is made from its major ore, ilmenite, in two steps:
(1) $2 \mathrm{FeTiO}_{3}(s)+7 \mathrm{Cl}_{2}(g)+6 \mathrm{C}(s) \longrightarrow 2 \mathrm{TiCl}_{4}(l)+2 \mathrm{FeCl}_{3}(s)+6 \mathrm{CO}(g)$

$$
\begin{equation*}
\mathrm{TiCl}_{4}(l)+2 \mathrm{Mg}(l) \longrightarrow \mathrm{Ti}(s)+2 \mathrm{MgCl}_{2}(l) \tag{2}
\end{equation*}
$$

Isolation and Uses of Bromine The largest source of bromine is the oceans, where it occurs as $\mathrm{Br}^{-}$at a concentration of $0.065 \mathrm{~g} / \mathrm{L}(65 \mathrm{ppm})$. However, the cost of concentrating such a dilute solution shifts the choice of source, when available, to much more concentrated salt lakes and natural brines. Arkansas brines, the most important source in the United States, contain about $4.5 \mathrm{~g} \mathrm{Br}^{-} / \mathrm{L}$ ( 4500 ppm ). At standard-state conditions, the $\mathrm{Br}^{-}$is readily oxidized to $\mathrm{Br}_{2}$ with aqueous $\mathrm{Cl}_{2}$ :

$$
2 \mathrm{Br}^{-}(a q)+\mathrm{Cl}_{2}(a q) \longrightarrow \mathrm{Br}_{2}(l)+2 \mathrm{Cl}^{-}(a q) \quad \Delta G^{\circ}=-61.5 \mathrm{~kJ}
$$

The $\mathrm{Br}_{2}$ is removed by passing steam through the mixture and then cooling and drying the liquid bromine. Iodide is present in these brines also, and it is oxidized to $\mathrm{I}_{2}$ by aqueous $\mathrm{Cl}_{2}$ in a similar way.

World production of $\mathrm{Br}_{2}$ is about $1 \%$ that of $\mathrm{Cl}_{2}$. Its major use is in the preparation of organic chemicals, such as ethylene dibromide, which was added to leaded gasoline to prevent lead oxides from forming and depositing on engine parts. Newer products requiring bromine include the flame retardants in rugs and textiles Brominesis atso needed in the synthesis of inorganic chemicals, especially silver bromide for photographic emulsions.

## The Many Sources and Uses of Hydrogen

Although hydrogen accounts for $90 \%$ of the atoms in the universe, it makes up only $15 \%$ of the atoms in Earth's crust. Moreover, whereas it occurs in the universe mostly as $\mathrm{H}_{2}$ molecules and free H atoms, virtually all hydrogen in the crust is combined with other elements, either oxygen in natural waters or carbon in biomass, petroleum, and coal.
Properties of the Hydrogen Isotopes Hydrogen has three naturally occurring isotopes. Ordinary hydrogen $\left({ }^{1} \mathrm{H}\right)$, or protium, is the most abundant and has no neutrons. Deuterium ( ${ }^{2} \mathrm{H}$ or D$)$, the next in abundance, has one neutron, and rare, radioactive tritium ( ${ }^{3} \mathrm{H}$ or T$)$ has two. All three occur as diatomic molecules, $\mathrm{H}_{2}$, $\mathrm{D}_{2}\left(\right.$ or $\left.{ }^{2} \mathrm{H}_{2}\right)$, and $\mathrm{T}_{2}\left(\right.$ or $\left.{ }^{3} \mathrm{H}_{2}\right)$, as well as HD, DT, and HT. Table 22.5 compares

## Table 22.5 Some Molecular and Physical Properties of Diatomic Protium, Deuterium, and Tritium

| Property | $\mathbf{H}_{\mathbf{2}}$ | $\mathbf{D}_{\mathbf{2}}$ | $\mathbf{T}_{\mathbf{2}}$ |
| :--- | :---: | :---: | :---: |
| Molar mass $(\mathrm{g} / \mathrm{mol})$ | 2.016 | 4.028 | 6.032 |
| Bond length $(\mathrm{pm})$ | 74.14 | 74.14 | 74.14 |
| Melting point $(\mathrm{K})$ | 13.96 | 18.73 | 20.62 |
| Boiling point $(\mathrm{K})$ | 20.39 | 23.67 | 25.04 |
| $\Delta H_{\text {fus }}^{\circ}(\mathrm{kJ} / \mathrm{mol})$ | 0.117 | 0.197 | 0.250 |
| $\Delta H_{\text {vap }}^{\circ}(\mathrm{kJ} / \mathrm{mol})$ | 0.904 | 1.226 | 1.393 |
| Bond energy $(\mathrm{kJ} / \mathrm{mol}$ | 432 | 443 | 447 |
| $\quad$ at 298 K$)$ |  |  |  |

some molecular and physical properties of $\mathrm{H}_{2}, \mathrm{D}_{2}$, and $\mathrm{T}_{2}$. As you can see, the heavier the isotope is, the higher the molar mass of the molecule, and the higher its melting point, boiling point, and heats of phase change; it also effuses at a lower rate (Section 5.6).

Because hydrogen is so light, the relative difference in mass of its isotopes is enormous compared to that of isotopes of other common elements. (For example, the mass of ${ }^{13} \mathrm{C}$ is only $8 \%$ greater than that of ${ }^{12} \mathrm{C}$.) Note, especially, that the mass difference leads to different bond energies, which affect reactivity. Because the mass of D is twice the mass of $\mathrm{H}, \mathrm{H}$ atoms bonded to a given atom vibrate at a higher frequency than do D atoms, so their bonds are higher in energy. As a result, the bond to $H$ is weaker and thus quicker to break. Therefore, any reaction that includes breaking a bond to hydrogen in the rate-determining step occurs faster with $H$ than with $D$. This phenomenon is called a kinetic isotope effect; we'll see an example shortly. No other element displays a kinetic isotope effect nearly as large.

Industrial Production of Hydrogen Hydrogen gas $\left(\mathrm{H}_{2}\right)$ is produced on an industrial scale worldwide: 250,000 metric tons $\left(3 \times 10^{12} \mathrm{~L}\right.$ at STP; equivalent to $\left.\sim 1 \times 10^{11} \mathrm{~mol}\right)$ are produced annually in the United States alone. All production methods are energy intensive, so the choice is determined by energy costs. In Scandinavia, where hydroelectric power is plentiful, electrolysis is the chosen method; on the other hand, where natural gas from oil refineries is plentiful, as in the United States and Great Britain, thermal methods are used to produce hydrogen.

The most common thermal methods use water and a simple hydrocarbon in two steps. Modern U.S. plants use methane, which has the highest H/C ratio of any hydrocarbon. In the first step, the reactants are heated to around $1000^{\circ} \mathrm{C}$ over a nickel-based catalyst in the endonquatgem-Ryphing precesancer

$$
\mathrm{CH}_{4}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \longrightarrow \mathrm{CO}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \quad \Delta H^{\circ}=206 \mathrm{~kJ}
$$

Heat is supplied by burning methane at the refinery. To generate more $\mathrm{H}_{2}$, the product mixture (called water gas) is heated with steam at $400^{\circ} \mathrm{C}$ over an iron or cobalt oxide catalyst in the exothermic water-gas shift reaction, and the CO reacts:

$$
\mathrm{H}_{2} \mathrm{O}(g)+\mathrm{CO}(g) \rightleftharpoons \mathrm{CO}_{2}(g)+\mathrm{H}_{2}(g) \quad \Delta H^{\circ}=-41 \mathrm{~kJ}
$$

The reaction mixture is recycled several times, which decreases the CO to around $0.2 \%$ by volume. Passing the mixture through liquid water removes the more soluble $\mathrm{CO}_{2}$ (solubility $=0.034 \mathrm{~mol} / \mathrm{L}$ ) from the $\mathrm{H}_{2}$ (solubility $<0.001 \mathrm{~mol} / \mathrm{L}$ ). Calcium oxide can also be used to remove $\mathrm{CO}_{2}$ by formation of $\mathrm{CaCO}_{3}$. By removing $\mathrm{CO}_{2}$, these steps shift the equilibrium position to the right and produce $\mathrm{H}_{2}$ that is about $98 \%$ pure. To attain greater purity ( $\sim 99.9 \%$ ), the gas mixture is passed through a synthetic zeolite (see the Gallery, p. 593) selected to filter out nearly all molecules larger than $\mathrm{H}_{2}$.

In regions where inexpensive electricity is available, very pure $\mathrm{H}_{2}$ is prepared through electrolysis of water with $\mathrm{Pt}($ or Ni ) electrodes:

$$
\begin{array}{cll}
2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(g)+2 \mathrm{OH}^{-}(a q) & E=-0.42 \mathrm{~V} & \text { [cathode; reduction] } \\
\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \frac{1}{2} \mathrm{O}_{2}(g)+2 \mathrm{H}^{+}(a q)+2 \mathrm{e}^{-} & E=0.82 \mathrm{~V} & \text { [anode; oxidation] } \\
\hline \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(g) & E_{\text {cell }}=-0.42 \mathrm{~V}-0.82 \mathrm{~V}=-1.24 \mathrm{~V}
\end{array}
$$

Overvoltage makes the cell potential about -2 V (Section 21.7). Therefore, under typical operating conditions, it takes about 400 kJ of energy to produce 1 mol of $\mathrm{H}_{2}$ :

$$
\Delta G=-n F E=\left(-2 \mathrm{~mol} \mathrm{e}^{-}\right)\left(\frac{96.5 \mathrm{~kJ}}{\mathrm{~V} \cdot \mathrm{~mol} \mathrm{e}^{-}}\right)(-2 \mathrm{~V})=4 \times 10^{2} \mathrm{~kJ} / \mathrm{mol} \mathrm{H}_{2}
$$

High-purity $\mathrm{O}_{2}$ is a valuable byproduct of this process that offsets some of the costs of isolating $\mathrm{H}_{2}$.

Calcium reacts with water to form $\mathrm{H}_{2}$.

Laboratory Production of Hydrogen You may already have produced small amounts of $\mathrm{H}_{2}$ in the lab by one of several methods. A characteristic reaction of the very active metals in Groups $1 \mathrm{~A}(1)$ and $2 \mathrm{~A}(2)$ is the reduction of water to $\mathrm{H}_{2}$ and $\mathrm{OH}^{-}$(see photo):

$$
\mathrm{Ca}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ca}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)+\mathrm{H}_{2}(g)
$$

Alternatively, the strongly reducing hydride ion can be used:

$$
\mathrm{NaH}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Na}^{+}(a q)+\mathrm{OH}^{-}(a q)+\mathrm{H}_{2}(g)
$$

Less active metals reduce $\mathrm{H}^{+}$in acids:

$$
\mathrm{Zn}(s)+2 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{H}_{2}(g)
$$

In view of hydrogen's great potential as a fuel, chemists are seeking ways to decompose water by lowering the overall activation energy of the process. More than 10,000 thermodynamically and kinetically favorable water-splitting schemes have been devised.

However, at $298 \mathrm{~K}, \Delta G^{\circ}$ for the decomposition of 1 mol of $\mathrm{H}_{2} \mathrm{O}(g)$ is 229 kJ , so all water-splitting schemes require energy. Given the increase in the number of moles of gas, $\Delta S^{\circ}$ is positive; therefore, this is an endothermic process $\left(\Delta H^{\circ}>0\right)$ and, at standard-state conditions, requires heat to occur spontaneously. One promising source of this heat is focused sunlight.

Industrial Uses of Hydrogen Typically, a plant produces $\mathrm{H}_{2}$ to make some other end product. In fact, more than $95 \%$ of $\mathrm{H}_{2}$ produced industrially is consumed onsite in ammonia or petrochemical facilities. In a plant that synthesizes $\mathrm{NH}_{3}$ from $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$, the reactant gases are formed through a series of reactions that involve methane, including the steam-reforming and water-gas shift reactions discussed previously. For this reason, the cost of $\mathrm{NH}_{3}$ is closely correlated with that of $\mathrm{CH}_{4}$.
ABeregsa typarexamplefanche ieaction series in an ammonia plant works. The steam-reforming reaction is performed with excess $\mathrm{CH}_{4}$, which depletes the reaction mixture of $\mathrm{H}_{2} \mathrm{O}$ :

$$
\mathrm{CH}_{4}(g ; \text { excess })+\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow \mathrm{CO}(g)+3 \mathrm{H}_{2}(g)
$$

In the next step, an excess of the product mixture $\left(\mathrm{CH}_{4}, \mathrm{CO}\right.$, and $\left.\mathrm{H}_{2}\right)$ is burned in an amount of air $\left(\mathrm{N}_{2}+\mathrm{O}_{2}\right)$ that is insufficient to effect complete combustion, but is just enough to consume the $\mathrm{O}_{2}$, heat the mixture to $1100^{\circ} \mathrm{C}$, and form additional $\mathrm{H}_{2} \mathrm{O}$ :

$$
\begin{aligned}
4 \mathrm{CH}_{4}(g ; \text { excess })+7 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)+2 \mathrm{CO}(g)+8 \mathrm{H}_{2} \mathrm{O}(g) \\
2 \mathrm{H}_{2}(g ; \text { excess })+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(g) \\
2 \mathrm{CO}(g ; \text { excess })+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)
\end{aligned}
$$

Any remaining $\mathrm{CH}_{4}$ reacts by the steam-reforming reaction, the remaining CO reacts by the water-gas shift reaction $\left(\mathrm{H}_{2} \mathrm{O}+\mathrm{CO} \rightleftharpoons \mathrm{CO}_{2}+\mathrm{H}_{2}\right)$ to form more $\mathrm{H}_{2}$, and then the $\mathrm{CO}_{2}$ is removed with CaO . The amounts are carefully adjusted to produce a final mixture that contains a $1 / 3$ ratio of $\mathrm{N}_{2}$ (from the added air) to $\mathrm{H}_{2}$ (with traces of $\mathrm{CH}_{4}$, Ar, and CO). This mixture is used directly in the synthesis of ammonia, described in Chapter 17 (see the Chemical Connections essay, pp. 771-772).

A second major use of $\mathrm{H}_{2}$ is in hydrogenation of the $\mathrm{C}=\mathrm{C}$ bonds in liquid oils to form the $\mathrm{C}-\mathrm{C}$ bonds in solid fats and margarine. The process uses $\mathrm{H}_{2}$ in contact with transition metal catalysts, such as powdered nickel (see Figure 16.24, p. 722). Solid fats are also used in commercial baked goods. Look at the list of ingredients on most packages of bread, cake, and cookies, and you'll see the "partially hydrogenated vegetable oils" made by this process.

Hydrogen is also essential in the manufacture of numerous "bulk" chemicals, those that are produced in large amounts because they have many further uses. One application that has been gaining great attention is the production
of methanol. In this process, carbon monoxide reacts with hydrogen over a copper-zinc oxide catalyst:

$$
\mathrm{CO}(g)+2 \mathrm{H}_{2}(g) \xrightarrow{\text { Cu-ZnO catalyst }} \mathrm{CH}_{3} \mathrm{OH}(l)
$$

Many automotive engineers expect methanol to be used as a gasoline additive.
Of course, as less expensive sources of hydrogen become available, it will be used directly in fuel cells on a major scale (Section 21.5).
Production and Uses of Deuterium Deuterium and its compounds are produced from $\mathrm{D}_{2} \mathrm{O}$ (heavy water), which is present as a minor component ( $0.016 \mathrm{~mol} \%$ $\mathrm{D}_{2} \mathrm{O}$ ) in normal water and is isolated on the multiton scale by electrolytic enrichment. This process is based on the kinetic isotope effect for hydrogen noted earlier, specifically on the higher rate of bond breaking for $O-H$ bonds compared to $O-D$ bonds, and thus on the higher rate of electrolysis of $\mathrm{H}_{2} \mathrm{O}$ compared with $\mathrm{D}_{2} \mathrm{O}$.

For example, with Pt electrodes, $\mathrm{H}_{2} \mathrm{O}$ is electrolyzed about 14 times faster than $\mathrm{D}_{2} \mathrm{O}$. As some of the liquid decomposes to the elemental gases, the remainder becomes enriched in $\mathrm{D}_{2} \mathrm{O}$. Thus, by the time the volume of water has been reduced to $1 / 20,000$ of its original volume, the remaining water is around $99 \%$ $\mathrm{D}_{2} \mathrm{O}$. By combining samples and repeating the electrolysis, more than $99.9 \% \mathrm{D}_{2} \mathrm{O}$ is obtained.

Deuterium gas is produced by electrolysis of $\mathrm{D}_{2} \mathrm{O}$ or by any of the chemical reactions that produce hydrogen gas from water, such as

$$
2 \mathrm{Na}(s)+2 \mathrm{D}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{Na}^{+}(a q)+2 \mathrm{OD}^{-}(a q)+\mathrm{D}_{2}(g)
$$

Compounds containing deuterium (or tritium) are produced from reactions that give rise to the corresponding hydrogen-containing compound; for example,

$$
\mathrm{SiCl}_{4}(l)+2 \mathrm{D}_{2} \mathrm{O}(l) \longrightarrow \mathrm{SiO}_{2}(s)+4 \mathrm{DCl}(g)
$$

Compounds with acidic protons undegohydrogemdentriuntexthange. CeI

$$
\mathrm{CH}_{3} \mathrm{COOH}(l)+\mathrm{D}_{2} \mathrm{O}(l ; \text { excess }) \longrightarrow \mathrm{CH}_{3} \mathrm{COOD}(l)+\mathrm{DHO}(l ; \text { small amount })
$$

Notice that only the acidic H atom, the one in the COOH group, is exchanged, not any of those attached to carbon. We discuss the natural and synthetic formation of tritium in Chapter 24.

## Section Summary

Production highlights of key elements are as follows:

- Na is isolated by electrolysis of molten NaCl in the Downs process; $\mathrm{Cl}_{2}$ is a byproduct.
- K is produced by reduction with Na in a thermal process.
- Fe is produced through a multistep high-temperature process in a blast furnace. The crude pig iron is converted to carbon steel in the basic-oxygen process and then alloyed with other metals to make different steels.
- Cu is produced by concentration of the ore through flotation, reduction to the metal by smelting, and purification by electrorefining. The metal has extensive electrical and plumbing uses.
- Al is extracted from bauxite by pretreating the ore with concentrated base, followed by electrolysis of the $\mathrm{Al}_{2} \mathrm{O}_{3}$ in molten cryolite. Al alloys are widely used in homes and industry. The total energy required to extract Al from its ore is over 100 times that needed for recycling it.
- The $\mathrm{Mg}^{2+}$ in seawater is converted to $\mathrm{Mg}(\mathrm{OH})_{2}$ and then to $\mathrm{MgCl}_{2}$, which is electrolyzed to obtain the metal; Mg forms strong, lightweight alloys.
- $\mathrm{Br}_{2}$ is obtained from brines by oxidizing $\mathrm{Br}^{-}$with $\mathrm{Cl}_{2}$.
- $\mathrm{H}_{2}$ is produced by electrolysis of water or in the formation of gaseous fuels from hydrocarbons. It is used in $\mathrm{NH}_{3}$ production and in hydrogenation of vegetable oils. The isotopes of hydrogen differ significantly in atomic mass and thus in the rate at which their bonds to other atoms break. This difference is used to obtain $\mathrm{D}_{2} \mathrm{O}$ from water.

### 22.5 CHEMICAL MANUFACTURING: TWO CASE STUDIES

From laboratory-scale endeavors of the first half of the $19^{\text {th }}$ century, today's chemical industries have grown to multinational corporations producing materials that define modern life: polymers, electronics, pharmaceuticals, consumer goods, and fuels. In this final section, we examine the interplay of theory and practice in two of the most important processes in the inorganic chemical industry: (1) the contact process for the production of sulfuric acid, and (2) the chlor-alkali process for the production of chlorine.

## Sulfuric Acid, the Most Important Chemical

The manufacture of sulfuric acid began more than 400 years ago, when the acid was known as oil of vitriol and was distilled from "green vitriol" $\left(\mathrm{FeSO}_{4} \cdot 7 \mathrm{H}_{2} \mathrm{O}\right)$. Considering its countless uses, it is not surprising that today sulfuric acid is produced throughout the world on a gigantic scale-more than 150 million tons a year. The green vitriol method and the many production methods used since have all been superseded by the modern contact process, which is based on the catalyzed oxidation of $\mathrm{SO}_{2}$. Here are the key steps.

1. Obtaining sulfur. In most countries today, the production of sulfuric acid starts with the production of elemental sulfur, often by the Claus process, in which the $\mathrm{H}_{2} \mathrm{~S}$ in "sour" natural gas is chemically separated and then oxidized:

$$
\begin{aligned}
& 2 \mathrm{H}_{2} \mathrm{~S}(g)+2 \mathrm{O}_{2}(g) \xrightarrow{\text { low temperature }} \frac{1}{8} \mathrm{~S}_{8}(g)+\mathrm{SO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g) \\
& 2 \mathrm{H}_{2} \mathrm{~S}(g)+\mathrm{SO}_{2}(g) \xrightarrow{\mathrm{Fe}_{2} \mathrm{O}_{3} \text { catalyst }} \frac{3}{8} \mathrm{~S}_{8}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
\end{aligned}
$$

Where natural gas is not abundant but natural underground deposits of the element are, sulfur is obtained by the Frasch process, a nonchemical method that tapsthesgdeposies. DAFole ris Idritled to thedeposit, and superheated water (about $160^{\circ} \mathrm{C}$ ) is pumped down two outer concentric pipes to melt the sulfur (Figure 22.22 A ). Then, a combination of the hydrostatic pressure in the outermost pipe and the pressure of compressed air sent through a narrow inner pipe forces the sulfur to the surface (Figure 22.22B and C). The costs of drilling, pumping, and supplying water ( $5 \times 10^{6}$ gallons per day) are balanced somewhat by the fact that the product is very pure $(\sim 99.7 \% \mathrm{~S})$.
2. From sulfur to sulfur dioxide. Once obtained, the sulfur is burned in air to form $\mathrm{SO}_{2}$ :

$$
\frac{1}{8} \mathrm{~S}_{8}(\mathrm{~s})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{SO}_{2}(\mathrm{~g}) \quad \Delta H^{\circ}=-297 \mathrm{~kJ}
$$

Some $\mathrm{SO}_{2}$ is also obtained from the roasting of metal sulfide ores. About $90 \%$ of processed sulfur is used in making sulfur dioxide for production of the allimportant sulfuric acid. Indeed, this end product from sulfur is central to so many chemical industries that a nation's level of sulfur production is a reliable indicator of its overall industrial capacity: the United States, Russia, Japan, and Germany are the top four sulfur producers.
3. From sulfur dioxide to trioxide. The contact process oxidizes $\mathrm{SO}_{2}$ with $\mathrm{O}_{2}$ to $\mathrm{SO}_{3}$ :

$$
\mathrm{SO}_{2}(g)+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \rightleftharpoons \mathrm{SO}_{3}(\mathrm{~g}) \quad \Delta H^{\circ}=-99 \mathrm{~kJ}
$$

The reaction is exothermic and very slow at room temperature. From Le Châtelier's principle (Section 17.6), we know that the yield of $\mathrm{SO}_{3}$ can be increased by (1) changing the temperature, (2) increasing the pressure (more moles of gas are on the left than on the right), or (3) adjusting the concentrations (adding excess $\mathrm{O}_{2}$ and removing $\mathrm{SO}_{3}$ ).

First, let's examine the temperature effect. Adding heat (raising the temperature) increases the frequency of $\mathrm{SO}_{2}-\mathrm{O}_{2}$ collisions and thus increases the rate of $\mathrm{SO}_{3}$ formation. However, because the formation of $\mathrm{SO}_{3}$ is exothermic, removing heat (lowering the temperature) shifts the equilibrium position to the right and

thus increases the yield of $\mathrm{SO}_{3}$. This is a classic situation that calls for use of a catalyst. By lowering the activation energy, a catalyst allows equilibrium to be reached more quickly and at a lower temperature; thus, rate and yield are optimized (Section 16.8). The catalyst in the contact process is $\mathrm{V}_{2} \mathrm{O}_{5}$ on inert silica, which is active between $400^{\circ} \mathrm{C}$ and $600^{\circ} \mathrm{C}$.

The pressure effect is small and economically not worth exploiting. The concentration effects are controlled by providing an excess of $\mathrm{O}_{2}$ in the form of a $5 / 1$ mixture of air to $\mathrm{SO}_{2}$, or about $1 / 1 \mathrm{O}_{2}$ to $\mathrm{SO}_{2}$, about twice as much $\mathrm{O}_{2}$ as is called for by the reaction stoichiometry. The mixture is passed over catalyst beds in four stages, and the $\mathrm{SO}_{3}$ is removed at several points to favor more $\mathrm{SO}_{3}$ formation. The overall yield of $\mathrm{SO}_{3}$ is $99.5 \%$.
4. From sulfur trioxide to acid. Sulfur trioxide is the anhydride of sulfuric acid, so a hydration step is next. However, $\mathrm{SO}_{3}$ cannot be added to water because, at the operating temperature, it would first meet water vapor, which catalyzes its polymerization to $\left(\mathrm{SO}_{3}\right)_{x}$, and results in a smoke of solid particles that makes poor contact with water and yields little acid. To prevent this, previously formed $\mathrm{H}_{2} \mathrm{SO}_{4}$ absorbs the $\mathrm{SO}_{3}$ and forms pyrosulfuric acid (or disulfuric acid, $\mathrm{H}_{2} \mathrm{~S}_{2} \mathrm{O}_{7}$; see margin), which is then hydrolyzed with sufficient water:

$$
\begin{aligned}
\mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(l) \text { [low yield] } \\
\mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{SO}_{4}(l) & \longrightarrow \mathrm{H}_{2} \mathrm{~S}_{2} \mathrm{O}_{7}(l) \\
\mathrm{H}_{2} \mathrm{~S}_{2} \mathrm{O}_{7}(l)+\mathrm{H}_{2} \mathrm{O}(l) & \longrightarrow 2 \mathrm{H}_{2} \mathrm{SO}_{4}(l)
\end{aligned}
$$

Figure 22.22 The Frasch process for mining elemental sulfur. This nonchemical process uses superheated water and compressed air to melt underground sulfur and bring it to the surface. A, Superheated water is forced down a drilled hole into the subterranean sulfur deposit, and the sulfur melts. B, Compressed air is sent down an inner pipe in the drilling apparatus to force up the molten sulfur. C, Sulfur obtained from the Frasch process.

disulfuric acid

Figure 22.23 The many indispensable applications of sulfuric acid.

The uses of sulfuric acid are legion, as Figure 22.23 indicates.
Sulfuric acid is remarkably inexpensive (about $\$ 150 /$ ton), largely because each step in the process is exothermic-burning S $\left(\Delta H^{\circ}=-297 \mathrm{~kJ} / \mathrm{mol}\right)$, oxidizing $\mathrm{SO}_{2}\left(\Delta H^{\circ}=-99 \mathrm{~kJ} / \mathrm{mol}\right)$, hydrating $\mathrm{SO}_{3}\left(\Delta H^{\circ}=-132 \mathrm{~kJ} / \mathrm{mol}\right)$-and the heat is a valuable byproduct. Three-quarters of the heat is sold as steam, and the rest of it is used to pump gases through the plant. A typical plant making 825 tons of $\mathrm{H}_{2} \mathrm{SO}_{4}$ per day produces enough steam to generate $7 \times 10^{6}$ watts of
electric power. PDF Enhancer

## The Chlor-Alkali Process

Chlorine is produced and used in amounts many times greater than all the other halogens combined, ranking among the top 10 chemicals produced in the United States. Its production methods depend on the oxidation of $\mathrm{Cl}^{-}$ion from NaCl .

Earlier, we discussed the Downs process for isolating sodium, which yields $\mathrm{Cl}_{2}$ gas as the other product (Section 22.4). The chlor-alkali process, which forms the basis of one of the largest inorganic chemical industries, electrolyzes concentrated aqueous NaCl to produce $\mathrm{Cl}_{2}$ and several other important chemicals. As you learned in Section 21.7, the electrolysis of aqueous NaCl does not yield both of the component elements. Because of the effects of overvoltage, $\mathrm{Cl}^{-}$ions rather than $\mathrm{H}_{2} \mathrm{O}$ molecules are oxidized at the anode. However, $\mathrm{Na}^{+}$ions are not reduced at the cathode because the half-cell potential $(-2.71 \mathrm{~V})$ is much more negative than that for reduction of $\mathrm{H}_{2} \mathrm{O}(-0.42 \mathrm{~V})$, even with the normal overvoltage (around -0.6 V ). Therefore, the half-reactions for electrolysis of aqueous NaCl are

$$
2 \mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{Cl}_{2}(g)+2 \mathrm{e}^{-} \quad E^{\circ}=1.36 \mathrm{~V} \quad \text { [anode; oxidation] }
$$

$$
\begin{array}{cc}
2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-} \longrightarrow 2 \mathrm{OH}^{-}(a q)+\mathrm{H}_{2}(g) & E \approx-1.0 \mathrm{~V} \text { [cathode; reduction] } \\
\hline 2 \mathrm{Cl}^{-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{OH}^{-}(a q)+\mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g) & E_{\text {cell }}=-1.0 \mathrm{~V}-1.36 \mathrm{~V}=-2.4 \mathrm{~V}
\end{array}
$$

To obtain commercially meaningful amounts of $\mathrm{Cl}_{2}$, however, a voltage almost twice this value and a current in excess of $3 \times 10^{4} \mathrm{~A}$ are used.

When we include the spectator ion $\mathrm{Na}^{+}$, the total ionic equation shows another important product made by the process:

$$
2 \mathrm{Na}^{+}(a q)+2 \mathrm{Cl}^{-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{Na}^{+}(a q)+2 \mathrm{OH}^{-}(a q)+\mathrm{H}_{2}(g)+\mathrm{Cl}_{2}(g)
$$

As Figure 22.24 shows, the sodium salts in the cathode compartment exist as an aqueous mixture of NaCl and NaOH ; the NaCl is removed by fractional crystallization. Thus, in this version of the chlor-alkali process, which uses an asbestos

diaphragm to separate the anode and cathode compartments, electrolysis of NaCl brines yields $\mathrm{Cl}_{2}, \mathrm{H}_{2}$, and industrial-grade NaOH , an important base. Like other reactive products, $\mathrm{H}_{2}$ and $\mathrm{Cl}_{2}$ are kept apart to prevent explosive recombination. Note the higher liquid level in the anode compartment. This slight hydrostatic pressure difference minimizes backflow of NaOH , which prevents the disproportionation (self-oxidation-reduction) reactions of $\mathrm{Cl}_{2}$ that occur in the presence of $\mathrm{OH}^{-}$(Section 14.9), such as

If high-purity NaOH is desired, a slightly different version, called the chloralkali mercury-cell process, is employed. Mercury is used as the cathode, which creates such a large overvoltage for reduction of $\mathrm{H}_{2} \mathrm{O}$ to $\mathrm{H}_{2}$ that the process does favor reduction of $\mathrm{Na}^{+}$. The sodium dissolves in the mercury to form sodium amalgam, $\mathrm{Na}(\mathrm{Hg})$. In the mercury-cell version, the half-reactions are

$$
\begin{array}{cl}
2 \mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{Cl}_{2}(g)+2 \mathrm{e}^{-} & \text {[anode; oxidation] } \\
2 \mathrm{Na}^{+}(a q)+2 \mathrm{e}^{-} \xrightarrow{\mathrm{Hg}} 2 \mathrm{Na}(\mathrm{Hg}) & \text { [cathode; reduction] }
\end{array}
$$

To obtain sodium hydroxide, the sodium amalgam is pumped out of the system and treated with $\mathrm{H}_{2} \mathrm{O}$, which is reduced by the Na :

$$
2 \mathrm{Na}(\mathrm{Hg})+2 \mathrm{H}_{2} \mathrm{O}(l) \xrightarrow{-\mathrm{Hg}} 2 \mathrm{Na}^{+}(a q)+2 \mathrm{OH}^{-}(a q)+\mathrm{H}_{2}(g)
$$

The mercury released in this step is recycled back to the electrolysis bath. Therefore, the products are the same in both versions, but the purity of NaOH from the mercury-cell version is much higher.

Despite the formation of purer NaOH , the mercury-cell method is being steadily phased out in the United States and has been eliminated in Japan for more than a decade. Cost is not the major reason for the phase-out, although the method does consume about $15 \%$ more electricity than the diaphragm-cell version. Rather, the problem is that as the mercury is recycled, some is lost in the industrial wastewater. On average, 200 g of Hg is lost per ton of $\mathrm{Cl}_{2}$ produced. In the 1980s, annual U.S. production via the mercury-cell method was 2.75 million tons of $\mathrm{Cl}_{2}$; thus, during that decade, $550,000 \mathrm{~kg}$ of this toxic heavy metal was flowing into U.S. waterways each year!

The newer chlor-alkali membrane-cell process replaces the diaphragm with a polymeric membrane to separate the cell compartments. The membrane allows only cations to move through it and only from anode to cathode compartments. Thus, as $\mathrm{Cl}^{-}$ions are removed at the anode through oxidation to $\mathrm{Cl}_{2}, \mathrm{Na}^{+}$ions

Figure 22.24 A diaphragm cell for the chlor-alkali process. This process uses concentrated aqueous NaCl to make $\mathrm{NaOH}, \mathrm{Cl}_{2}$, and $\mathrm{H}_{2}$ in an electrolytic cell. The difference in liquid level between compartments keeps a net movement of solution into the cathode compartment, which prevents reaction between $\mathrm{OH}^{-}$ and $\mathrm{Cl}_{2}$. The cathode electrolyte is concentrated and fractionally crystallized to give industrial-grade NaOH .
in the anode compartment move through the membrane to the cathode compartment and form an NaOH solution. In addition to forming purer NaOH than the older diaphragm-cell method, the membrane-cell process uses less electricity and eliminates the problem of Hg pollution. As a result, it has been adopted throughout much of the industrialized world.

## Section Summary

Sulfuric acid production starts with the extraction of sulfur, either by the oxidation of $\mathrm{H}_{2} \mathrm{~S}$ or the mining of sulfur deposits. The sulfur is roasted to $\mathrm{SO}_{2}$, which is oxidized to $\mathrm{SO}_{3}$ by the catalyzed contact process, which optimizes the yield at lower temperatures. Absorption of the $\mathrm{SO}_{3}$ into $\mathrm{H}_{2} \mathrm{SO}_{4}$, followed by hydration, forms sulfuric acid. • In the diaphragm-cell chlor-alkali process, aqueous NaCl is electrolyzed to form $\mathrm{Cl}_{2}, \mathrm{H}_{2}$, and low-purity NaOH . The mercury-cell method produces high-purity NaOH but has been almost completely phased out because of mercury pollution. The membrane-cell method requires less electricity and does not use Hg .

## Chapter Perspective

In this chapter, we took a realistic approach to the chemistry of the elements that allowed a glimpse at the intertwining natural cycles in which various elements take part, as well as at the ingenious methods that have been developed to extract them. The impact of living systems in general, and of humans in particular, on the origin and distribution of elements reveals a complex, evolving relationship. Understanding of and respect for that relationship are required for a healthy, productive balance between society's needs and the environment.

In Chapter 23, we conclude our exploration of the elements with a close look at the transition metals, a fascinating and extremely useful collection of metals. Then, in Chapter 24, we dive down to the atom's nuclear core and investigate its properties andits greatopotential for energylpreductionand medical science.

## CHAPTER REVIEW GUIDE

The following sections provide many aids to help you study this chapter. (Numbers in parentheses refer to pages, unless noted otherwise.)
Learning Objectives These are concepts and skills you should know after studying this chapter.

Relevant section numbers appear in parentheses.

## Understand These Concepts

1. How gravity, thermal convection, and elemental properties led to the silicate, sulfide, and iron phases and the predominance of certain elements in Earth's crust, mantle, and core (Section 22.1)
2. How organisms affect crustal abundances of elements, especially oxygen, carbon, calcium, and some transition metals; the onset of oxidation as an energy source (Section 22.1)
3. How atomic properties influence which elements have oxide ores and which have sulfide ores (Section 22.1)
4. The central role of $\mathrm{CO}_{2}$ and the importance of photosynthesis, respiration, and decay in the carbon cycle (Section 22.2)
5. The central role of $\mathrm{N}_{2}$ and the importance of atmospheric, industrial, and biological fixation in the nitrogen cycle (Section 22.2)
6. The absence of a gaseous component, the interactions of the inorganic and biological cycles, and the impact of humans on the phosphorus cycle (Section 22.2)
7. How pyro-, electro-, and hydrometallurgical processes are employed to extract a metal from its ore; the importance of the reduction step from compound to metal; refining and alloying processes (Section 22.3)
8. Functioning of the Downs cell for Na production and the application of Le Châtelier's principle for K production (Section 22.4) 9. How iron ore is reduced in a blast furnace and how pig iron is purified by the basic-oxygen process (Section 22.4)
9. How Fe is removed from copper ore and impure Cu is electrorefined (Section 22.4)
10. The importance of amphoterism in the Bayer process for isolating $\mathrm{Al}_{2} \mathrm{O}_{3}$ from bauxite; the significance of cryolite in the electrolytic step; the energy advantage of Al recycling (Section 22.4)
11. The steps in the Dow process for the extraction of Mg from seawater (Section 22.4)
12. How $\mathrm{H}_{2}$ production, whether by chemical or electrolytic means, is tied to $\mathrm{NH}_{3}$ production (Section 22.4)
13. How the kinetic isotope effect is applied to produce deuterium (Section 22.4)
14. How the Frasch process is used to obtain sulfur from natural deposits (Section 22.5)
15. The importance of equilibrium and kinetic factors in $\mathrm{H}_{2} \mathrm{SO}_{4}$ production (Section 22.5)
16. How overvoltage allows electrolysis of aqueous NaCl to form $\mathrm{Cl}_{2}$ gas in the chlor-alkali process; coproduction of NaOH ; comparison of diaphragm-cell, mercury-cell, and membrane-cell methods (Section 22.5)

Key Terms These important terms appear in boldface in the chapter and are defined again in the Glossary.

## PROBLEMS

Problems with colored numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and provide the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems incon起t. तhe comprehensive Problems are based on material from any section or previous chapter.

## How the Elements Occur in Nature

## - Concept Review Questions

22.1 Hydrogen is by far the most abundant element cosmically. In interstellar space, it exists mainly as $\mathrm{H}_{2}$. In contrast, on Earth, it exists very rarely as $\mathrm{H}_{2}$ and is ninth in abundance in the crust. Why is hydrogen so abundant in the universe? Why is hydrogen so rare as a diatomic gas in Earth's atmosphere?
22.2 Metallic elements can be recovered from ores that are oxides, carbonates, halides, or sulfides. Give an example of each type.
22.3 The location of elements in the regions of Earth has enormous practical importance. (a) Define the term differentiation, and explain which physical property of a substance is primarily responsible for this process. (b) What are the four most abundant elements in the crust? (c) Which element is abundant in the crust and mantle but not the core?
22.4 How does the position of a metal in the periodic table relate to whether it occurs primarily as an oxide or as a sulfide?

## Problems in Context

22.5 What material is the source for commercial production of each of the following elements: (a) aluminum; (b) nitrogen; (c) chlorine; (d) calcium; (e) sodium?
22.6 Aluminum is widely distributed throughout the world in the form of aluminosilicates. What property of these minerals prevents them from being a source of aluminum?
22.7 Describe two ways in which the biosphere has influenced the composition of Earth's crust.

## The Cycling of Elements Through the Environment

## Concept Review Questions

22.8 Use atomic and molecular properties to explain why life is based on carbon, rather than some other element such as silicon. 22.9 Define the term fixation. Name two elements that undergo Fienvienmentafixation. What natural forms of them are fixed? 22.10 Carbon dioxide enters the atmosphere by natural processes and from human activity. Why is the latter a cause of concern?
22.11 Diagrams of environmental cycles are simplified to omit minor contributors. For example, the production of lime from limestone is not shown in the cycle for carbon (Figure 22.5, p. 987). Which labeled category in the figure includes this process? Name two other processes that contribute to this category.
22.12 Describe three pathways for the utilization of atmospheric nitrogen. Is human activity a significant factor? Explain.
22.13 Why don't the N -containing species in Figure 22.6 (p. 989) include rings or long chains with $\mathrm{N}-\mathrm{N}$ bonds?
22.14 (a) Which region of Earth's crust is not involved in the phosphorus cycle? (b) Name two roles organisms play in the cycle.

## Problems in Context

22.15 Nitrogen fixation requires a great deal of energy because the $\mathrm{N}_{2}$ bond is strong. (a) How do the processes of atmospheric and industrial fixation reflect this energy requirement? (b) How do the thermodynamics of the two processes differ? (Hint: Examine the respective heats of formation.) (c) In view of the mild conditions for biological fixation, what must be the source of the "great deal of energy"? (d) What would be the most obvious environmental result of a low activation energy for $\mathrm{N}_{2}$ fixation?
22.16 The following steps are unbalanced half-reactions involved in the nitrogen cycle. Balance each half-reaction to show the number of electrons lost or gained, and state whether it is an oxidation or a reduction (all occur in acidic conditions):
(a) $\mathrm{N}_{2}(g) \longrightarrow \mathrm{NO}(g)$
(b) $\mathrm{N}_{2} \mathrm{O}(g) \longrightarrow \mathrm{NO}_{2}(g)$
(c) $\mathrm{NH}_{3}(a q) \longrightarrow \mathrm{NO}_{2}^{-}(a q)$
(d) $\mathrm{NO}_{3}{ }^{-}(a q) \longrightarrow \mathrm{NO}_{2}^{-}(a q)$
(e) $\mathrm{N}_{2}(g) \longrightarrow \mathrm{NO}_{3}{ }^{-}(a q)$
22.17 The use of silica to form slag in the production of phosphorus from phosphate rock was introduced by Robert Boyle more than 300 years ago. When fluorapatite $\left[\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F}\right]$ is used in phosphorus production, most of the fluorine atoms appear in the slag, but some end up in toxic and corrosive $\mathrm{SiF}_{4}(g)$.
(a) If $15 \%$ by mass of the fluorine in $100 . \mathrm{kg}$ of $\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{~F}$ forms $\mathrm{SiF}_{4}$, what volume of this gas is collected at 1.00 atm and the industrial furnace temperature of $1450 .{ }^{\circ} \mathrm{C}$ ?
(b) In some facilities, the $\mathrm{SiF}_{4}$ is used to produce sodium hexafluorosilicate $\left(\mathrm{Na}_{2} \mathrm{SiF}_{6}\right)$ which is sold for water fluoridation:

$$
\begin{aligned}
& 2 \mathrm{SiF}_{4}(g)+ \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \\
& \mathrm{Na}_{2} \mathrm{SiF}_{6}(a q)+\mathrm{SiO}_{2}(s)+\mathrm{CO}_{2}(g)+2 \mathrm{HF}(a q)
\end{aligned}
$$

How many cubic meters of drinking water can be fluoridated to a level of 1.0 ppm of $\mathrm{F}^{-}$using the $\mathrm{SiF}_{4}$ produced in part (a)?
22.18 An impurity sometimes found in $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ is $\mathrm{Fe}_{2} \mathrm{O}_{3}$, which is removed during the production of phosphorus as ferrophosphorus $\left(\mathrm{Fe}_{2} \mathrm{P}\right)$. (a) Why is this impurity troubling from an economic standpoint? (b) If 50 . metric tons of crude $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ contains $2.0 \% \mathrm{Fe}_{2} \mathrm{O}_{3}$ by mass and the overall yield of phosphorus is $90 . \%$, how many metric tons of $\mathrm{P}_{4}$ can be isolated?

## Metallurgy: Extracting a Metal from Its Ore

## - Concept Review Questions

22.19 Define: (a) ore; (b) mineral; (c) gangue; (d) brine.
22.20 Define: (a) roasting; (b) smelting; (c) flotation; (d) refining.
22.21 What factors determine which reducing agent is selected for producing a specific metal?
22.22 Use atomic properties to explain the reduction of a less active metal by a more active one: (a) in aqueous solution; (b) in the molten state. Give a specific example of eachatocess PDE
22.23 What class of element is obtained by oxidation of a mineral? What class of element is obtained by reduction of a mineral?

## Problems in Context

22.24 Which group of elements gives each of the following alloys: (a) brass; (b) stainless steel; (c) bronze; (d) sterling silver?

1. $\mathrm{Cu}, \mathrm{Ag}$
2. $\mathrm{Cu}, \mathrm{Sn}, \mathrm{Zn}$
3. $\mathrm{Ag}, \mathrm{Au}$
4. $\mathrm{Fe}, \mathrm{Cr}, \mathrm{Ni}$
5. Fe, V
6. $\mathrm{Cu}, \mathrm{Zn}$

## Tapping the Crust: Isolation and Uses of the Elements <br> - Concept Review Questions

22.25 How are each of the following involved in iron metallurgy: (a) slag; (b) pig iron; (c) steel; (d) basic-oxygen process?
22.26 What are the distinguishing features of each extraction process: pyrometallurgy, electrometallurgy, and hydrometallurgy? Explain briefly how the types of metallurgy are used in the production of (a) Fe ; (b) Na ; (c) Au ; (d) Al .
22.27 What property allows copper to be purified in the presence of iron and nickel impurities? Explain.
22.28 Why is cryolite used in the electrolysis of aluminum oxide?
22.29 (a) What is a kinetic isotope effect? (b) Do compounds of hydrogen exhibit a relatively large or small kinetic isotope effect? Explain. (c) Carbon compounds also exhibit a kinetic isotope effect. How do you expect it to compare in magnitude with that for hydrogen compounds? Why?
22.30 How is Le Châtelier's principle involved in the production of elemental potassium?

## - Problems in Context

22.31 Elemental Li and Na are prepared by electrolysis of a molten salt, whereas $\mathrm{K}, \mathrm{Rb}$, and Cs are prepared by chemical reduction.
(a) In general terms, explain why the alkali metals cannot be prepared by electrolysis of their aqueous salt solutions. (b) Use ionization energies (see the Family Portraits, pp. 572 and 576) to explain why calcium should not be able to isolate Rb from molten $\operatorname{RbX}(X=$ halide $)$. (c) Use physical properties to explain why calcium is used to isolate Rb from molten RbX . (d) Can Ca be used to isolate Cs from molten CsX? Explain.
22.32 A Downs cell operating at 77.0 A produces 31.0 kg of Na .
(a) What volume of $\mathrm{Cl}_{2}(\mathrm{~g})$ is produced at 1.0 atm and $540 .{ }^{\circ} \mathrm{C}$ ?
(b) How many coulombs were passed through the cell?
(c) How long did the cell operate?
22.33 (a) In the industrial production of iron, what is the reducing substance loaded into the blast furnace? (b) In addition to furnishing the reducing power, what other function does this substance serve? (c) What is the formula of the active reducing agent in the process? (d) Write equations for the stepwise reduction of $\mathrm{Fe}_{2} \mathrm{O}_{3}$ to iron in the furnace.
22.34 One of the substances loaded into a blast furnace is limestone, which produces lime in the furnace. (a) Give the chemical equation for the reaction forming lime. (b) Explain the purpose of lime in the furnace. The term flux is often used as a label for a substance acting as the lime does. What is the derivation of this word, and how does it relate to the function of the lime? (c) Write a chemical equation describing the action of lime flux.
22.35 The last step in the Dow process for the production of magnesium metal involves electrolysis of molten $\mathrm{MgCl}_{2}$.
(a) Why isn't the electrolysis carried out with aqueous $\mathrm{MgCl}_{2}$ ? What are the products of this aqueous electrolysis?
(b) Do the high temperatures required to melt $\mathrm{MgCl}_{2}$ favor productserreactantsfan: Consider the $\Delta H_{\mathrm{f}}^{\circ}$ of $\mathrm{MgCl}_{2}$.)
22.36 Iodine is the only halogen that occurs in a positive oxidation state, in $\mathrm{NaIO}_{3}$ impurities within Chile saltpeter, $\mathrm{NaNO}_{3}$.
(a) Is this mode of occurrence consistent with iodine's location in the periodic table? Explain.
(b) In the production of $\mathrm{I}_{2}, \mathrm{IO}_{3}^{-}$reacts with $\mathrm{HSO}_{3}{ }^{-}$:
$\mathrm{IO}_{3}{ }^{-}(a q)+\mathrm{HSO}_{3}^{-}(a q) \longrightarrow$
$\mathrm{HSO}_{4}{ }^{-}(a q)+\mathrm{SO}_{4}{ }^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{I}_{2}(s) \quad$ [unbalanced] Identify the oxidizing and reducing agents.
(c) If $0.78 \mathrm{~mol} \%$ of an $\mathrm{NaNO}_{3}$ deposit is $\mathrm{NaIO}_{3}$, how much $\mathrm{I}_{2}$ (in g ) can be obtained from 1.000 ton $(2000 \mathrm{lb}$ ) of the deposit?
22.37 Selenium is prepared by the reaction of $\mathrm{H}_{2} \mathrm{SeO}_{3}$ with gaseous $\mathrm{SO}_{2}$. (a) What redox process does the sulfur dioxide undergo? What is the oxidation state of sulfur in the product? (b) Given that the reaction occurs in acidic aqueous solution, what is the formula of the sulfur-containing species? (c) Write the balanced redox equation for the process.
$22.38 \mathrm{~F}_{2}$ and $\mathrm{Cl}_{2}$ are produced by electrolytic oxidation, whereas $\mathrm{Br}_{2}$ and $\mathrm{I}_{2}$ are produced by chemical oxidation of the halide ions in a concentrated aqueous solution (brine) by a more electronegative halogen. Give two reasons why $\mathrm{Cl}_{2}$ isn't prepared this way.
22.39 Silicon is prepared by the reduction of $\mathrm{K}_{2} \mathrm{SiF}_{6}$ with Al . Write the equation for this reaction. (Hint: Can $\mathrm{F}^{-}$be oxidized in this reaction? Can $\mathrm{K}^{+}$be reduced?)
22.40 What is the mass percent of iron in each of the following iron ores: $\mathrm{Fe}_{2} \mathrm{O}_{3}, \mathrm{Fe}_{3} \mathrm{O}_{4}, \mathrm{FeS}_{2}$ ?
22.41 Phosphorus is one of the impurities present in pig iron that is removed in the basic-oxygen process. Assuming phosphorus is present as P atoms, write equations for its oxidation and subsequent reaction in the basic slag.
22.42 The final step in the smelting of $\mathrm{FeCuS}_{2}$ is

$$
\mathrm{Cu}_{2} \mathrm{~S}(s)+2 \mathrm{Cu}_{2} \mathrm{O}(s) \longrightarrow 6 \mathrm{Cu}(l)+\mathrm{SO}_{2}(g)
$$

(a) Give the oxidation states of copper in $\mathrm{Cu}_{2} \mathrm{~S}, \mathrm{Cu}_{2} \mathrm{O}$, and Cu .
(b) What are the oxidizing and reducing agents in this reaction?
22.43 Use equations to show how acid-base properties are used to separate $\mathrm{Fe}_{2} \mathrm{O}_{3}$ and $\mathrm{TiO}_{2}$ from $\mathrm{Al}_{2} \mathrm{O}_{3}$ in the Bayer process.
22.44 A piece of Al with a surface area of $2.5 \mathrm{~m}^{2}$ is anodized to produce a film of $\mathrm{Al}_{2} \mathrm{O}_{3}$ that is $23 \mu\left(23 \times 10^{-6} \mathrm{~m}\right)$ thick.
(a) How many coulombs flow through the cell in this process (assume that the density of the $\mathrm{Al}_{2} \mathrm{O}_{3}$ layer is $3.97 \mathrm{~g} / \mathrm{cm}^{3}$ )?
(b) If it takes 18 min to produce this film, what current must flow through the cell?
22.45 The production of $\mathrm{H}_{2}$ gas by the electrolysis of water typically requires about 400 kJ of energy per mole.
(a) Use the relationship between work and cell potential (Section 21.4) to calculate the minimum work needed to form 1.0 mol of $\mathrm{H}_{2}$ gas at a cell potential of 1.24 V .
(b) What is the energy efficiency of the cell operation?
(c) Find the cost of producing $500 . \mathrm{mol}$ of $\mathrm{H}_{2}$ if electricity is $\$ 0.06$ per kilowatt $\cdot$ hour ( 1 watt $\cdot$ second $=1$ joule).
22.46 (a) What are the components of the reaction mixture following the water-gas shift reaction? (b) Explain how zeolites (Gallery, p. 593) are used to purify the $\mathrm{H}_{2}$ formed.
22.47 Metal sulfides are often first converted to oxides by roasting in air and then reduced with carbon to produce the metal. Why aren't the metal sulfides reduced directly by carbon to yield $\mathrm{CS}_{2}$ ? Give a thermodynamic analysis of both processes for ZnS .

## Chemical Manufacturing: Two Case Studies

## Concept Review Questions

22.48 Explain in detail why a catalyst is used to produce $\mathrm{SO}_{3}$.
22.49 Among the exothermic steps in the manufacture of sulfuric acid is the process of hydrating $\mathrm{SO}_{3}$. (a) Write two chemical reactions that show this process. (b) Why is the direct reaction of $\mathrm{SO}_{3}$ with water not feasible?
22.50 Why is commercial $\mathrm{H}_{2} \mathrm{SO}_{4}$ so inexpensive?
22.51 (a) What are the three commercial products formed in the chlor-alkali process? (b) State an advantage and a disadvantage of the mercury-cell method for this process.

## Problems in Context

22.52 For the reaction of $\mathrm{SO}_{2}$ to $\mathrm{SO}_{3}$ at standard conditions, (a) Calculate $\Delta G^{\circ}$ at $25^{\circ} \mathrm{C}$. Is the reaction spontaneous? (b) Why is the reaction not performed at $25^{\circ} \mathrm{C}$ ? (c) Is the reaction spontaneous at $500 .{ }^{\circ} \mathrm{C}$ ? (Assume $\Delta H^{\circ}$ and $\Delta S^{\circ}$ are constant with changing T.) (d) Compare $K$ at $500 .{ }^{\circ} \mathrm{C}$ and at $25^{\circ} \mathrm{C}$. (e) What is the highest $T$ at which the reaction is spontaneous?
22.53 If a chlor-alkali cell used a current of $3 \times 10^{4} \mathrm{~A}$, how many pounds of $\mathrm{Cl}_{2}$ would be produced in a typical 8-h operating day?
22.54 The products of the chlor-alkali process, $\mathrm{Cl}_{2}$ and NaOH , are kept separated. (a) Why is this necessary when $\mathrm{Cl}_{2}$ is the desired product? (b) $\mathrm{ClO}^{-}$or $\mathrm{ClO}_{3}^{-}$may form by disproportionation of $\mathrm{Cl}_{2}$ in basic solution. What determines which product forms? (c) What mole ratio of $\mathrm{Cl}_{2}$ to $\mathrm{OH}^{-}$will produce $\mathrm{ClO}^{-}$? $\mathrm{ClO}_{3}{ }^{-}$?

## Comprehensive Problems

22.55 The key step in the manufacture of sulfuric acid is the oxidation of sulfur dioxide in the presence of a catalyst, such as $\mathrm{V}_{2} \mathrm{O}_{5}$. At $727^{\circ} \mathrm{C}, 0.010 \mathrm{~mol}$ of $\mathrm{SO}_{2}$ is injected into an empty
2.00-L container ( $K_{\mathrm{p}}=3.18$ ). (a) What is the equilibrium pressure of $\mathrm{O}_{2}$ that is needed to maintain a $1 / 1$ mole ratio of $\mathrm{SO}_{3}$ to $\mathrm{SO}_{2}$ ? (b) What is the equilibrium pressure of $\mathrm{O}_{2}$ needed to maintain a $95 / 5$ mole ratio of $\mathrm{SO}_{3}$ to $\mathrm{SO}_{2}$ ?
22.56 Many metal oxides are converted to the free metal by reduction with other elements, such as C or Si . For each of the following reactions, calculate the temperature at which the reduction occurs spontaneously:
(a) $\mathrm{MnO}_{2}(s) \longrightarrow \mathrm{Mn}(s)+\mathrm{O}_{2}(g)$
(b) $\mathrm{MnO}_{2}(s)+2 \mathrm{C}$ (graphite) $\longrightarrow \mathrm{Mn}(s)+2 \mathrm{CO}(g)$
(c) $\mathrm{MnO}_{2}(s)+\mathrm{C}$ (graphite) $\longrightarrow \mathrm{Mn}(s)+\mathrm{CO}_{2}(g)$
(d) $\mathrm{MnO}_{2}(s)+\mathrm{Si}(s) \longrightarrow \mathrm{Mn}(s)+\mathrm{SiO}_{2}(s)$
22.57 Tetraphosphorus decaoxide $\left(\mathrm{P}_{4} \mathrm{O}_{10}\right)$ is made from phosphate rock and used as a drying agent in the laboratory.
(a) Write a balanced equation for its reaction with water.
(b) What is the pH of a solution formed from the addition of 8.5 g of $\mathrm{P}_{4} \mathrm{O}_{10}$ in sufficient water to form 0.750 L ? (See Table 18.5, p. 803, for additional information.)
22.58 Heavy water $\left(\mathrm{D}_{2} \mathrm{O}\right)$ is used to make deuterated chemicals.
(a) What major species, aside from the starting compounds, do you expect to find in a solution of $\mathrm{CH}_{3} \mathrm{OH}$ and $\mathrm{D}_{2} \mathrm{O}$ ?
(b) Write equations to explain how these various species arise. (Hint: Consider the autoionization of both components.)
22.59 A blast furnace uses $\mathrm{Fe}_{2} \mathrm{O}_{3}$ to produce 8400. t of Fe per day.
(a) What mass of $\mathrm{CO}_{2}$ is produced each day?
(b) Compare this amount of $\mathrm{CO}_{2}$ with that produced by 1.0 million automobiles, each burning 5.0 gal of gasoline a day. Assume that gasoline has the formula $\mathrm{C}_{8} \mathrm{H}_{18}$ and a density of $0.74 \mathrm{~g} / \mathrm{mL}$, and that it burns completely. (Note that U.S. gasoline Fronsumptione is quer $4 \times 10^{8} \mathrm{gal} / \mathrm{day}$.)
22.60 A major use of $\mathrm{Cl}_{2}$ is in the manufacture of vinyl chloride, the monomer of poly(vinyl chloride). The two-step sequence for formation of vinyl chloride is depicted below.

(a) Write a balanced equation for each step. (b) Write the overall equation. (c) What type of organic reaction is shown in step 1 ? (d) What type of organic reaction is shown in step 2? (e) If each molecule depicted in the initial reaction mixture represents 0.15 mol of substance, what mass (in g) of vinyl chloride forms? 22.61 In the production of magnesium, $\mathrm{Mg}(\mathrm{OH})_{2}$ is precipitated by using $\mathrm{Ca}(\mathrm{OH})_{2}$, which itself is "insoluble." (a) Use $K_{\text {sp }}$ values to show that $\mathrm{Mg}(\mathrm{OH})_{2}$ can be precipitated from seawater in which $\left[\mathrm{Mg}^{2+}\right]$ is initially 0.052 M . (b) If the seawater is saturated with $\mathrm{Ca}(\mathrm{OH})_{2}$, what fraction of the $\mathrm{Mg}^{2+}$ is precipitated?
22.62 The Ostwald process for the production of $\mathrm{HNO}_{3}$ is
(1) $4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) \xrightarrow{\mathrm{Pt} / \mathrm{Rh} \text { catalyst }} 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)$
(2) $2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)$
(3) $3 \mathrm{NO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{HNO}_{3}(a q)+\mathrm{NO}(g)$
(a) Describe the nature of the change that occurs in step 3.
(b) Write an overall equation that includes $\mathrm{NH}_{3}$ and $\mathrm{HNO}_{3}$ as the only nitrogen-containing species.
(c) Calculate $\Delta H_{\mathrm{rxn}}^{\circ}$ (in $\mathrm{kJ} / \mathrm{mol} \mathrm{N}$ atoms) for this reaction at $25^{\circ} \mathrm{C}$.
22.63 Step 1 of the Ostwald process for nitric acid production is

$$
4 \mathrm{NH}_{3}(g)+5 \mathrm{O}_{2}(g) \xrightarrow{\mathrm{Pt} / \text { Rh catalyst }} 4 \mathrm{NO}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)
$$

An unwanted side reaction for this step is

$$
4 \mathrm{NH}_{3}(g)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{~N}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(g)
$$

(a) Calculate $K_{\mathrm{p}}$ for these two $\mathrm{NH}_{3}$ oxidations at $25^{\circ} \mathrm{C}$.
(b) Calculate $K_{\mathrm{p}}$ for these two $\mathrm{NH}_{3}$ oxidations at $900 .{ }^{\circ} \mathrm{C}$.
(c) $\mathrm{The} \mathrm{Pt} / \mathrm{Rh}$ catalyst is one of the most efficient in the chemical industry, achieving $96 \%$ yield in 1 millisecond of contact with the reactants. However, at normal operating conditions ( 5 atm and $850^{\circ} \mathrm{C}$ ), about 175 mg of Pt is lost per metric ton ( t$)$ of $\mathrm{HNO}_{3}$ produced. If the annual U.S. production of $\mathrm{HNO}_{3}$ is $1.01 \times 10^{7} \mathrm{t}$ and the market price of Pt is $\$ 1260 /$ troy oz, what is the annual cost of the lost $\mathrm{Pt}(1 \mathrm{~kg}=32.15$ troy oz $)$ ?
(d) Because of the high price of Pt , a filtering unit composed of ceramic fiber is often installed, which recovers as much as $75 \%$ of the lost Pt. What is the value of the Pt captured by a recovery unit with $72 \%$ efficiency?
22.64 The compounds $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4}$ and $\mathrm{NH}_{4}\left(\mathrm{H}_{2} \mathrm{PO}_{4}\right)$ are water-soluble fertilizers. (a) Which has the higher mass \% of P ? (b) Why might the one with the lower mass $\%$ of P be preferred?
22.65 Several transition metals are prepared by reduction of the metal halide with magnesium. Titanium is prepared by the Kroll method, in which ore (ilmenite) is converted to the gaseous chloride, which is then reduced to Ti metal by molten Mg (see p. 1008). Assuming yields of $84 \%$ for step 1 and $93 \%$ for step 2, and an excess of the other reactants, what mass of Ti metal can be prepared from 21.5 metric tons of ilmenite?
22.66 The production of $\mathrm{S}_{8}$ from the $\mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})$ found in natural ga deposits occurs through the Claus process (Seetion2259. PDE
(a) Use these two unbalanced steps to write an overall balanced equation for this process:
(1) $\mathrm{H}_{2} \mathrm{~S}(g)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{S}_{8}(g)+\mathrm{SO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(g)$
(2) $\mathrm{H}_{2} \mathrm{~S}(g)+\mathrm{SO}_{2}(g) \longrightarrow \mathrm{S}_{8}(g)+\mathrm{H}_{2} \mathrm{O}(g)$
(b) Write the overall reaction with $\mathrm{Cl}_{2}$ as the oxidizing agent instead of $\mathrm{O}_{2}$. Use thermodynamic data to show whether $\mathrm{Cl}_{2}(\mathrm{~g})$ can be used to oxidize $\mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})$.
(c) Why is oxidation by $\mathrm{O}_{2}$ preferred to oxidation by $\mathrm{Cl}_{2}$ ?
22.67 Acid mine drainage (AMD) occurs when geologic deposits containing pyrite $\left(\mathrm{FeS}_{2}\right)$ are exposed to oxygen and moisture. AMD is generated in a multistep process catalyzed by acidophilic (acid-loving) bacteria. Balance each step and identify those that increase acidity:
(1) $\mathrm{FeS}_{2}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{Fe}^{2+}(a q)+\mathrm{SO}_{4}{ }^{2-}(a q)$
(2) $\mathrm{Fe}^{2+}(a q)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{Fe}^{3+}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$
(3) $\mathrm{Fe}^{3+}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Fe}(\mathrm{OH})_{3}(s)+12 \mathrm{H}^{+}(a q)$
(4) $\mathrm{FeS}_{2}(s)+\mathrm{Fe}^{3+}(a q) \longrightarrow \mathrm{Fe}^{2+}(a q)+\mathrm{SO}_{4}{ }^{2-}(a q)$
22.68 Based on a concentration of $0.065 \mathrm{~g} \mathrm{Br}^{-} / \mathrm{L}$, the ocean is estimated to have $\$ 391,000,000$ of $\mathrm{Br}_{2} / \mathrm{mi}^{3}$ at recent prices. (a) What is the price per gram of $\mathrm{Br}_{2}$ ? (b) Find the mass (in g) of $\mathrm{AgNO}_{3}$ needed to precipitate $90.0 \%$ of the $\mathrm{Br}^{-}$in 1.00 L of ocean water. (c) Use Appendix C to find how low $\left[\mathrm{Cl}^{-}\right]$must be to prevent the unwanted precipitation of AgCl . (d) Given a $\left[\mathrm{Cl}^{-}\right]$ of about $0.3 M$, is precipitation with silver ion a practical way to obtain bromine from the ocean? Explain.
22.69 Below $912^{\circ} \mathrm{C}$, pure iron crystallizes in a body-centered cubic structure (ferrite) with a density of $7.86 \mathrm{~g} / \mathrm{cm}^{3}$; from $912^{\circ} \mathrm{C}$ to $1394^{\circ} \mathrm{C}$, it adopts a face-centered cubic structure (austenite) with a density of $7.40 \mathrm{~g} / \mathrm{cm}^{3}$. Both types of iron form
interstitial alloys with carbon. The maximum amount of carbon is 0.0218 mass \% in ferrite and 2.08 mass \% in austenite. Calculate the density of each alloy.
22.70 Why isn't nitric acid produced by oxidizing $\mathrm{N}_{2}$ as follows?
(3)

$$
\begin{equation*}
\frac{2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{NO}_{2}(g)}{3 \mathrm{~N}_{2}(g)+6 \mathrm{O}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 4 \mathrm{HNO}_{3}(a q)+2 \mathrm{NO}(g)} \tag{1}
\end{equation*}
$$

(Hint: Evaluate the thermodynamics of each step.)
22.71 Before the development of the Downs cell, the Castner cell was used for the industrial production of Na metal. The Castner cell was based on the electrolysis of molten NaOH .
(a) Write balanced cathode and anode half-reactions for this cell. (b) A major problem with this cell was that the water produced at one electrode diffused to the other and reacted with the Na . If all the water produced reacted with Na , what would be the maximum efficiency of the Castner cell expressed as moles of Na produced per mole of electrons flowing through the cell?
22.72 When gold ores are leached with $\mathrm{CN}^{-}$solutions, gold forms a complex ion, $\mathrm{Au}(\mathrm{CN})_{2}{ }^{-}$. (a) Find $E_{\text {cell }}$ for the oxidation in air $\left(P_{\mathrm{O}_{2}}=0.21\right)$ of Au to $\mathrm{Au}^{+}$in basic ( pH 13.55 ) solution with $\left[\mathrm{Au}^{+}\right]=0.50 \mathrm{M}$. Is the reaction $\mathrm{Au}^{+}(a q)+\mathrm{e}^{-} \longrightarrow \mathrm{Au}(s)$, $E^{\circ}=1.68 \mathrm{~V}$, spontaneous? (b) How does formation of the complex ion change $E^{\circ}$ so that the oxidation can be accomplished?
22.73 Nitric oxide occurs in the tropospheric nitrogen cycle, but it destroys ozone in the stratosphere. (a) Write equations for its reaction with ozone and for the reverse reaction. (b) Given that the forward and reverse steps are first order in each component, write general date laws for them. (c) Calculate $\Delta G^{\circ}$ for this reaction at $280 . \mathrm{K}$, the average temperature in the stratosphere. (Assume that the $\Delta H^{\circ}$ and $S^{\circ}$ values in Appendix B do not change with temperature.) (d) What ratio of rate constants is consistent with $K$ at this temperature?
22.74 A key part of the carbon cycle is the fixation of $\mathrm{CO}_{2}$ by photosynthesis to produce carbohydrates and oxygen gas.
(a) Using the formula $\left(\mathrm{CH}_{2} \mathrm{O}\right)_{n}$ to represent a carbohydrate, write a balanced equation for the photosynthetic reaction.
(b) If a tree fixes 48 g of $\mathrm{CO}_{2}$ per day, what volume of $\mathrm{O}_{2}$ gas measured at 1.0 atm and $78^{\circ} \mathrm{F}$ does the tree produce per day?
(c) What volume of air $\left(0.035 \mathrm{~mol} \% \mathrm{CO}_{2}\right)$ at the same conditions contains this amount of $\mathrm{CO}_{2}$ ?
22.75 Farmers use ammonium sulfate as a fertilizer. In the soil, nitrifying bacteria oxidize $\mathrm{NH}_{4}{ }^{+}$to $\mathrm{NO}_{3}{ }^{-}$, a groundwater contaminant that causes methemoglobinemia ("blue baby" syndrome). The World Health Organization standard for maximum $\left[\mathrm{NO}_{3}{ }^{-}\right]$ in groundwater is $45 \mathrm{mg} / \mathrm{L}$. A farmer adds 210 kg of $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}$ to a field and $37 \%$ is oxidized to $\mathrm{NO}_{3}{ }^{-}$. What is the groundwater $\left[\mathrm{NO}_{3}{ }^{-}\right]$(in $\mathrm{mg} / \mathrm{L}$ ) if $1000 . \mathrm{m}^{3}$ of the water is contaminated?
22.76 In the 1980s, U.S. Fish and Wildlife Service researchers found high mortality among newborn coots and ducks in parts of California. U.S. Geological Survey scientists later found the cause to be a high selenium concentration in agricultural drainage water. Balance these half-reactions in the selenium cycle:
(a) $\mathrm{Se}^{2-}(a q) \longrightarrow \mathrm{Se}(s)$
(b) $\mathrm{SeO}_{3}{ }^{2-}(a q) \longrightarrow \mathrm{SeO}_{4}{ }^{2-}(a q)$
(c) $\mathrm{SeO}_{4}{ }^{2-}(a q) \longrightarrow \mathrm{Se}(s)$
22.77 The key reaction (unbalanced) in the manufacture of synthetic cryolite for aluminum electrolysis is
$\mathrm{HF}(g)+\mathrm{Al}(\mathrm{OH})_{3}(s)+\mathrm{NaOH}(a q) \longrightarrow \mathrm{Na}_{3} \mathrm{AlF}_{6}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$

Assuming a $95.6 \%$ yield of dried, crystallized product, what mass (in kg ) of cryolite can be obtained from the reaction of 365 kg of $\mathrm{Al}(\mathrm{OH})_{3}, 1.20 \mathrm{~m}^{3}$ of $50.0 \%$ by mass aqueous NaOH ( $d=1.53 \mathrm{~g} / \mathrm{mL}$ ), and $265 \mathrm{~m}^{3}$ of gaseous HF at 305 kPa and $91.5^{\circ} \mathrm{C}$ ? (Assume that the ideal gas law holds.)
22.78 Because of their different molar masses, $\mathrm{H}_{2}$ and $\mathrm{D}_{2}$ effuse at different rates (Section 5.6). (a) If it takes 16.5 min for 0.10 mol of $\mathrm{H}_{2}$ to effuse, how long does it take for 0.10 mol of $\mathrm{D}_{2}$ to do so in the same apparatus at the same $T$ and $P$ ? (b) How many effusion steps does it take to separate an equimolar mixture of $\mathrm{D}_{2}$ and $\mathrm{H}_{2}$ to $99 \mathrm{~mol} \%$ purity?
22.79 The disproportionation of CO to graphite and $\mathrm{CO}_{2}$ is thermodynamically favored but slow.
(a) What does this mean in terms of the magnitudes of the equilibrium constant $(K)$, rate constant $(k)$, and activation energy $\left(E_{\mathrm{a}}\right)$ ?
(b) Write a balanced equation for the disproportionation of CO.
(c) Calculate $K_{\mathrm{c}}$ at 298 K . (d) Calculate $K_{\mathrm{p}}$ at 298 K .
22.80 The overall cell reaction for aluminum production is

$$
2 \mathrm{Al}_{2} \mathrm{O}_{3}\left(\text { in }^{\left.\mathrm{Na}_{3} \mathrm{AlF}_{6}\right)+3 \mathrm{C}(\text { graphite }) \longrightarrow 4 \mathrm{Al}(l)+3 \mathrm{CO}_{2}(\mathrm{~g}), ~}\right.
$$

(a) Assuming $100 \%$ efficiency, how many metric tons ( $t$ ) of $\mathrm{Al}_{2} \mathrm{O}_{3}$ are consumed per metric ton of Al produced?
(b) Assuming $100 \%$ efficiency, how many metric tons of the graphite anode are consumed per metric ton of Al produced?
(c) Actual conditions in an aluminum plant require 1.89 t of $\mathrm{Al}_{2} \mathrm{O}_{3}$ and 0.45 t of graphite per metric ton of Al . What is the percent yield of Al with respect to $\mathrm{Al}_{2} \mathrm{O}_{3}$ ?
(d) What is the percent yield of Al with respect to graphite?
(e) What volume of $\mathrm{CO}_{2}\left(\mathrm{in} \mathrm{m}^{3}\right)$ is produced per metric ton of Al at operating conditions of $960 .{ }^{\circ} \mathrm{C}$ and exactly 1 atm ?
22.81 World production of chromite ( $\mathrm{E} \mathrm{AR}_{2} \mathrm{O}_{4}$ ) main oreof chromium, was $1.5 \times 10^{7}$ metric tons in 2003. To isolate chromium, a mixture of chromite and sodium carbonate is heated in air to form sodium chromate, iron(III) oxide, and carbon dioxide. The sodium chromate is dissolved in water, and this solution is acidified with sulfuric acid to produce the less soluble sodium dichromate. The sodium dichromate is filtered out and reduced with carbon to produce chromium(III) oxide, sodium carbonate, and carbon monoxide. The chromium(III) oxide is then reduced to chromium with aluminum metal. (a) Write balanced equations for each step. (b) What mass of chromium (in kg ) could be prepared from the 2003 world production of chromite?
22.82 Like heavy water ( $\mathrm{D}_{2} \mathrm{O}$ ), so-called "semi-heavy water" (HDO) undergoes H/D exchange. The scenes below depict an initial mixture of HDO and $\mathrm{H}_{2}$ reaching equlibrium.

(a) Write the balanced equation for the reaction. (b) Is the value of $K$ greater or less than 1 ? (c) If each molecule depicted represents 0.10 M , calculate $K$.
22.83 Even though most metal sulfides are sparingly soluble in water, their solubilities differ by several orders of magnitude. This difference is sometimes used to separate the metals by con-
trolling the pH . Use the following data to find the pH at which you can separate $0.10 \mathrm{MCu}^{2+}$ and $0.10 \mathrm{M}^{2+}$ :
Saturated $\mathrm{H}_{2} \mathrm{~S}=0.10 \mathrm{M}$
$K_{\mathrm{a} 1}$ of $\mathrm{H}_{2} \mathrm{~S}=9 \times 10^{-8}$

$$
K_{\text {sp }} \text { of } \mathrm{NiS}=1.1 \times 10^{-18}
$$

$$
\begin{aligned}
& K_{\mathrm{a} 2} \text { of } \mathrm{H}_{2} \mathrm{~S}=1 \times 10^{-17} \\
& K_{\mathrm{sp}} \text { of } \mathrm{CuS}=8 \times 10^{-34}
\end{aligned}
$$

22.84 Ores with as little as $0.25 \%$ by mass of copper are used as sources of the metal. (a) How many kilograms of such an ore would be needed for another Statue of Liberty, which contains $2.0 \times 10^{5} \mathrm{lb}$ of copper? (b) If the mineral in the ore is chalcopyrite $\left(\mathrm{FeCuS}_{2}\right)$, what is the mass \% of chalcopyrite in the ore?
22.85 How does acid rain affect the leaching of phosphate into groundwater from terrestrial phosphate rock? Calculate the solubility of $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ in each of the following: (a) Pure water, pH 7.0 (Assume that $\mathrm{PO}_{4}{ }^{3-}$ does not react with water.) (b) Moderately acidic rainwater, pH 4.5 (Hint: Assume that all the phosphate exists in the form that predominates at this pH .)
22.86 The lead(IV) oxide used in car batteries is prepared by coating the electrode plate with PbO and then oxidizing it to lead dioxide $\left(\mathrm{PbO}_{2}\right)$. Despite its name, $\mathrm{PbO}_{2}$ has a nonstoichiometric ratio of lead to oxygen of about $1 / 1.98$. In fact, the holes in the $\mathrm{PbO}_{2}$ crystal structure due to missing O atoms are responsible for the oxide's conductivity. (a) What is the mole $\%$ of O missing from the $\mathrm{PbO}_{2}$ structure? (b) What is the molar mass of the nonstoichiometric compound?
22.87 Chemosynthetic bacteria reduce $\mathrm{CO}_{2}$ by "splitting" $\mathrm{H}_{2} \mathrm{~S}(g)$ instead of the $\mathrm{H}_{2} \mathrm{O}(g)$ used by photosynthetic organisms. Compare the free energy change for splitting $\mathrm{H}_{2} \mathrm{~S}$ with that for splitting $\mathrm{H}_{2} \mathrm{O}$. Is there an advantage to using $\mathrm{H}_{2} \mathrm{~S}$ instead of $\mathrm{H}_{2} \mathrm{O}$ ?
F22.88 Silyer has a face-centered cubic structure with a unit cell - Redge qengtrof 408.6 pm . Sterling silver is a substitutional alloy that contains $7.5 \%$ copper atoms. Assuming the unit cell remains the same, find the density of silver and of sterling silver.
22.89 Earth's mass is estimated to be $5.98 \times 10^{24} \mathrm{~kg}$, and titanium represents $0.05 \%$ by mass of this total. (a) How many moles of Ti are present? (b) If half of the Ti is found as ilmenite $\left(\mathrm{FeTiO}_{3}\right)$, what mass of ilmenite is present? (c) If the airline and auto industries use $1.00 \times 10^{5}$ tons of Ti per year, how many years would it take to use up all the $\mathrm{Ti}(1 \mathrm{ton}=2000 \mathrm{lb})$ ?
22.90 In 1790, Nicolas Leblanc found a way to form $\mathrm{Na}_{2} \mathrm{CO}_{3}$ from NaCl . His process, now obsolete, consisted of three steps:

$$
\begin{aligned}
2 \mathrm{NaCl}(s)+\mathrm{H}_{2} \mathrm{SO}_{4}(a q) & \longrightarrow \mathrm{Na}_{2} \mathrm{SO}_{4}(a q)+2 \mathrm{HCl}(g) \\
\mathrm{Na}_{2} \mathrm{SO}_{4}(s)+2 \mathrm{C}(s) & \longrightarrow \mathrm{Na}_{2} \mathrm{~S}(s)+2 \mathrm{CO}_{2}(g) \\
\mathrm{Na}_{2} \mathrm{~S}(s)+\mathrm{CaCO}_{3}(s) & \longrightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(s)+\mathrm{CaS}(s)
\end{aligned}
$$

(a) Write a balanced overall equation for the process.
(b) Calculate the $\Delta H_{\mathrm{f}}^{\circ}$ of CaS if $\Delta H_{\mathrm{rxn}}^{\circ}$ is $351.8 \mathrm{~kJ} / \mathrm{mol}$.
(c) Is the overall process spontaneous at standard-state conditions and 298 K ?
(d) How many grams of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ form from 250. g of NaCl if the process is $73 \%$ efficient?
22.91 Limestone $\left(\mathrm{CaCO}_{3}\right)$ is the second most abundant mineral on Earth after $\mathrm{SiO}_{2}$. For many uses, it is first decomposed thermally to quicklime $(\mathrm{CaO}) . \mathrm{MgO}$ is prepared similarly from $\mathrm{MgCO}_{3}$. (a) At what $T$ is each decomposition spontaneous? (b) Quicklime reacts with $\mathrm{SiO}_{2}$ to form a slag $\left(\mathrm{CaSiO}_{3}\right)$, a byproduct of steelmaking. In 2003, the total steelmaking capacity of the U.S. steel industry was $2,370,000$ tons per week, but only $84 \%$ of this capacity was utilized. If $50 . \mathrm{kg}$ of slag is produced per ton of steel, what mass (in kg ) of limestone was used to make slag in 2003?

## 23

Traces of lons and the Beauty of Gems Much of the color in precious and semiprecious stones comes from trace amounts of transition-metal ions in mineral structures. $\mathrm{The} \mathrm{Cr}^{3+}$ ion within beryllium aluminum silicate makes emeralds green, and the same ion in aluminum oxide makes rubies red; a mixture of $\mathrm{Fe}^{2+}$, $\mathrm{Fe}^{3+}$, and $\mathrm{Ti}^{4+}$ ions in aluminum oxide makes sapphires blue. In this chapter, we examine the transition metals and some of their numerous applications as well as the remarkable structures and properties of their compounds.

0ur exploration of the elements to this point is far from complete; in fact, we have skirted the majority of them and some of the most familiar. Whereas most important uses of the main-group elements involve their compounds, the transition elements are remarkably useful in their uncombined form. Figure 23.1 shows that the transition elements (transition metals) make up the $d$ block ( B groups) and $f$ block (inner transition elements).

In Chapter 22, you saw how two of the most important-copper and ironare extracted from their ores. Aside from those two, with their countless essential uses, many other transition elements are indispensable as well: chromium in automobile parts, gold and silver in jewelry, tungsten in lightbulb filaments, platinum in automobile catalytic converters, titanium in bicycle frames and aircraft parts, and zinc in batteries, to mention just a few of the better known elements. You may be less aware of zirconium in nuclear-reactor liners, vanadium in axles and crankshafts, molybdenum in boiler plates, nickel in coins, tantalum in organreplacement parts, palladium in telephone-relay contacts-the list goes on and on. As ions, they provide fascinating insights into chemical bonding and structure, while many also play vital roles in living organisms.

IN THIS CHAPTER ... We first discuss some atomic, physical, and chemical properties of the transition elements and then focus on the chemistry of four familiar ones: chromium, manganese, silver, and mercury. Next, we concentrate on the most distinctive feature of transition element chemistry, the formation of coordination compounds, substances that contain complex ions. We consider two models that explain the striking colors of these compounds, as well as their magnetic properties and structures, and then end with some essential biochemical functions of transition metal ions.

Figure 23.1 The transition elements (d block) and inner transition elements ( $f$ block) in the periodic table.

## Concepts \& Skills to Review before you study this chapter

- properties of light (Section 7.1)
- electron shielding of nuclear charge (Section 8.2)
- electron configuration, ionic size, and magnetic behavior (Sections 8.3 to 8.5)
- valence bond theory (Section 11.1)
- constitutional, geometric, and optical isomerism (Section 15.2)
- Lewis acid-base concepts (Section 18.9)
- complex-ion formation (Section 19.4)
- redox behavior and standard electrode potentials (Section 21.3)

Figure 23.2 The Period 4 transition metals. Samples of all ten elements appear as pure metals, in chunk or powder form, in periodic-table order on this and the facing page.

### 23.1 PROPERTIES OF THE TRANSITION ELEMENTS

The transition elements differ considerably in physical and chemical behavior from the main-group elements. In some ways, they are more uniform: main-group elements in each period change from metal to nonmetal, but all transition elements are metals. In other ways, the transition elements are more diverse: most main-group ionic compounds are colorless and diamagnetic, but many transition metal compounds are highly colored and paramagnetic. We first discuss electron configurations of the atoms and ions, and then examine certain key properties of transition elements, with an occasional comparison to the main-group elements.

## Electron Configurations of the Transition Metals and Their lons

As with any of the elements, the properties of the transition elements and their compounds arise largely from the electron configurations of their atoms (Section 8.3) and ions (Section 8.5). The $d$-block (B-group) elements occur in four series that lie within Periods 4 through 7 between the last $n s$-block element [Group $2 \mathrm{~A}(2)$ ] and the first $n p$-block element [Group 3A(13)]. Each series represents the filling of five $d$ orbitals and, thus, contains ten elements. In 1996 and 1997, elements 110 through 112 were synthesized in particle accelerators, so the Period 7 series is 7 completeothup ill $\mathrm{F}^{40}$ dibleck tansition elements are known. Lying between the first and second members of the $d$-block transition series in Periods 6 and 7 are the inner transition elements, whose $f$ orbitals are being filled.

Even though there are several exceptions, in general, the condensed groundstate electron configuration for the elements in each $d$-block series is

$$
\text { [noble gas] } n s^{2}(n-1) d^{x} \text {, with } n=4 \text { to } 7 \text { and } x=1 \text { to } 10
$$

In Periods 6 and 7, the condensed configuration includes the $f$ sublevel:

$$
\text { [noble gas] } n s^{2}(n-2) f^{14}(n-1) d^{x} \text {, with } n=6 \text { or } 7
$$

The partial (valence-level) electron configuration for the $d$-block elements excludes the noble gas core and the filled inner $f$ sublevel:

$$
n s^{2}(n-1) d^{x}
$$

The first transition series occurs in Period 4 and consists of scandium (Sc) through zinc (Zn) (Figure 23.2 and Table 23.1). Scandium has the electron configuration $[\mathrm{Ar}] 4 s^{2} 3 d^{1}$, and the addition of one electron at a time (along with one proton in the nucleus) first half-fills, then fills, the $3 d$ orbitals across the periodic table to zinc. Recall that chromium and copper are two exceptions to this general pattern: the $4 s$ and $3 d$ orbitals in Cr are both half-filled to give $[\mathrm{Ar}] 4 s^{1} 3 d^{5}$, and the $4 s$ in Cu is half-filled to give $[\mathrm{Ar}] 4 s^{1} 3 d^{10}$. The reasons for these exceptions involve the change in relative energies of the $4 s$ and $3 d$ orbitals as electrons are added across the series and the unusual stability of half-filled and filled sublevels.

Transition metal ions form through the loss of the ns electrons before the $(n-1) d$ electrons. Therefore, the electron configuration of $\mathrm{Ti}^{2+}$ is $[\mathrm{Ar}] 3 d^{2}$, not [Ar] $4 s^{2}$, and $\mathrm{Ti}^{2+}$ is referred to as a $d^{2}$ ion. Ions of different metals with the same configuration often have similar properties. For example, both $\mathrm{Mn}^{2+}$ and $\mathrm{Fe}^{3+}$ are $d^{5}$ ions; both have pale colors in aqueous solution and form complex ions with similar magnetic properties.

Table 23.1 shows a general pattern in number of unpaired electrons (or halffilled orbitals) across the Period 4 transition series. Note that the number increases

in the first half of the series and, when pairing begins, decreases through the second half. As you'll see, it is the electron configuration of the transition metal atom that correlates with physical properties of the element, such as density and magnetic behavior, whereas it is the electron configuration of the ion that determines the properties of the compounds.

## SAMPLE PROBLEM 23.1 Writing Electron Configurations of Transition Metal Atoms and Ions

PROBLEM Write condensed electron configurations for the following: (a) Zr ; (b) $\mathrm{V}^{3+}$; (c) $\mathrm{Mo}^{3+}$. (Assume that elements in higher periods behave like those in Period 4.)

PLAN We locate the element in the periodic table and count its position in the respective transition series. These elements are in Periods 4 and 5, so the general configuration is [noble gas] $n s^{2}(n-1) d^{x}$. For the ions, we recall that $n s$ electrons are lost first.
SOLUTION (a) Zr is the second element in the $4 d$ series: $[\mathrm{Kr}] 5 s^{2} 4 d^{2}$.
(b) V is the third element in the $3 d$ series: $[\mathrm{Ar}] 4 s^{2} 3 d^{3}$. In forming $\mathrm{V}^{3+}$, three electrons are lost (two $4 s$ and one $3 d$ ), so $\mathrm{V}^{3+}$ is a $d^{2}$ ion: $[\mathrm{Ar}] 3 d^{2}$.
(c) Mo lies below Cr in Group $6 \mathrm{~B}(6)$, so we expect the same exception as for Cr . Thus, Mo is $[\mathrm{Kr}] 5 s^{1} 4 d^{5}$. To form the ion, Mo loses the one $5 s$ and two of the $4 d$ electrons, so $\mathrm{Mo}^{3+}$ is a $d^{3}$ ion: $[\mathrm{Kr}] 4 d^{3}$.
CHECK Figure 8.11 (p. 314) shows we're correct for the atoms. Be sure that charge plus number of $d$ electrons in the ion equals the sum of outer $s$ and $d$ electrons in the atom.
FOLLOW-UP PROBLEM 23.1 Write partial electron configurations for the following: (a) $\mathrm{Ag}^{+} ;$(b) $\mathrm{Cd}^{2+}$; (c) $\mathrm{Ir}^{3+}$.

## Atomic and Physical Properties of the Transition Elements

The atomic properties of the transition elements contrast in several ways with those of a comparable set of main-group elements.

Trends Across a Period Consider the variations in atomic size, electronegativity, and ionization energy across Period 4 (Figure 23.3):

- Atomic size. Atomic size decreases overall across the period (Figure 23.3A). However, there is a smooth, steady decrease across the main groups because the electrons are added to outer orbitals, which shield the increasing nuclear charge poorly. This steady decrease is suspended throughout the transition series, where atomic size decreases at first but then remains fairly constant. Recall that the $d$ electrons fill inner orbitals, so they shield outer electrons from the increasing nuclear charge very efficiently. As a result, the outer $4 s$ electrons are not pulled closer.

- Electronegativity. Electronegativity generally increases across the period but, once again, the transition elements exhibit a relatively small change in electronegativity (Figure 23.3B), consistent with the relatively small change in size.

B Electronegativity In contrast, the main groups show a steady, much steeper increase between the metal potassium (0.8) and the nonmetal bromine (2.8). The transition elements all have intermediate electronegativity values, much like the large, metallic members of Groups $3 \mathrm{~A}(13)$ to $5 \mathrm{~A}(15)$.

- Ionization energy. The ionization energies of the Period 4 main-group elements rise steeply from left to right, more than tripling from potassium ( $419 \mathrm{~kJ} / \mathrm{mol}$ ) to krypton

C First ionization energy ( $\mathrm{k} / / \mathrm{mol}$ )
Figure 23.3 Horizontal trends in key atomic properties of the Period 4
elements. The atomic radius (A), electronegativity (B), and first ionization energy (C) of the elements in Period 4 are shown as posts of different heights, with darker shading for the transition series. The transition elements exhibit smaller, less regular changes for these properties than do the main-group elements.

AOM the poorly shielded, increasing nuclear charge. In the transition metals, however, the first ionization energies increase relatively little because the inner $3 d$ electrons shield effectively (Figure 23.3C); thus, the outer $4 s$ electron experiences only a slightly higher effective nuclear charge. [Recall from Section 8.4 that the drop at Group $3 \mathrm{~A}(13)$ occurs because it is relatively easy to remove the first electron from the outer $n p$ orbital.]

Trends Within a Group Vertical trends for transition elements are also different from those for the main groups.

- Atomic size. As expected, atomic size increases from Period 4 to 5, as it does for the main-group elements, but there is virtually no size increase from Period 5 to 6 (Figure 23.4A). Remember that the lanthanides, with their buried $4 f$ sublevel, appear between the $4 d$ (Period 5) and 5d (Period 6) series. Therefore, an element in Period 6 is separated from the one above it in Period 5 by 32 elements (ten $4 d$, six $5 p$, two $6 s$, and fourteen $4 f$ orbitals) instead of just 18 . The extra shrinkage that results from the increase in nuclear charge due to the addition of 14 protons is called the lanthanide contraction. By coincidence, this decrease is about equal to the normal increase between periods, so the Periods 5 and 6 transition elements have about the same atomic sizes.
- Electronegativity. The vertical trend in electronegativity seen in most transition groups is opposite the trend in main groups. Here, we see an increase in electronegativity from Period 4 to Period 5, but then no further increase in Period 6 (Figure 23.4B). The heavier elements, especially gold ( $\mathrm{EN}=2.4$ ), become quite electronegative, with values exceeding those of most metalloids and even some nonmetals (e.g., EN of Te and of $\mathrm{P}=2.1$ ). (In fact, gold forms the saltlike CsAu and the $\mathrm{Au}^{-}$ion, which exists in liquid ammonia.) Although the

Figure 23.4 Vertical trends in key properties within the transition elements. The trends are unlike those for the main-group elements in several ways: A, The second and third members of a transition metal group are nearly the same size. B, Electronegatityincreases down a
atomic size increases slightly from the top to the bottom of a group, the nuclear charge increases much more. Therefore, the heavier transition metals exhibit more covalent character in their bonds and attract electrons more strongly than do main-group metals.

- Ionization energy. The relatively small increase in size combined with the relatively large increase in nuclear charge also explains why the first ionization energy generally increases down a transition group (Figure 23.4C). This trend also runs counter to the pattern in the main groups, in which heavier members are so much larger that their outer electron is easier to remove.
- Density. Atomic size, and therefore volume, is inversely related to density. Across a period, densities increase, then level off, and finally dip a bit at the end of a series (Figure 23.4D). Down a transition group, densities increase dramatically because atomic volumes change little from Period 5 to 6, but atomic masses increase significantly. As a result, the Period 6 series contains some of the densest elements known: tungsten, rhenium, osmium, iridium, platinum, and gold have densities about 20 times that of water and twice that of lead.

## Chemical Properties of the Transition Metals

Like their atomic and physical properties, the chemical properties of the transition elements are very different from those of the main-group elements. Let's examine the key properties in the Period 4 transition series and then see how behavior changes within a group.

Figure 23.5 Aqueous oxoanions of transition elements. A, Often, a given transition element has multiple oxidation states. Here, Mn is shown in the +2 $\left(\mathrm{Mn}^{2+}\right.$, left $)$, the $+6\left(\mathrm{MnO}_{4}{ }^{2-}\right.$, middle $)$, and the +7 states $\left(\mathrm{MnO}_{4}{ }^{-}\right.$, right). B, The highest possible oxidation state equals the group number in these oxoanions: +5 in $\mathrm{VO}_{4}{ }^{3-}$ (left), +6 in $\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}$ (middle), and +7 in $\mathrm{MnO}_{4}^{-}$(right).

Oxidation States One of the most characteristic chemical properties of the transition metals is the occurrence of multiple oxidation states. For example, in their compounds, vanadium exhibits two common positive oxidation states, chromium three, and manganese three (Figure 23.5A), and many other oxidation states are seen less often. Since the $n s$ and $(n-1) d$ electrons are so close in energy, transition elements can use all or most of these electrons in bonding. This behavior is markedly different from that of the main-group metals, which display one or, at most, two oxidation states in their compounds.

The highest oxidation state of elements in Groups 3B(3) through 7B(7) is equal to the group number, as shown in Table 23.2. These oxidation states are seen when the elements combine with highly electronegative oxygen or fluorine. For instance, in the oxoanion solutions shown in Figure 23.5B, vanadium occurs as the vanadate ion $\left(\mathrm{VO}_{4}{ }^{3-} ; \mathrm{O} . \mathrm{N}\right.$. of $\left.\mathrm{V}=+5\right)$, chromium occurs as the dichromate ion $\left(\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}\right.$; O.N. of $\left.\mathrm{Cr}=+6\right)$, and manganese occurs as the permanganate ion $\left(\mathrm{MnO}_{4}{ }^{-}\right.$; O.N. of $\left.\mathrm{Mn}=+7\right)$. Elements in Groups 8B(8), 8B(9), and $8 \mathrm{~B}(10)$ exhibit fewer oxidation states, and the highest state is less common and never equal to the group number. For example, we never encounter iron in the +8 state and only rarely in the +6 state. The +2 and +3 states are the most common ones for iron* and cobalt, and the +2 state is most common for nickel, copper, and zinc. The +2 oxidation state is common because $n s^{2}$ electrons are readily lost.

Copper, silver, and gold (the coinage metals) in Group $1 \mathrm{~B}(11)$ are unusual. Although copper has a fairly common oxidation state of +1 , which results from loss of its single $4 s$ electron, its most common state is +2 . Silver behaves more predictably, exhibiting primarily the +1 oxidation state. Gold exhibits the +3 state and, less often, the +1 state. Zinc, cadmium, and mercury in Group 2B(12) exhibit the +2 state, but mercury also exhibits the +1 state in the $\mathrm{Hg}_{2}{ }^{2+}$ ion, withtspoo Hgebnit Ennancer
*Iron may seem to have unusual oxidation states in the common ores magnetite $\left(\mathrm{Fe}_{3} \mathrm{O}_{4}\right)$ and pyrite $\left(\mathrm{FeS}_{2}\right)$, but this is not really the case. In magnetite, one-third of the metal ions are $\mathrm{Fe}^{2+}$ and two-thirds are $\mathrm{Fe}^{3+}$, which is equivalent to a $1 / 1$ ratio of FeO to $\mathrm{Fe}_{2} \mathrm{O}_{3}$ and gives an overall formula of $\mathrm{Fe}_{3} \mathrm{O}_{4}$. Pyrite contains $\mathrm{Fe}^{2+}$ combined with the disulfide ion, $\mathrm{S}_{2}{ }^{2-}$.
${ }^{+}$Some evidence suggests that the $\mathrm{Hg}_{2}{ }^{2+}$ ion may exist as an Hg atom bonded to an $\mathrm{Hg}^{2+}$ ion, with the atom donating its two 6s electrons for the covalent bond.

[^34]Metallic Behavior and Reducing Strength Atomic size and oxidation state have a major effect on the nature of bonding in transition metal compounds. Like the metals in Groups $3 \mathrm{~A}(13), 4 \mathrm{~A}(14)$, and $5 \mathrm{~A}(15)$, the transition elements in their lower oxidation states behave chemically more like metals. That is, ionic bonding is more prevalent for the lower oxidation states, and covalent bonding is more prevalent for the higher states. For example, at room temperature, $\mathrm{TiCl}_{2}$ is an ionic solid, whereas $\mathrm{TiCl}_{4}$ is a molecular liquid. In the higher oxidation states, the atoms have higher charge densities, so they polarize the electron clouds of the nonmetal ions more strongly and the bonding becomes more covalent. For the same reason, the oxides become less basic as the oxidation state increases: TiO is weakly basic in water, whereas $\mathrm{TiO}_{2}$ is amphoteric (reacts with both acid and base).

Table 23.3 shows the standard electrode potentials of the Period 4 transition metals in their +2 oxidation state in acid solution. Note that, in general, reducing strength decreases across the series. All the Period 4 transition metals, except copper, are active enough to reduce $\mathrm{H}^{+}$from aqueous acid to form hydrogen gas. In contrast to the rapid reaction at room temperature of the Group $1 \mathrm{~A}(1)$ and $2 \mathrm{~A}(2)$ metals with water, however, the transition metals have an oxide coating that allows rapid reaction only with hot water or steam.
Color and Magnetism of Compounds Most main-group ionic compounds are colorless because the metal ion has a filled outer level (noble gas electron configuration). With only much higher energy orbitals available to receive an excited electron, the ion does not absorb visible light. In contrast, electrons in a partially filled $d$ sublevel can absorb visible wavelengths and move to slightly higher energy $d$ orbitals. As a result, many transition metal compounds have striking colors. Exceptions are the compounds of scandium, titanium(IV), and zinc, which
 $\mathrm{Ti}^{4+}:[\mathrm{Ar}] 3 d^{0}$ ) or a filled one ( $\mathrm{Zn}^{2+}:[\mathrm{Ar}] 3 d^{10}$ ) (Figure 23.6).

Magnetic properties are also related to sublevel occupancy (Section 8.5). Recall that a paramagnetic substance has atoms or ions with unpaired electrons, which cause it to be attracted to an external magnetic field. A diamagnetic substance has only paired electrons, so it is unaffected (or slightly repelled) by a magnetic field. Most main-group metal ions are diamagnetic for the same reason they are colorless: all their electrons are paired. In contrast, many transition metal compounds are paramagnetic because of their unpaired d electrons. For example, $\mathrm{MnSO}_{4}$ is paramagnetic, but $\mathrm{CaSO}_{4}$ is diamagnetic. The $\mathrm{Ca}^{2+}$ ion has the electron configuration of argon, whereas $\mathrm{Mn}^{2+}$ has a $d^{5}$ configuration. Transition metal ions with a $d^{0}$ or $d^{10}$ configuration are also colorless and diamagnetic.

Table 23.3 Standard Electrode Potentials of Period $4 \mathrm{M}^{2+}$ Ions

| Half-Reaction | $\boldsymbol{E}^{\circ}(\mathbf{V})$ |
| :--- | ---: |
| $\mathrm{Ti}^{2+}(a q)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{Ti}(s)$ | -1.63 |
| $\mathrm{~V}^{2+}(a q)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{V}(s)$ | -1.19 |
| $\mathrm{Cr}^{2+}(a q)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{Cr}(s)$ | -0.91 |
| $\mathrm{Mn}^{2+}(a q)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{Mn}(s)$ | -1.18 |
| $\mathrm{Fe}^{2+}(a q)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{Fe}(s)$ | -0.44 |
| $\mathrm{Co}^{2+}(a q)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{Co}(s)$ | -0.28 |
| $\mathrm{Ni}^{2+}(a q)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{Ni}(s)$ | -0.25 |
| $\mathrm{Cu}^{2+}(a q)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{Cu}(s)$ | 0.34 |
| $\mathrm{Zn}^{2+}(a q)+2 \mathrm{e}^{-} \rightleftharpoons \mathrm{Zn}(s)$ | -0.76 |

Figure $\mathbf{2 3 . 6}$ Colors of representative compounds of the Period 4 transition metals. Staggered from left to right, the compounds are scandium oxide (white), titanium(IV) oxide (white), vanadyl sulfate dihydrate (light blue), sodium chromate (yellow), manganese(II) chloride
tetrahydrate (light pink), potassium ferricyanide (red-orange), cobalt(II) chloride hexahydrate (violet), nickel(II) nitrate hexahydrate (green), copper(II) sulfate pentahydrate (blue), and zinc sulfate heptahydrate (white).

Chemical Behavior Within a Group The increase in reactivity going down a group of main-group metals, as shown by the decrease in first ionization energy ( $\mathrm{IE}_{1}$ ), does not occur going down a group of transition metals. Consider the chromium $(\mathrm{Cr})$ group $[6 \mathrm{~B}(6)]$, which shows a typical pattern (Table 23.4). $\mathrm{IE}_{1}$ increases down the group, which makes the two heavier metals less reactive than the lightest one. Chromium is also a much stronger reducing agent than molybdenum (Mo) or tungsten (W), as shown by the standard electrode potentials.

## Table 23.4 Some Properties of Group 6B(6) Elements

| Element | Atomic <br> Radius (pm) | $\mathbf{I E}_{\mathbf{1}}(\mathbf{k J} / \mathbf{m o l})$ | $\mathbf{E}^{\circ}(\mathbf{V})$ for <br> $\mathbf{M}^{3+}(\mathrm{aq}) \mid \mathbf{M}(\mathbf{s})$ |
| :--- | :---: | :---: | :---: |
| Cr | 128 | 653 | -0.74 |
| Mo | 139 | 685 | -0.20 |
| W | 139 | 770 | -0.11 |

The similarity in atomic size of Period 5 and 6 members also leads to similar chemical behavior, a fact that has some important practical consequences. Because Mo and W compounds behave similarly, for example, their ores often occur together in nature, which makes the elements very difficult to separate from each other. The same situation occurs with zirconium and hafnium in Group 4B(4) and with niobium and tantalum in Group 5B(5).

## Section Summary

All transition elements are metals. - Atoms of the $d$-block elements have $(n-1) d$ orbitals being filled, and their ions have an empty $n s$ orbital. • Unlike the trends in the main-group lements, atomicisize, erectronegativity, and first ionization energy change relatively little across a transition series. Because of the lanthanide contraction, atomic size changes little from Period 5 to 6 in a transition metal group; thus, electronegativity, first ionization energy, and density increase down a group. • Transition metals typically have several oxidation states, with the +2 state most common. The elements exhibit more metallic behavior in their lower states. - Most Period 4 transition metals are active enough to reduce hydrogen ion from acid solution. - Many transition metal compounds are colored and paramagnetic because the metal ion has unpaired $d$ electrons.

### 23.2 THE INNER TRANSITION ELEMENTS

The 14 lanthanides-cerium $(\mathrm{Ce} ; Z=58)$ through lutetium ( $\mathrm{Lu} ; Z=71$ )—lie between lanthanum $(Z=57)$ and hafnium $(Z=72)$ in the third $d$-block transition series. Below them are the 14 radioactive actinides, thorium ( $\mathrm{Th} ; Z=90$ ) through lawrencium $(\mathrm{Lr} ; Z=103)$, which lie between actinium (Ac; $Z=89$ ) and rutherfordium ( $\mathrm{Rf} ; Z=104$ ). The lanthanides and actinides are called inner transition elements because, in most cases, their seven inner $4 f$ or $5 f$ orbitals are being filled.

## The Lanthanides

The lanthanides are sometimes called the rare earth elements, a term referring to their presence in unfamiliar oxides, but they are actually not rare at all. Cerium (Ce), for instance, ranks $26^{\text {th }}$ in natural abundance (by mass $\%$ ) and is five times more abundant than lead. All the lanthanides are silvery, high-melting $\left(800^{\circ} \mathrm{C}\right.$ to $1600^{\circ} \mathrm{C}$ ) metals. Their chemical properties represent an extreme case of the small variations typical of transition elements in a period or a group, which makes the lanthanides very difficult to separate.

The natural co-occurrence of the lanthanides arises because they exist as $\mathrm{M}^{3+}$ ions of very similar radii in their common ores. Most lanthanides have the groundstate electron configuration $[\mathrm{Xe}] 6 s^{2} 4 f^{x} 5 d^{0}$, where $x$ varies across the series. The three exceptions $(\mathrm{Ce}, \mathrm{Gd}$, and Lu ) have a single electron in one of their $5 d$ orbitals: Ce ( $[\mathrm{Xe}] 6 s^{2} 4 f^{1} 5 d^{1}$ ) forms a stable $4+$ ion with an empty $\left(f^{0}\right)$ sublevel, and the $\mathrm{Gd}^{3+}$ and $\mathrm{Lu}^{3+}$ ions have a stable half-filled $\left(f^{7}\right)$ or filled $\left(f^{14}\right)$ sublevel.

Lanthanide compounds and their mixtures have many uses. Several oxides are used for tinting sunglasses and welder's goggles and for adding color to the fluorescent powder coatings in TV screens. High-quality camera lenses incorporate $\mathrm{La}_{2} \mathrm{O}_{3}$ because of its extremely high index of refraction. Samarium forms an alloy with cobalt, $\mathrm{SmCo}_{5}$, that is used in the strongest known permanent magnet (see Sample Problem 23.2). Two industrial uses account for more than $60 \%$ of rare earth applications. In gasoline refining, the zeolite catalysts (Gallery, p. 593) used to "crack" hydrocarbon components into smaller molecules contain $5 \%$ by mass rare earth oxides. In steelmaking, a mixture of lanthanides, called misch metal, is used to remove carbon impurities from molten iron and steel.

## SAMPLE PROBLEM 23.2 Finding the Number of Unpaired Electrons

PROBLEM The alloy $\mathrm{SmCo}_{5}$ forms a permanent magnet because both samarium and cobalt have unpaired electrons. How many unpaired electrons are in the Sm atom $(Z=62)$ ?
PLAN We write the condensed electron configuration of Sm and then, using Hund's rule and the aufbau principle, place the electrons in a partial orbital diagram and count the unpaired electrons.
SOLUTION Samarium is the eighth element after Xe. Two electrons go into the $6 s$ sublevel. In general, the $4 f$ sublevel fills before the $5 d$ (among the lanthanides, only $\mathrm{Ce}, \mathrm{Gd}$, and Lu have $5 d$ electrons), so the remaining electrons go into the $4 f$. Thus, Sm is [Xe] $6 s^{2} 4 f^{6}$. There are seven $f$ orbitals, so each of the six $f$ electrons enters a separate orbital:

Thus, Sm has six unpaired electrons.
CHECK Six $4 f \mathrm{e}^{-}$plus two $6 s \mathrm{e}^{-}$plus the $54 \mathrm{e}^{-}$in Xe gives 62, the atomic number of Sm .
FOLLOW-UP PROBLEM 23.2 How many unpaired electrons are in the $\mathrm{Er}^{3+}$ ion?

## The Actinides

All actinides are radioactive. Like the lanthanides, they share very similar physical and chemical properties. Thorium and uranium occur in nature, but the transuranium elements, those with $Z$ greater than 92 , have been synthesized in high-energy particle accelerators, some in only tiny amounts (Section 24.3). In fact, macroscopic samples of mendelevium (Md), nobelium (No), and lawrencium ( Lr ) have never been seen. The actinides that have been isolated are silvery and chemically reactive and, like the lanthanides, form highly colored compounds. The actinides and lanthanides have similar outer-electron configurations. Although the +3 oxidation state is characteristic of the actinides, as it is for the lanthanides, other states also occur. For example, uranium exhibits +3 through +6 states, with the +6 state the most prevalent; thus, the most common oxide of uranium is $\mathrm{UO}_{3}$.

## Section Summary

There are two series of inner transition elements. The lanthanides ( $4 f$ series) have a common +3 oxidation state and exhibit very similar properties. - The actinides ( $5 f$ series) are radioactive. All actinides have a +3 oxidation state; several, including uranium, have higher states as well.

### 23.3 HIGHLIGHTS OF SELECTED TRANSITION METALS

Let's investigate several transition elements, focusing on the general patterns in the aqueous chemistry of each. We examine chromium and manganese from Period 4, silver from Period 5, and mercury from Period 6.

## Chromium

Chromium is a very shiny, silvery metal, whose name (from the Greek chroma, "color") refers to its many colorful compounds. A solution of $\mathrm{Cr}^{3+}$ is deep violet, for example, and a trace of $\mathrm{Cr}^{3+}$ in the $\mathrm{Al}_{2} \mathrm{O}_{3}$ crystal structure gives ruby its beautiful red hue. Chromium readily forms a thin, adherent, transparent coating of $\mathrm{Cr}_{2} \mathrm{O}_{3}$ in air, making the metal extremely useful as an attractive protective coating on easily corroded metals, such as iron. "Stainless" steels often contain as much as $18 \%$ chromium by mass and are highly resistant to corrosion.

With six valence electrons ( $[\mathrm{Ar}] 4 s^{1} 3 d^{5}$ ), chromium occurs in all possible positive oxidation states, but the three most important are $+2,+3$, and +6 (see Table 23.2). In its three common oxides, chromium exhibits the pattern seen in many elements: nonmetallic character and oxide acidity increase with metal oxidation state. Chromium(II) oxide ( CrO ) is basic and largely ionic. It forms an insoluble hydroxide in neutral or basic solution but dissolves in acidic solution to yield the $\mathrm{Cr}^{2+}$ ion:

$$
\mathrm{CrO}(s)+2 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Cr}^{2+}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Chromium(III) oxide $\left(\mathrm{Cr}_{2} \mathrm{O}_{3}\right)$ is amphoteric, dissolving in acid to yield the violet $\mathrm{Cr}^{3+}$ ion,

$$
\mathrm{Cr}_{2} \mathrm{O}_{3}(s)+6 \mathrm{H}^{+}(a q) \longrightarrow 2 \mathrm{Cr}^{3+}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l)
$$

and in base to form the green $\mathrm{Cr}(\mathrm{OH})_{4}{ }^{-}$ion:

## 

Thus, chromium in its +3 state is similar to the main-group metal aluminum in several respects, including its amphoterism (Section 19.4).

Deep-red chromium(VI) oxide $\left(\mathrm{CrO}_{3}\right)$ is covalent and acidic, forming chromic acid $\left(\mathrm{H}_{2} \mathrm{CrO}_{4}\right)$ in water,

$$
\mathrm{CrO}_{3}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{CrO}_{4}(a q)
$$

which yields the yellow chromate ion $\left(\mathrm{CrO}_{4}{ }^{2-}\right)$ in base:

$$
\mathrm{H}_{2} \mathrm{CrO}_{4}(a q)+2 \mathrm{OH}^{-}(a q) \longrightarrow \mathrm{CrO}_{4}^{2-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)
$$

In acidic solution, the chromate ion immediately forms the orange dichromate ion $\left(\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}\right.$ ):

$$
2 \mathrm{CrO}_{4}^{2-}(a q)+2 \mathrm{H}^{+}(a q) \rightleftharpoons \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Because both ions contain chromium(VI), this is not a redox reaction; rather, it is a dehydration-condensation, as you can see from the structures in Figure 23.7. Hydrogen-ion concentration controls the equilibrium position: yellow $\mathrm{CrO}_{4}{ }^{2-}$ predominates at high pH , and orange $\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}$ at low pH . The bright colors of chromium(VI) compounds lead to their wide use in pigments for artist's paints and ceramic glazes. Lead chromate (chrome yellow) is also used in the yellow stripes that delineate traffic lanes.

Chromium metal and the $\mathrm{Cr}^{2+}$ ion are potent reducing agents. The metal displaces hydrogen from dilute acids to form blue $\mathrm{Cr}^{2+}(a q)$, which reduces $\mathrm{O}_{2}$ in air within minutes to form the violet $\mathrm{Cr}^{3+}$ ion:

$$
4 \mathrm{Cr}^{2+}(a q)+\mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q) \longrightarrow 4 \mathrm{Cr}^{3+}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l) \quad E_{\text {overall }}^{\circ}=1.64 \mathrm{~V}
$$

Chromium(VI) compounds in acid solution are strong oxidizing agents (concentrated solutions are extremely corrosive!), the chromium(VI) being readily reduced to chromium(III):

$$
\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+14 \mathrm{H}^{+}(a q)+6 \mathrm{e}^{-} \longrightarrow 2 \mathrm{Cr}^{3+}(a q)+7 \mathrm{H}_{2} \mathrm{O}(l) \quad E^{\circ}=1.33 \mathrm{~V}
$$

This reaction is often used to determine the iron content of a water or soil sample by oxidizing $\mathrm{Fe}^{2+}$ to $\mathrm{Fe}^{3+}$ ion. In basic solution, the $\mathrm{CrO}_{4}{ }^{2-}$ ion, which is a much weaker oxidizing agent, predominates:

$$
\mathrm{CrO}_{4}{ }^{2-}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l)+3 \mathrm{e}^{-} \longrightarrow \mathrm{Cr}(\mathrm{OH})_{3}(s)+5 \mathrm{OH}^{-}(a q) \quad E^{\circ}=-0.13 \mathrm{~V}
$$

The Concept of Valence-State Electronegativity Why does oxide acidity increase with oxidation state? And how can a metal, like chromium, form an oxoanion? To answer such questions, we must apply the concept of electronegativity to the various oxidation states of an element. A metal in a higher oxidation state is more positively charged, which increases its attraction for electrons; in effect, its electronegativity increases. This effective electronegativity, called valence-state electronegativity, also has numerical values. The electronegativity of chromium metal is 1.6 , close to that of aluminum (1.5), another active metal. For chromium(III), the value increases to 1.7 , still characteristic of a metal. However, the electronegativity of chromium(VI) is 2.3 , close to the values of some nonmetals, such as phosphorus (2.1), selenium (2.4), and carbon (2.5). Thus, like P in $\mathrm{PO}_{4}{ }^{3-}, \mathrm{Cr}$ in chromium(VI) compounds often occurs covalently bonded at the center of the oxoanion of a relatively strong acid.

## Manganese

Elemental manganese is hard and shiny and, like vanadium and chromium, is used mostly to make steel alloys. A small amount of $\mathrm{Mn}(<1 \%)$ makes steel easier to roll, forge, and weld. Steel made with $12 \% \mathrm{Mn}$ is tough enough to be used for naval armor, front-end loader buckets (see photo), and other extremely hard steel objects. Small amounts of manganese are added to aluminum beverage cans and bronze alloys to make them stiffer and tougher as well.

The chemistry of manganese resembled that $\Phi$ chpmi的rinseme respects. The free metal is quite reactive and readily reduces $\mathrm{H}^{+}$from acids, forming the pale-pink $\mathrm{Mn}^{2+}$ ion:

$$
\mathrm{Mn}(s)+2 \mathrm{H}^{+}(a q) \longrightarrow \mathrm{Mn}^{2+}(a q)+\mathrm{H}_{2}(g) \quad E^{\circ}=1.18 \mathrm{~V}
$$

Like chromium, manganese can use all its valence electrons in its compounds, exhibiting every possible positive oxidation state, with the $+2,+4$, and +7 states most common (Table 23.5). As the oxidation state of manganese rises, its valencestate electronegativity increases and its oxides change from basic to acidic. Manganese(II) oxide (MnO) is basic, and manganese(III) oxide $\left(\mathrm{Mn}_{2} \mathrm{O}_{3}\right)$ is amphoteric. Manganese(IV) oxide $\left(\mathrm{MnO}_{2}\right)$ is insoluble and shows no acid-base properties. [It is used in dry cells and alkaline batteries as the oxidizing agent in a redox reaction with zinc (Chapter 21, p. 952).] Manganese(VII) oxide ( $\mathrm{Mn}_{2} \mathrm{O}_{7}$ ),

Table 23.5 Some Oxidation States of Manganese

[^35]

Front-end loader buckets are made of steel containing manganese.

Sharing the Ocean's Wealth At their current rate of usage, known reserves of many key transition metals will be depleted in less than 50 years. Other sources must be found. One promising source is nodules strewn over large portions of the ocean floor. Varying from a few millimeters to a few meters in diameter, these chunks consist mainly of manganese and iron oxides, with oxides of other elements present in smaller amounts. Billions of tons exist, but mining them presents major technical and political challenges. Global agreements have designated the ocean floor as international property, so cooperation will be required to mine the nodules and share the mineral rewards.
which forms by reaction of Mn with pure $\mathrm{O}_{2}$, reacts with water to form permanganic acid $\left(\mathrm{HMnO}_{4}\right)$, which is as strong as perchloric acid $\left(\mathrm{HClO}_{4}\right)$.

All manganese species with oxidation states greater than +2 act as oxidizing agents, but the purple permanganate $\left(\mathrm{MnO}_{4}{ }^{-}\right)$ion is particularly powerful. Like ions with chromium in its highest oxidation state, $\mathrm{MnO}_{4}{ }^{-}$is a much stronger oxidizing agent in acidic than in basic solution:

$$
\begin{array}{ll}
\mathrm{MnO}_{4}^{-}(a q)+4 \mathrm{H}^{+}(a q)+3 \mathrm{e}^{-} \longrightarrow \mathrm{MnO}_{2}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) & E^{\circ}=1.68 \mathrm{~V} \\
\mathrm{MnO}_{4}^{-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)+3 \mathrm{e}^{-} \longrightarrow \mathrm{MnO}_{2}(s)+4 \mathrm{OH}^{-}(a q) & E^{\circ}=0.59 \mathrm{~V}
\end{array}
$$

Unlike $\mathrm{Cr}^{2+}$ and $\mathrm{Fe}^{2+}$, the $\mathrm{Mn}^{2+}$ ion resists oxidation in air. The $\mathrm{Cr}^{2+}$ ion is a $d^{4}$ species and readily loses a $3 d$ electron to form the $d^{3}$ ion $\mathrm{Cr}^{3+}$, which is more stable. The $\mathrm{Fe}^{2+}$ ion is a $d^{6}$ species, and removing a $3 d$ electron yields the stable, half-filled $d^{5}$ configuration of $\mathrm{Fe}^{3+}$. Removing an electron from $\mathrm{Mn}^{2+}$ disrupts its stable $d^{5}$ configuration.

## Silver

Silver, the second member of the coinage metals [Group 1B(11)], has been admired for thousands of years and is still treasured for use in jewelry and fine flatware. Because the pure metal is too soft for these purposes, however, it is alloyed with copper to form the harder sterling silver. In former times, silver was used in coins, but it has been replaced almost universally by copper-nickel alloys. Silver has the highest electrical conductivity of any element but is not used in wiring because copper is cheaper and more plentiful. In the past, silver was found in nuggets and veins of rock, often mixed with gold, because both elements are chemically inert enough to exist uncombined. Nearly all of those deposits have been mined, so most silver is now obtained from the anode mud formed during the electrorefining of copper (Section 22.4).
AThe bix important oxidation statecsilver is +1 . Its most important soluble compound is silver nitrate, used for electroplating and in the manufacture of the halides used for photographic film. Although silver forms no oxide in air, it tarnishes to black $\mathrm{Ag}_{2} \mathrm{~S}$ by reaction with traces of sulfur-containing compounds. Some polishes remove the $\mathrm{Ag}_{2} \mathrm{~S}$, along with some silver, by physically abrading the surface. An alternative "home remedy" that removes the tarnish and restores the metal involves heating the object in a solution of table salt or baking soda $\left(\mathrm{NaHCO}_{3}\right)$ in an aluminum pan. Aluminum, a strong reducing agent, reduces the $\mathrm{Ag}^{+}$ions back to the metal:

$$
2 \mathrm{Al}(s)+3 \mathrm{Ag}_{2} \mathrm{~S}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{Al}(\mathrm{OH})_{3}(s)+6 \mathrm{Ag}(s)+3 \mathrm{H}_{2} \mathrm{~S}(g) \quad E^{\circ}=0.86 \mathrm{~V}
$$

The Chemistry of Black-and-White Photography The most widespread use of silver compounds-particularly the three halides $\mathrm{AgCl}, \mathrm{AgBr}$, and AgI -is in black-and-white photography, an art that applies transition metal chemistry and solution kinetics. The photographic film itself is simply a flexible plastic support for the light-sensitive emulsion, which consists of AgBr microcrystals dispersed in gelatin. The five steps in obtaining a final photograph are exposing the film, developing the image, fixing the image, washing the negative, and printing the image. Figure 23.8 summarizes the first four of these steps. The process depends on several key chemical properties of silver and its compounds:

- Silver halides undergo a redox reaction when exposed to visible light.
- Silver chloride, bromide, and iodide are not water soluble.
- $\mathrm{Ag}^{+}$is easily reduced: $\mathrm{Ag}^{+}(a q)+\mathrm{e}^{-} \longrightarrow \mathrm{Ag}(s) ; E^{\circ}=0.80 \mathrm{~V}$.
- $\mathrm{Ag}^{+}$forms several stable, water-soluble complex ions.

1. Exposing the film. Light reflected from the objects in a scene-more light from bright objects than from dark ones-enters the camera lens and strikes the film. Exposed AgBr crystals absorb photons ( $h v$ ) in a very localized redox reac-

tion. $\mathrm{A} \mathrm{Br}^{-}$ion is excited by a photon and oxidized and the released electron
almost immediately reduces a nearby $\mathrm{Ag} \dot{\mathrm{Con}}$.

$$
\begin{array}{r}
\mathrm{Br}^{-} \xrightarrow{h \nu} \mathrm{Br}+\mathrm{e}^{-} \\
\mathrm{Ag}^{+}+e^{-} \longrightarrow \mathrm{Ag} \\
\mathrm{Ag}^{+}+\mathrm{Br}^{-} \xrightarrow{h \nu} \mathrm{Ag}+\mathrm{Br}
\end{array}
$$

Wherever more light strikes a microcrystal, more Ag atoms form. The exposed crystals are called a latent image because the few scattered atoms of photoreduced Ag are not yet visible. Nevertheless, their presence as crystal defects within the AgBr crystal makes it highly susceptible to further reduction.
2. Developing the image. The latent image is developed into the actual image by reducing more of the silver ions in the crystal in a controlled manner. Developing is a rate-dependent step: crystals with many photoreduced Ag atoms react more quickly than those with only a few. The developer is a weak reducing agent, such as the organic substance hydroquinone $\left(\mathrm{H}_{2} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{O}_{2} ; \mathrm{H}_{2} \mathrm{Q}\right)$ (see margin):
$2 \mathrm{Ag}^{+}(s)+\mathrm{H}_{2} \mathrm{Q}(a q$; reduced form $) \longrightarrow 2 \mathrm{Ag}(s)+\mathrm{Q}(a q$; oxidized form $)+2 \mathrm{H}^{+}(a q)$ The reaction rate depends on $\mathrm{H}_{2} \mathrm{Q}$ concentration, solution temperature, and the length of time the emulsion is bathed in the solution. After developing, approximately $10^{6}$ as many Ag atoms are present on the film as there were in the latent image, and they form very small, black clusters of silver.
3. Fixing the image. After the image is developed, it must be "fixed"; that is, the reduction of $\mathrm{Ag}^{+}$must be stopped, or the entire film will blacken on exposure to more light. Fixing involves removing the remaining $\mathrm{Ag}^{+}$chemically by converting it to a soluble complex ion with sodium thiosulfate solution ("hypo"):

$$
\mathrm{AgBr}(s)+2 \mathrm{~S}_{2} \mathrm{O}_{3}{ }^{2-}(a q) \longrightarrow \mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}(a q)+\mathrm{Br}^{-}(a q)
$$

4. Washing the negative. The water-soluble ions are washed away in water. Washing is the final step in producing a photographic negative, in which dark objects in the scene appear bright in the image, and vice versa.

5. Printing the image. Through the use of an enlarger, the image on the negative is projected onto print paper coated with emulsion (silver halide in gelatin) and exposed to light, and the previous chemical steps are repeated to produce a "positive" of the image. Bright areas on a negative, such as car tires, allow a great deal of light to pass through and reduce many $\mathrm{Ag}^{+}$ions on the print paper. Dark areas on a negative, such as clouds, allow much less light to pass through and, thus, much less $\mathrm{Ag}^{+}$reduction. Print-paper emulsion usually contains silver chloride, which reacts more slowly than silver bromide, giving finer control of the print image. High-speed film incorporates silver iodide, the most light-sensitive of the three halides.

## Mercury

Mercury has been known since ancient times because cinnabar $(\mathrm{HgS})$, its principal ore, is a naturally occurring red pigment (vermilion) that readily undergoes a redox reaction in the heat of a fire. Sulfide ion, the reducing agent for the process, is already present as part of the ore:

$$
\mathrm{HgS}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{Hg}(g)+\mathrm{SO}_{2}(g)
$$

The gaseous Hg condenses on cool nearby surfaces.
The Latin name hydrargyrum ("liquid silver") is a good description of mercury, the only metal that is liquid at room temperature. Two factors account for this unusual property. First, because of a distorted crystal structure, each mercury atom is surrounded by 6 rather than 12 nearest neighbors. Second, a filled, tightly held $d$ sublevel leaves only the two $6 s$ electrons available for metallic bonding. Thus, interactions among mercury atoms are relatively few and relatively weak and, as a result, the solid form breaks down at $-38.9^{\circ} \mathrm{C}$.

Many of mercury's uses arise from its unusual physical properties. Its liquid range ล39C to $357^{\circ}{ }^{\circ}$ ) enconpasse §nossereryday temperatures, so Hg is commonly used in thermometers. As you might expect from its position in Period 6 following the lanthanide contraction, mercury is quite dense $(13.5 \mathrm{~g} / \mathrm{mL})$, which makes it convenient for use in barometers and manometers. Mercury's fluidity and conductivity make it useful for "silent" switches in thermostats. At high pressures, mercury vapor can be excited electrically to emit the bright white light seen in sports stadium and highway lights.

Mercury is a good solvent for other metals, and many amalgams (alloys of mercury) exist. In mercury batteries, a zinc amalgam acts as the anode and mercury(II) oxide acts as the cathode (Chapter 21, p. 953). In the mercury-cell version of the chlor-alkali process (Chapter 22, p. 1015), mercury acts as the cathode and as the solvent for the sodium metal that forms. Recall that, when treated with water, the resulting sodium amalgam, $\mathrm{Na}(\mathrm{Hg})$, forms two important byproducts:

$$
2 \mathrm{Na}(\mathrm{Hg})+2 \mathrm{H}_{2} \mathrm{O}(l) \xrightarrow{-\mathrm{Hg}} 2 \mathrm{NaOH}(a q)+\mathrm{H}_{2}(g)
$$

The mercury is released in this step and reused in the electrolytic cell. In view of mercury's toxicity, which we discuss shortly, a newer method involving a polymeric membrane is replacing the mercury-cell method. Nevertheless, past contamination of wastewater from the chlor-alkali process and the disposal of old mercury batteries remain serious environmental concerns.

The chemical properties of mercury are unique within Group $2 \mathrm{~B}(12)$. The other members, zinc and cadmium, occur in the +2 oxidation state as $d^{10}$ ions, but mercury occurs in the +1 state as well, with the condensed electron configuration [Xe] $6 s^{1} 4 f^{14} 5 d^{10}$. We can picture the unpaired $6 s$ electron allowing two $\mathrm{Hg}(\mathrm{I})$ species to form the diatomic ion $[\mathrm{Hg}-\mathrm{Hg}]^{2+}$ (written $\mathrm{Hg}_{2}{ }^{2+}$ ), one of the
first species known with a covalent metal-metal bond (but also see the footnote on p. 1028). Mercury's more common oxidation state is +2 . Whereas $\mathrm{HgF}_{2}$ is largely ionic, many other compounds, such as $\mathrm{HgCl}_{2}$, contain bonds that are predominantly covalent. Most mercury(II) compounds are insoluble in water.

The common ions $\mathrm{Zn}^{2+}, \mathrm{Cd}^{2+}$, and $\mathrm{Hg}^{2+}$ are biopoisons. Zinc oxide is used as an external antiseptic ointment. The $\mathrm{Cd}^{2+}$ and $\mathrm{Hg}^{2+}$ ions are two of the socalled toxic heavy-metal ions. The cadmium in solder may be more responsible than the lead for solder's high toxicity. Mercury compounds have been used in agriculture as fungicides and pesticides and in medicine as internal drugs, but these uses have been largely phased out.

Because most mercury(II) compounds are insoluble in water, they were once thought to be harmless in the environment; but we now know otherwise. Microorganisms in sludge and river sediment convert mercury atoms and ions to the methyl mercury ion, $\mathrm{CH}_{3}-\mathrm{Hg}^{+}$, and then to organomercury compounds, such as dimethylmercury, $\mathrm{CH}_{3}-\mathrm{Hg}-\mathrm{CH}_{3}$. These toxic compounds are nonpolar and, like chlorinated hydrocarbons, become increasingly concentrated in fatty tissues, as they move up a food chain from microorganisms to worms to fish and, finally, to birds and mammals. Indeed, fish living in a mercury-polluted lake or coastal estuary can have a mercury concentration thousands of times higher than that of the water itself.

The mechanism for the toxicity of mercury and other heavy-metal ions is not fully understood. It is thought that the ions migrate from fatty tissue and bind strongly to thiol (-SH) groups of amino acids in proteins, thereby disrupting the proteins' structure and function. Because the brain has a high fat content, small amounts of lead, cadmium, and mercury ions circulating in the blood become deposited in the brain's fatty tissue, interact with its proteins, and often cause devastating neurological and psychological effects.

## Section Summary

Chromium and manganese add corrosion resistance and hardness to steels. They are typical of transition metals in having several oxidation states. - Valence-state electronegativity refers to the ability of an element in its various oxidation states to attract bonding electrons. It increases with oxidation number, which is the reason elements act more metallic (more ionic compounds, more basic oxides) in lower states and more nonmetallic (more acidic oxides, oxoanions of acids) in higher states. - Cr and Mn produce $\mathrm{H}_{2}$ in acid. $\mathrm{Cr}(\mathrm{VI})$ undergoes a pH -sensitive dehydration-condensation reaction. Both $\mathrm{Cr}(\mathrm{VI})$ and $\mathrm{Mn}(\mathrm{VII})$ are stronger oxidizing agents in acid than in base. • The only important oxidation state for silver is +1 . The silver halides are light sensitive and are used in photography. - Mercury, the only metal that is liquid at room temperature, dissolves many other metals in important applications. The mercury(l) ion is diatomic and has a metal-metal covalent bond. The element and its compounds are toxic and become concentrated as they move up a food chain.

### 23.4 COORDINATION COMPOUNDS

The most distinctive aspect of transition metal chemistry is the formation of coordination compounds (also called complexes). These are substances that contain at least one complex ion, a species consisting of a central metal cation (either a transition metal or a main-group metal) that is bonded to molecules and/or anions called ligands. In order to maintain charge neutrality in the coordination compound, the complex ion is typically associated with other ions, called counter ions.

Mad as a Hatter The felt top hat and zany manner of the Mad Hatter in Alice in Wonderland are literary references to the toxicity of mercury compounds. Mercury(II) nitrate and chloride were used with $\mathrm{HNO}_{3}$ to make felt for hats from animal hair. Inhalation of the dust generated by the process led to "hatter's shakes," abnormal behavior, and other neurological and psychological symptoms.

Figure 23.9 Components of a coordination compound. Coordination compounds, shown here as models (top), wedge-bond perspective drawings (middle), and chemical formulas (bottom), typically consist of a complex ion and counter ions to neutralize the charge. The complex ion has a central metal ion surrounded by ligands. A, When solid $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}$ dissolves in water, the complex ion and the counter ions separate, but the ligands remain bound to the metal ion. Six ligands around the metal ion give the complex ion an octahedral geometry. B, Complex ions with a central $d^{8}$ metal ion have four ligands and a square planar geometry.

A typical coordination compound appears in Figure 23.9A: the coordination compound is $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}$, the complex ion (always enclosed in square brackets) is $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$, the six $\mathrm{NH}_{3}$ molecules bonded to the central $\mathrm{Co}^{3+}$ are ligands, and the three $\mathrm{Cl}^{-}$ions are counter ions. A coordination compound behaves like an electrolyte in water: the complex ion and counter ions separate from each other. But the complex, ion behaves like a polyatomic ion: the ligands and centrat meta On remain attached. Phus, as Figure 23.9A shows, 1 mol of $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}$ yields 1 mol of $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ ions and 3 mol of $\mathrm{Cl}^{-}$ions.

We discussed the Lewis acid-base properties of hydrated metal ions, which are a type of complex ion, in Section 18.9, and we examined complex-ion equilibria in Section 19.4. In this section, we consider the bonding, structure, and properties of complex ions.

## Complex Ions: Coordination Numbers, Geometries, and Ligands

A complex ion is described by the metal ion and the number and types of ligands attached to it. Its structure is related to three characteristics-coordination number, geometry, and number of donor atoms per ligand:

- Coordination number. The coordination number is the number of ligand atoms that are bonded directly to the central metal ion and is specific for a given metal ion in a particular oxidation state and compound. The coordination number of the $\mathrm{Co}^{3+}$ ion in $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ is 6 because six ligand atoms $\left(\mathrm{N}\right.$ of $\left.\mathrm{NH}_{3}\right)$ are bonded to it. The coordination number of the $\mathrm{Pt}^{2+}$ ion in many of its complexes is 4 , whereas that of the $\mathrm{Pt}^{4+}$ ion in its complexes is 6. Copper(II) may have a coordination number of 2 , 4 , or 6 in different complex ions. In general, the most common coordination number in complex ions is 6 , but 2 and 4 are often seen, and some higher ones are also known.
- Geometry. The geometry (shape) of a complex ion depends on the coordination number and nature of the metal ion. Table 23.6 shows the geometries associated with the coordination numbers 2,4 , and 6 , with some examples of each. A complex ion whose metal ion has a coordination number of 2 , such as $\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}\right]^{+}$, is linear. The coordination number 4 gives rise to either of two geometries-square planar or tetrahedral. Most $d^{8}$ metal ions form square planar complex ions, depicted in Figure 23.9B. The $d^{10}$ ions are among those that

## Table 23.6 Coordination Numbers and Shapes of Some Complex Ions

| Coordination <br> Number | Shape | Examples |
| :---: | :--- | :--- |
| 2 | Linear | $\left[\mathrm{CuCl}_{2}\right]^{-},\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}\right]^{+},\left[\mathrm{AuCl}_{2}\right]^{-}$ <br> 4 |

form tetrahedral complex ions. A coordination number of 6 results in an octahedral geometry, as shown by $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ in Figure 23.9A. Note the similarity with some of the molecular shapes in VSEPR theory (Section 10.2).

- Donor atoms per ligand. The ligands of complex ions are molecules or anions with one or more donor atoms that each donate a lone pair of electrons to the metal ion to form a covalent bond. Because they have at least one lone pair,

Ligands are classified in terms of the number of donor atoms, or "teeth," that each uses to bond to the central metal ion. Monodentate (Latin, "one-toothed") ligands, such as $\mathrm{Cl}^{-}$and $\mathrm{NH}_{3}$, use a single donor atom. Bidentate ligands have two donor atoms, each of which bonds to the metal ion. Polydentate ligands have more than two donor atoms. Table 23.7 shows some common ligands in coordination compounds; note that each ligand has one or more donor atoms (colored type), each with a lone pair of electrons to donate. Bidentate and polydentate

Table 23.7 Some Common Ligands in Coordination Compounds

| Ligand Type | Examples |  |
| :---: | :---: | :---: |
| Monodentate | $\mathrm{H}_{2} \ddot{\mathrm{O}}:$ water $: \ddot{\mathrm{E}}:^{-}$ fluoride ion <br> $: \mathrm{NH}_{3}$ ammonia $: \ddot{\mathrm{C}}:^{-}$ chloride ion <br>   $[: \mathrm{C} \equiv \mathrm{N}:]^{-}$ <br>   $[\because \mathrm{S}=\mathrm{C}=\ddot{\mathrm{N}}:]^{-}$ <br> L or -   | cyanide ion hydroxide ion thiocyanate ion nitrite ion |
| Bidentate |  |  |
| Polydentate | ethylenediamine (en) <br> oxalate ion |  <br> ethylenediaminetetraacetate ion (EDTA ${ }^{4-}$ ) |

Grabbing lons Because it has 6 donor atoms, the ethylenediaminetetraacetate (EDTA ${ }^{4-}$ ) ion forms very stable complexes with many metal ions. This property makes EDTA useful in treating heavy-metal poisoning. Once ingested by the patient, the ion acts as a scavenger to remove lead and other heavy-metal ions from the blood and other body fluids.
ligands give rise to rings in the complex ion. For instance, ethylenediamine (abbreviated en in formulas) has a chain of four atoms (:N-C-C-N:), so it forms a five-membered ring, with the two electron-donating N atoms bonding to the metal atom. Such ligands seem to grab the metal ion like claws, so a complex ion that contains them is also called a chelate (pronounced "KEY-late"; Greek chela, "crab's claw").

## Formulas and Names of Coordination Compounds

There are three important rules for writing the formulas of coordination compounds, the first two being the same for writing formulas of any ionic compound:

1. The cation is written before the anion.
2. The charge of the cation(s) is balanced by the charge of the anion(s).
3. In the complex ion, neutral ligands are written before anionic ligands, and the formula for the whole ion is placed in brackets.

Let's apply these rules as we examine the combinations of ions in coordination compounds. The whole complex ion may be a cation or an anion. A complex cation has anionic counter ions, and a complex anion has cationic counter ions. It's easy to find the charge of the central metal ion. For example, in $\mathrm{K}_{2}\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{4}\right]$, two $\mathrm{K}^{+}$counter ions balance the charge of the complex anion $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{4}\right]^{2-}$, which contains two $\mathrm{NH}_{3}$ molecules and four $\mathrm{Cl}^{-}$ions as ligands. The two $\mathrm{NH}_{3}$ are neutral, the four $\mathrm{Cl}^{-}$have a total charge of $4-$, and the entire complex ion has a charge of $2-$, so the central metal ion must be $\mathrm{Co}^{2+}$ :

$$
\begin{aligned}
\text { Charge of complex ion } & =\text { Charge of metal ion }+ \text { total charge of ligands } \\
2- & =\text { Charge of metal ion }+[(2 \times 0)+(4 \times 1-)]
\end{aligned}
$$

So, $\quad$ Charge of metal ion $=(2-)-(4-)=2+$
In the compund $\left.\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{C}_{2}\right]$ Ce, necomplex ion is $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$and one $\mathrm{Cl}^{-}$is the counter ion. The four $\mathrm{NH}_{3}$ ligands are neutral, the two $\mathrm{Cl}^{-}$ligands have a total charge of $2-$, and the complex cation has a charge of $1+$, so the central metal ion must be $\mathrm{Co}^{3+}$ [that is, $1+=(3+)+(2-)$ ]. Some coordination compounds have a complex cation and a complex anion, as in $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Br}\right]_{2}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]$. In this compound, the complex cation is $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Br}\right]^{2+}$, with $\mathrm{Co}^{3+}$, and the complex anion is $\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{4-}$, with $\mathrm{Fe}^{2+}$.

Coordination compounds were originally named after the person who first prepared them or from their color, and some of these common names are still used, but most coordination compounds are named systematically through a set of rules:

1. The cation is named before the anion. In naming $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}$, for example, we name the $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$ion before the $\mathrm{Cl}^{-}$ion. Thus, the name is

> tetraamminedichlorocobalt(III) chloride

The only space in the name appears between the cation and the anion.
2. Within the complex ion, the ligands are named, in alphabetical order, before the metal ion. Note that in the $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$ion of the compound named in rule 1 , the four $\mathrm{NH}_{3}$ and two $\mathrm{Cl}^{-}$are named before the $\mathrm{Co}^{3+}$.
3. Neutral ligands generally have the molecule name, but there are a few exceptions (Table 23.8). Anionic ligands drop the -ide and add -o after the root name; thus, the name fluoride for the $\mathrm{F}^{-}$ion becomes the ligand name fluoro. The two ligands in $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$are ammine $\left(\mathrm{NH}_{3}\right)$ and chloro $\left(\mathrm{Cl}^{-}\right)$with ammine coming before chloro alphabetically.
4. A numerical prefix indicates the number of ligands of a particular type. For example, tetraammine denotes four $\mathrm{NH}_{3}$, and dichloro denotes two $\mathrm{Cl}^{-}$. Other prefixes are tri-, penta-, and hexa-. These prefixes do not affect the alphabet-

Table 23.8 Names of Some Neutral and Anionic Ligands

|  | Neutral |  | Anionic |  |
| :--- | :--- | :--- | :--- | :--- |
|  | Name | Formula |  | Name |
| Aqua | $\mathrm{H}_{2} \mathrm{O}$ |  | Fluormula | $\mathrm{F}^{-}$ |
| Ammine | $\mathrm{NH}_{3}$ |  | Chloro | $\mathrm{Cl}^{-}$ |
| Carbonyl | CO |  | Bromo | $\mathrm{Br}^{-}$ |
| Nitrosyl | NO | Iodo | $\mathrm{I}^{-}$ |  |
|  |  | Hydroxo | $\mathrm{OH}^{-}$ |  |
|  |  | Cyano | $\mathrm{CN}^{-}$ |  |

ical order; thus, tetraammine comes before dichloro. Because some ligand names already contain a numerical prefix (such as ethylenediamine), we use bis (2), tris (3), or tetrakis (4) to indicate the number of such ligands, followed by the ligand name in parentheses. For example, a complex ion that has two ethylenediamine ligands has bis(ethylenediamine) in its name.
5. The oxidation state of the central metal ion is given by a Roman numeral (in parentheses) only if the metal ion can have more than one state, as in the compound named in rule 1.
6. If the complex ion is an anion, we drop the ending of the metal name and add -ate. Thus, the name for $\mathrm{K}\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right) \mathrm{Cl}_{5}\right]$ is
potassium amminepentachloroplatinate(IV)
(Note that there is one $\mathrm{K}^{+}$counter ion, so the complex anion has a charge of $1-$. The five $\mathrm{Cl}^{-}$ligands have a total charge of $5-$, so Pt must be in the +4 oxidation state.) For some metas weace the intion with theemeching, shown in Table 23.9. For example, the name for $\mathrm{Na}_{4}\left[\mathrm{FeBr}_{6}\right]$ is
sodium hexabromoferrate(II)

## SAMPLE PROBLEM 23.3 Writing Names and Formulas of Coordination Compounds

PROBLEM (a) What is the systematic name of $\mathrm{Na}_{3}\left[\mathrm{AlF}_{6}\right]$ ?
(b) What is the systematic name of $\left[\mathrm{Co}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right] \mathrm{NO}_{3}$ ?
(c) What is the formula of tetraamminebromochloroplatinum(IV) chloride?
(d) What is the formula of hexaamminecobalt(III) tetrachloroferrate(III)?

PLAN We use the rules that were presented above and refer to Tables 23.8 and 23.9.
SOLUTION (a) The complex ion is $\left[\mathrm{AlF}_{6}\right]^{3-}$. There are six (hexa-) $\mathrm{F}^{-}$ions (fluoro) as ligands, so we have hexafluoro. The complex ion is an anion, so the ending of the metal ion (aluminum) must be changed to -ate: hexafluoroaluminate. Aluminum has only the +3 oxidation state, so we do not use a Roman numeral. The positive counter ion is named first and separated from the anion by a space: sodium hexafluoroaluminate.
(b) Listed alphabetically, there are two $\mathrm{Cl}^{-}$(dichloro) and two en [bis(ethylenediamine)] as ligands. The complex ion is a cation, so the metal name is unchanged, but we specify its oxidation state because cobalt can have several. One $\mathrm{NO}_{3}{ }^{-}$balances the $1+$ cation charge: with $2-$ for two $\mathrm{Cl}^{-}$and 0 for two en, the metal must be cobalt(III). The word nitrate follows a space: dichlorobis(ethylenediamine)cobalt(III) nitrate.
(c) The central metal ion is written first, followed by the neutral ligands and then (in alphabetical order) by the negative ligands. Tetraammine is four $\mathrm{NH}_{3}$, bromo is one $\mathrm{Br}^{-}$, chloro is one $\mathrm{Cl}^{-}$, and platinate( $(\mathrm{IV})$ is $\mathrm{Pt}^{4+}$, so the complex ion is $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{BrCl}\right]^{2+}$. Its $2+$ charge is the sum of $4+$ for $\mathrm{Pt}^{4+}, 0$ for four $\mathrm{NH}_{3}, 1-$ for one $\mathrm{Br}^{-}$, and $1-$ for one $\mathrm{Cl}^{-}$. To balance the $2+$ charge, we need two $\mathrm{Cl}^{-}$counter ions: $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{BrCl}^{2} \mathrm{Cl}_{2}\right.$.

Table 23.9 Names of Some Metal Ions in Complex Anions

| Metal | Name in Anion |
| :--- | :--- |
| Iron | Ferrate |
| Copper | Cuprate |
| Lead | Plumbate |
| Silver | Argentate |
| Gold | Aurate |
| Tin | Stannate |

(d) This compound consists of two different complex ions. In the cation, hexaammine is six $\mathrm{NH}_{3}$ and cobalt(III) is $\mathrm{Co}^{3+}$, so the cation is $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$. The $3+$ charge is the sum of $3+$ for $\mathrm{Co}^{3+}$ and 0 for six $\mathrm{NH}_{3}$. In the anion, tetrachloro is four $\mathrm{Cl}^{-}$, and ferrate(III) is $\mathrm{Fe}^{3+}$, so the anion is $\left[\mathrm{FeCl}_{4}\right]^{-}$. The $1-$ charge is the sum of $3+$ for $\mathrm{Fe}^{3+}$ and $4-$ for four $\mathrm{Cl}^{-}$. In the neutral compound, one $3+$ cation is balanced by three $1-$ anions: $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]\left[\mathrm{FeCl}_{4}\right]_{3}$.
CHECK Reverse the process to be sure you obtain the name or formula asked for in the problem.
FOLLOW-UP PROBLEM 23.3 (a) What is the name of $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{Br}\right] \mathrm{Cl}_{2}$ ?
(b) What is the formula of barium hexacyanocobaltate(III)?

## A Historical Perspective: Alfred Werner and Coordination Theory

The substances we now call coordination compounds had been known for almost 200 years when the young Swiss chemist Alfred Werner began studying them in the 1890s. He investigated a series of compounds such as the cobalt series shown in Table 23.10, each of which contains one cobalt(III) ion, three chloride ions, and a given number of ammonia molecules. At the time, which was 30 years before the idea of atomic orbitals was proposed, no structural theory could explain how compounds with similar, even identical, formulas could have widely different properties.

Werner measured the conductivity of each compound in aqueous solution to determine the total number of ions that became dissociated. He treated the solutions with excess $\mathrm{AgNO}_{3}$ to precipitate released $\mathrm{Cl}^{-}$ions as AgCl and thus determine the number of free $\mathrm{Cl}^{-}$ions per formula unit. Previous studies had established that the $\mathrm{NH}_{B}$ molecules were not free in solution. Werner's data, sum-
 mulas of the compounds. Other chemists had proposed "chain" structures, like those of organic compounds, to explain such data. For example, a proposed structure for $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}$ was

However, these models proved inadequate.
Werner's novel idea was the coordination complex, a central metal ion surrounded by a constant total number of covalently bonded molecules and/or anions. The coordination complex could be neutral or charged; if charged, it combined with oppositely charged counter ions, in this case $\mathrm{Cl}^{-}$, to form the neutral compound.

Table 23.10 Some Coordination Compounds of Cobalt Studied by Werner

|  | Werner's Data* |  |  |  |  |
| :--- | :---: | :---: | :--- | :--- | :---: |
| Traditional <br> Formula | Total <br> lons | Free <br> Cl- |  | Modern <br> Formula | Charge of <br> Complex Ion |
| $\mathrm{CoCl}_{3} \cdot 6 \mathrm{NH}_{3}$ | 4 | 3 |  | $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}$ | $3+$ |
| $\mathrm{CoCl}_{3} \cdot 5 \mathrm{NH}_{3}$ | 3 | 2 |  | $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}^{-}\right] \mathrm{Cl}_{2}$ | $2+$ |
| $\mathrm{CoCl}_{3} \cdot 4 \mathrm{NH}_{3}$ | 2 | 1 | $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}$ | $1+$ |  |
| $\mathrm{CoCl}_{3} \cdot 3 \mathrm{NH}_{3}$ | 0 | 0 | $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Cl}_{3}\right]$ | - |  |

*Moles per mole of compound.

Werner proposed two types of valence, or combining ability, for metal ions. Primary valence, now called oxidation state, is the positive charge on the metal ion that must be satisfied by an equivalent negative charge. In Werner's cobalt series, the primary valence is +3 , and it is always balanced by three $\mathrm{Cl}^{-}$ions. These anions can be bonded covalently to Co as part of the complex ion and/or associated with it as counter ions. Secondary valence, now called coordination number, is the constant total number of connections (anionic or neutral ligands) within the complex ion. The secondary valence in this series of Co compounds is 6 .

As you can see, Werner's data are satisfied if the total number of ligands remains the same for each compound, even though the numbers of $\mathrm{Cl}^{-}$ions and $\mathrm{NH}_{3}$ molecules in the different complex ions vary. For example, the first compound, $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}$, has a total of four ions: one $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ and three $\mathrm{Cl}^{-}$. All three $\mathrm{Cl}^{-}$ions are free to form AgCl . The last compound, $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Cl}_{3}\right]$, contains no separate ions.

Surprisingly, Werner was an organic chemist, and his work on coordination compounds, which virtually revolutionized his contemporaries' understanding of chemical bonding, was his attempt to demonstrate the unity of chemistry. For these pioneering studies, especially his prediction of optical isomerism (discussed shortly), Werner received the Nobel Prize in chemistry in 1913.

## Isomerism in Coordination Compounds

Isomers are compounds with the same chemical formula but different properties. We discussed many aspects of isomerism in the context of organic compounds in Section 15.2; it may be helpful to review that section now. Figure 23.10 presents an overview of the most common types of isomerism in coordination compounds.

Figure 23.10 Important types of isomerism in coordination compounds.

ISOMERS
Same chemical formula, but different properties

Constitutional Isomers: Same Atoms Connected Differently Two compounds with the same formula, but with the atoms connected differently, are called constitutional (structural) isomers. Coordination compounds exhibit the following two types of constitutional isomers: one involves a difference in the composition of the complex ion, the other in the donor atom of the ligand.

1. Coordination isomers occur when the composition of the complex ion changes but not that of the compound. One way this type of isomerism occurs is when ligand and counter ion exchange positions, as in $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]\left(\mathrm{NO}_{2}\right)_{2}$ and $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{4}\left(\mathrm{NO}_{2}\right)_{2}\right] \mathrm{Cl}_{2}$. In the first compound, the $\mathrm{Cl}^{-}$ions are the ligands, and the $\mathrm{NO}_{2}{ }^{-}$ions are counter ions; in the second, the roles are reversed. Another way that this type of isomerism occurs is in compounds of two complex ions in which the two sets of ligands in one compound are reversed in the other, as in $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right]\left[\mathrm{Co}(\mathrm{CN})_{6}\right]$ and $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]\left[\mathrm{Cr}(\mathrm{CN})_{6}\right]$; note that $\mathrm{NH}_{3}$ is a ligand of $\mathrm{Cr}^{3+}$ in one compound and of $\mathrm{Co}^{3+}$ in the other.
2. Linkage isomers occur when the composition of the complex ion remains the same but the attachment of the ligand donor atom changes. Some ligands can bind to the metal ion through either of two donor atoms. For example, the nitrite ion can bind through a lone pair on either the N atom (nitro, $\mathrm{O}_{2} \mathrm{~N}$ :) or one of the O atoms (nitrito, ONO:) to give linkage isomers, as in the orange compound pentaamminenitrocobalt(III) chloride $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5}\left(\mathrm{NO}_{2}\right)\right] \mathrm{Cl}_{2}$ (below left) and its reddish linkage isomer pentaamminenitritocobalt(III) chloride $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5}(\mathrm{ONO})\right] \mathrm{Cl}_{2}$ (below right):

Nitro isomer, $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5}\left(\mathrm{NO}_{2}\right)\right] \mathrm{Cl}_{2}$

Nitrito isomer, $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5}(\mathrm{ONO})\right] \mathrm{Cl}_{2}$

Another example is the cyanate ion, which can attach via a lone pair on the O atom (cyanato, $\mathrm{NCO}:$ ) or the N atom (isocyanato, OCN :); the thiocyanate ion behaves similarly, attaching via the S atom or the N atom:

Stereoisomers: Different Spatial Arrangements of Atoms Stereoisomers are compounds that have the same atomic connections but different spatial arrangements of the atoms. The two types we discussed for organic compounds, called geometric and optical isomers, are seen with coordination compounds as well:

1. Geometric isomers (also called cis-trans isomers and, sometimes, diastereomers) occur when atoms or groups of atoms are arranged differently in space relative to the central metal ion. For example, the square planar $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\right]$ has two arrangements, which give rise to two different compounds (Figure 23.11A). The isomer with identical ligands next to each other is cisdiamminedichloroplatinum(II), and the one with identical ligands across from each other is trans-diamminedichloroplatinum(II); their biological behaviors are remarkably different. Octahedral complexes also exhibit cis-trans isomerism (Figure 23.11B). The cis isomer of the $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$ion has the two $\mathrm{Cl}^{-}$ligands next to each other and is violet, whereas the trans isomer has these two ligands across from each other and is green.
2. Optical isomers (also called enantiomers) occur when a molecule and its mirror image cannot be superimposed (see Figures 15.8 to 15.10 , pp. 639 and 640). Unlike other types of isomers, which have distinct physical properties, optical isomers are physically identical in all ways but one: the direction in which they rotate the plane of polarized light. Octahedral complex ions show many examples of optical isomerism, which we can observe by rotating one isomer and seeing if it is superimposable on the other isomer (its mirror image). For example, as you can see in Figure 23.12 A , the two structures (I and II) of $\left[\mathrm{Co}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right]^{+}$, the cis-dichlorobis(ethylenediamine)cobalt(III) ion, are mirror images of each other. Rotate structure I $180^{\circ}$ around a vertical axis, and you obtain III. The $\mathrm{Cl}^{-}$li-

isomerism. A, The cis and trans isomers of the square planar coordination compound $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\right]$. B, The cis and trans isomers of the octahedral complex ion $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right]^{+}$. The colored shapes represent the actual colors of the species.
gands of III match those of II, but the en ligands do not: II and III (rotated I) are not superimposable; therefore, they are optical isomers. One isomer is designated $d-\left[\mathrm{Co}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right]^{+}$and the other is $l-\left[\mathrm{Co}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right]^{+}$, depending on whether it rotates polarized light to the right ( $d$ - for "dextro-") or to the left ( $l$ - for "levo-"). (The $d$ - or $l$ - designation can only be determined experimentally, not by examination of the structure.) In contrast, as shown in Figure 23.12B, the two structures of the trans-dichlorobis(ethylenediamine)cobalt(III) ion are not optical isomers: rotate I $90^{\circ}$ around a vertical axis and you obtain III, which is superimposable on II.

SAMPLE PROBLEM 23.4 Determining the Type of Stereoisomerism
PROBLEM Draw all stereoisomers for each of the following and state the type of isomerism:
(a) $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Br}_{2}\right]$ (square planar)
(b) $\left[\mathrm{Cr}(\text { en })_{3}\right]^{3+}\left(\right.$ en $\left.=\mathrm{H}_{2} \ddot{\mathrm{~N} C H_{2}} \mathrm{CH}_{2} \mathrm{NH}_{2}\right)$

PLAN We first determine the geometry around each metal ion and the nature of the ligands. If there are two different ligands that can be placed in different positions relative to each other, geometric (cis-trans) isomerism occurs. Then, we see whether the mirror image of an isomer is superimposable on the original. If it is not, optical isomerism occurs.
SOLUTION (a) The $\mathrm{Pt}(\mathrm{II})$ complex is square planar, and there are two different monodentate ligands. Each pair of ligands can lie next to or across from each other (see structures in margin). Thus, geometric isomerism occurs. Each isomer is superimposable on its mirror image, so there is no optical isomerism.
(b) Ethylenediamine (en) is a bidentate ligand. $\mathrm{The}_{\mathrm{Cr}}{ }^{3+}$ has a coordination number of 6 and an octahedral geometry, like $\mathrm{Co}^{3+}$. The three bidentate ligands are identical, so there is no geometric isomerism. However, the complex ion has a nonsuperimposable mirror image (see structures in margin). Thus, optical isomerism occurs.
FOLLOW-UP PROBLEM 23.4 What stereoisomers, if any, are possible for the $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{2}(\mathrm{en}) \mathrm{Cl}_{2}\right]^{+}$ion?

## Section Summary

Coordination compounds consist of a complex ion and charge-balancing counter ions. The complex ion has a central metal ion bonded to neutral and/or anionic ligands, which have one or more donor atoms that each provide a lone pair of electrons. - The most common geometry is octahedral (six ligand atoms bonding). • Formulas and names of coordination compounds follow systematic rules. - Werner established the structural basis of coordination compounds. - These compounds can exhibit constitutional isomerism (coordination and linkage) and stereoisomerism (geometric and optical).

### 23.5 THEORETICAL BASIS FOR THE BONDING AND PROPERTIES OF COMPLEXES

In this section, we consider models that address, in different ways, several key features of complexes: how metal-ligand bonds form, why certain geometries are preferred, and why these complexes are brightly colored and often paramagnetic. As you saw with covalent bonding in other compounds (Chapter 11), more than one model is often needed to tell the whole story.

## Application of Valence Bond Theory to Complex Ions

Valence bond (VB) theory, which helped explain bonding and structure in maingroup compounds (Section 11.1), is also used to describe bonding in complex ions. In the formation of a complex ion, the filled ligand orbital overlaps the empty metal-ion orbital. The ligand (Lewis base) donates the electron pair, and the metal ion (Lewis acid) accepts it to form one of the covalent bonds of the complex ion (Lewis adduct) (Section 18.9). Such a bond, in which one atom in the bond contributes both electrons, is called a coordinate covalent bond, although, once formed, it is identical to any covalent single bond. Recall that the VB concept of hybridization proposes the mixing of particular combinations of $s$, $p$, and $d$ orbitals to give sets of hybrid orbitals, which have specific geometries. Similarly, for coordination compounds, the model proposes that the number and type of metal-ion hybrid orbitals occupied by ligand lone pairs determine the geometry of the complex ion. Let's discuss the orbital combinations that lead to octahedral, square planar, and tetrahedral geometries.

Octahedral Complexes The hexaamminechromium(III) ion, $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$, illustrates the application of VB theory to an octahedral complex (Figure 23.13). The six lowest energy empty orbitals of the $\mathrm{Cr}^{3+}$ ion-two $3 d$, one $4 s$, and three $4 p$ mix and become six equivalent $d^{2} s p^{3}$ hybrid orbitals that point toward the corners of an octahedron.* Six $\mathrm{NH}_{3}$ molecules donate lone pairs from their nitrogens to form six metal-ligand bonds. The three unpaired $3 d$ electrons of the central $\mathrm{Cr}^{3+}$ ion ([Ar] $3 d^{3}$ ), which make the complex ion paramagnetic, remain in unhybridized orbitals.
Square Planar Complexes Metal ions with a $d^{8}$ configuration usually form square planar complexes (Figure 23.14). In the $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ ion, for example, the model proposes that one $3 d$, one $4 s$, and two $4 p$ orbitals of $\mathrm{Ni}^{2+}$ mix and form four $d s p^{2}$ hybrid orbitals, which point to the corners of a square and accept one electron pair from each of four $\mathrm{CN}^{-}$ligands

A look at the ground-state electron coufguration or the Finhancer ion, hower, raises a key question: how can the $\mathrm{Ni}^{2+}$ ion ([Ar] $3 d^{8}$ ) offer an empty $3 d$ orbital for accepting a lone pair, if its eight $3 d$ electrons lie in three filled and two halffilled orbitals? Apparently, in the $d^{8}$ configuration of $\mathrm{Ni}^{2+}$, electrons in the halffilled orbitals pair up and leave one $3 d$ orbital empty. This explanation is consistent with the fact that the complex is diamagnetic (no unpaired electrons). Moreover, it requires that the energy gained by using a $3 d$ orbital for bonding in the hybrid orbital is greater than the energy required to overcome repulsions from pairing the $3 d$ electrons.

B, Mixing one 4 s and three $4 p$ orbitals gives four $s p^{3}$ hybrid orbitals available for accepting lone pairs (red) from $\mathrm{OH}^{-}$ligands.

Figure 23.16 An artist's wheel. Colors, with approximate wavelength ranges (in nm ), are shown as wedges. Complementary colors, such as red and green, lie opposite each other.

Tetrahedral Complexes Metal ions that have a filled $d$ sublevel, such as $\mathrm{Zn}^{2+}$ ([Ar] $3 d^{10}$ ), often form tetrahedral complexes (Figure 23.15). For the complex ion $\left[\mathrm{Zn}(\mathrm{OH})_{4}\right]^{2-}$, for example, VB theory proposes that the lowest available $\mathrm{Zn}^{2+}$ orbitals-one $4 s$ and three $4 p$-mix to become four $s p^{3}$ hybrid orbitals that point to the corners of a tetrahedron and are occupied by four lone pairs, one from each of four $\mathrm{OH}^{-}$ligands.

## Crystal Field Theory

The VB model is easy to picture and rationalizes bonding and shape, but it treats the orbitals as little more than empty "slots" for accepting electron pairs. Consequently, it gives no insight into the colors of coordination compounds and sometimes predicts their magnetic properties incorrectly. In contrast to the VB approach, crystal field theory provides little insight about metal-ligand bonding but explains color and magnetism clearly. To do so, it highlights the effects on the d-orbital energies of the metal ion as the ligands approach. Before we dis-

What Is Color? White light is electromagnetic radiation consisting of all wavelengths $(\lambda)$ in the visible range (Section 7.1). It can be dispersed into a spectrum of colors, each of which has a narrower range of wavelengths. Objects appear colored in white light because they absorb certain wavelengths and reflect or transmit others: an opaque object reflects light, whereas a clear one transmits it. The reflected or transmitted light enters the eye and the brain perceives a color. If an object absorbs all visible wavelengths, it appears black; if it reflects all, it appears white.

Each color has a complementary color. For example, green and red are complementary colors. A mixture of complementary colors absorbs all visible wavelengths and appears black. Figure 23.16 shows these relationships on an artist's color wheel, where complementary colors appear as wedges opposite each other.

An object has a particular color for one of two reasons:

- It reflects (or transmits) light of that color. Thus, if an object absorbs all wavelengths except green, the reflected (or transmitted) light enters our eyes and is interpreted as green.
- It absorbs light of the complementary color. Thus, if the object absorbs only red, the complement of green, the remaining mixture of reflected (or transmitted) wavelengths enters our eyes and is interpreted as green also.

Table 23.11 lists the color absorbed and the resulting color perceived. A familiar example of this phenomenon results in the seasonal colors of deciduous trees. In the spring and summer, leaves contain high concentrations of the photosynthetic pigment chlorophyll and lower concentrations of other pigments called xanthophylls. Chlorophyll absorbs strongly in the blue and red regions, reflecting mostly green wavelengths into your eyes. In the fall, photosynthesis slows, so the leaf no longer makes chlorophyll. Gradually, the green color fades as the chlorophyll decomposes, revealing the xanthophylls that were present all along but masked

Table 23.11 Relation Between Absorbed and Observed Colors

| Absorbed Color | $\boldsymbol{\lambda}(\mathrm{nm})$ | Observed Color | $\boldsymbol{\lambda}(\mathrm{nm})$ |
| :--- | :---: | :--- | :---: |
| Violet | 400 | Green-yellow | 560 |
| Blue | 450 | Yellow | 600 |
| Blue-green | 490 | Red | 620 |
| Yellow-green | 570 | Violet | 410 |
| Yellow | 580 | Dark blue | 430 |
| Orange | 600 | Blue | 450 |
| Red | 650 | Green | 520 |

by the chlorophyll. Xanthophylls absorb green and blue strongly, reflecting the bright yellows and reds of autumn (see photo).
Splitting of $\boldsymbol{d}$ Orbitals in an Octahedral Field of Ligands The crystal field model explains that the properties of complexes result from the splitting of $d$-orbital energies, which arises from electrostatic interactions between metal ion and ligands. The model assumes that a complex ion forms as a result of electrostatic attractions between the metal cation and the negative charge of the ligands. This negative charge is either partial, as in a polar neutral ligand like $\mathrm{NH}_{3}$, or full, as in an anionic ligand like $\mathrm{Cl}^{-}$. The ligands approach the metal ion along the mutually perpendicular $x, y$, and $z$ axes, which minimizes the overall energy of the system.

Picture what happens as the ligands approach. Figure 23.17A shows six ligands moving toward a metal ion to form an octahedral complex. Let's see how the various $d$ orbitals of the metal ion are affected as the complex forms. As the ligands approach, their electron pairs repel electrons in the five $d$ orbitals. In the isolated metal ion, the $d$ orbitals hateequil Cnergles despite madaifferntientations. In the electrostatic field of ligands, however, the $d$ electrons are repelled unequally because their orbitals have different orientations. Because the ligands move along the $x, y$, and $z$ axes, they approach directly toward the lobes of the $d_{x^{2}-y^{2}}$ and $d_{z^{2}}$ orbitals (Figure 23.17B and C) but between the lobes of the $d_{x y}$, $d_{x z}$, and $d_{y z}$ orbitals (Figure 23.17D to F). Thus, electrons in the $d_{x^{2}-y^{2}}$ and $d_{z^{2}}$ orbitals experience stronger repulsions than those in the $d_{x y}, d_{x z}$, and $d_{y z}$ orbitals.

Foliage changing color in autumn.

Figure 23.17 The five $d$ orbitals in an octahedral field of ligands. The direction of ligand approach influences the strength of repulsions of electrons in the five metal ion $d$ orbitals. A, We assume that ligands approach a metal ion along the three linear axes in an octahedral orientation. $\mathbf{B}$ and $\mathbf{C}$, Lobes of the $d_{x^{2}-y^{2}}$ and $d_{z^{2}}$ orbitals lie directly in line with the approaching ligands, so repulsions are stronger. $\mathbf{D}$ to $\mathbf{F}$, Lobes of the $d_{x y}, d_{x z}$, and $d_{y z}$ orbitals lie between the approaching ligands, so repulsions are weaker.

Figure 23.18 Splitting of d-orbital energies by an octahedral field of ligands. Electrons in the $d$ orbitals of the free metal ion experience an average net repulsion in the negative ligand field that increases all $d$-orbital energies. Electrons in the $d_{x y}, d_{y z}$, and $d_{x z}$ orbitals, which form the $t_{2 g}$ set, are repelled less than those in the $d_{x^{2}-y^{2}}$, and $d_{z^{2}}$ orbitals, which form the $e_{g}$ set. The energy difference between these two sets is the crystal field splitting energy, $\Delta$.

Figure 23.19 The effect of the ligand on splitting energy. Ligands interacting strongly with metal-ion $d$ orbitals, such as $\mathrm{CN}^{-}$, produce a larger $\Delta$ than those interacting weakly, such as $\mathrm{H}_{2} \mathrm{O}$.

An energy diagram of the orbitals shows that all five $d$ orbitals are higher in energy in the forming complex than in the free metal ion because of repulsions from the approaching ligands, but the orbital energies split, with two $d$ orbitals higher in energy than the other three (Figure 23.18). The two higher energy orbitals are called $\boldsymbol{e}_{\boldsymbol{g}}$ orbitals, and the three lower energy ones are $\boldsymbol{t}_{\mathbf{2 g}}$ orbitals. (These designations refer to features of the orbitals that need not concern us here.)

The splitting of orbital energies is called the crystal field effect, and the difference in energy between the $e_{g}$ and $t_{2 g}$ sets of orbitals is the crystal field splitting energy ( $\Delta$ ). Different ligands create crystal fields of different strength and, thus, cause the $d$-orbital energies to split to different extents. Strong-field ligands lead to a larger splitting energy (larger $\Delta$ ); weak-field ligands lead to a smaller splitting energy (smaller $\Delta$ ). For instance, $\mathrm{H}_{2} \mathrm{O}$ is a weak-field ligand, and $\mathrm{CN}^{-}$ is a strong-field ligand (Figure 23.19). The magnitude of $\Delta$ relates directly to the cotor and inagnetic properties of acomplex.
Explaining the Colors of Transition Metals The remarkably diverse colors of coordination compounds are determined by the energy difference ( $\Delta$ ) between the $t_{2 g}$ and $e_{g}$ orbital sets in their complex ions. When the ion absorbs light in the visible range, electrons are excited ("jump") from the lower energy $t_{2 g}$ level to the higher $e_{g}$ level. Recall that the difference between two electronic energy levels in the ion is equal to the energy (and inversely related to the wavelength) of the absorbed photon:

$$
\Delta E_{\text {electron }}=E_{\text {photon }}=h \nu=h c / \lambda
$$

The substance has a color because only certain wavelengths of the incoming white light are absorbed.

Consider the $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ ion, which appears purple in aqueous solution (Figure 23.20). Hydrated $\mathrm{Ti}^{3+}$ is a $d^{1}$ ion, with the $d$ electron in one of the three

Figure 23.20 The color of $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$. A , The hydrated $\mathrm{Ti}^{3+}$ ion is purple in aqueous solution. $\mathbf{B}, \mathrm{An}$ absorption spectrum shows that incoming wavelengths corresponding to green and yellow light are

absorbed, whereas other wavelengths are transmitted. C, An orbital diagram depicts the colors absorbed in the excitation of the $d$ electron to the higher level.
lower energy $t_{2 g}$ orbitals. The energy difference ( $\Delta$ ) between the $t_{2 g}$ and $e_{g}$ orbitals in this ion corresponds to the energy of photons spanning the green and yellow range. When white light shines on the solution, these colors of light are absorbed, and the electron jumps to one of the $e_{g}$ orbitals. Red, blue, and violet light are transmitted, so the solution appears purple.

Absorption spectra show the wavelengths absorbed by a given metal ion with different ligands and by different metal ions with the same ligand. From such data, we relate the energy of the absorbed light to the $\Delta$ values, and two important observations emerge:

1. For a given ligand, the color depends on the oxidation state of the metal ion. A solution of $\left[\mathrm{V}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ ion is violet, and a solution of $\left[\mathrm{V}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ ion is yellow (Figure 23.21A).
2. For a given metal ion, the color depends on the ligand. Even a single ligand substitution can have a major effect on the wavelengths absorbed and, thus, the color, as you can see for two $\mathrm{Cr}^{3+}$ complex ions in Figure 23.21B.

The second observation allows us to rank ligands into a spectrochemical series with regard to their ability to split $d$-orbital energies. An abbreviated series, moving from weak-field ligands (small splitting, small $\Delta$ ) to strong-field ligands (large splitting, large $\Delta$ ), is shown in Figure 23.22. Using this series, we can predict the relative size of $\Delta$ for a series of octahedral complexes of the same metal ion. Although it is difficult to predict the actual color of a given complex, we can determine whether a complex will absorb longer or shorter wavelengths than other complexes in the series.

## SAMPLE PROBLEM 23.5 Ranking Crystal Field Splitting Energies for Complex Ions of a Given Metal

PROBLEM Rank the ions $\left[\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+},\left[\mathrm{Ti}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$, and $\left[\mathrm{Ti}(\mathrm{CN})_{6}\right]^{3-}$ in terms of the relative value of $\Delta$ and of the energy of visible light absorbed.
PLAN The formulas show that titanium's oxidation state is +3 in the three ions. From Figure 23.22, we rank the ligands in terms of crystal field strength: the stronger the ligand, the greater the splitting, and the higher the energy of light absorbed.
SOLUTION The ligand field strength is in the order $\mathrm{CN}^{-}>\mathrm{NH}_{3}>\mathrm{H}_{2} \mathrm{O}$, so the relative size of $\Delta$ and energy of light absorbed is

$$
\mathrm{Ti}(\mathrm{CN})_{6}{ }^{3-}>\mathrm{Ti}\left(\mathrm{NH}_{3}\right)_{6}{ }^{3+}>\mathrm{Ti}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}
$$

FOLLOW-UP PROBLEM 23.5 Which complex ion absorbs visible light of higher energy, $\left[\mathrm{V}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ or $\left[\mathrm{V}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ ?

Figure 23.22 The spectrochemical series. As the crystal field strength of the ligand increases, the splitting energy ( $\Delta$ ) increases, so shorter wavelengths $(\lambda)$ of light must be absorbed to excite electrons. Water is usually a weak-field ligand.

Figure 23.21 Effects of the metal oxidation state and of ligand identity on color. A, Solutions of $\left[\mathrm{V}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ (left) and $\left[\mathrm{V}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ (right) ions have different colors. B, A change in even a single ligand can influence the color. The $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ ion is yellow-orange (left); the $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right]^{2+}$ ion is purple (right).

Figure 23.24 Orbital occupancy for high-spin and low-spin complexes of $d^{4}$ through $d^{7}$ metal ions.

Figure 23.23 High-spin and low-spin complex ions of $\mathrm{Mn}^{2+}$. A , The free $\mathrm{Mn}^{2+}$ ion has five unpaired electrons. B, Bonded to weak-field ligands (smaller $\Delta$ ), $\mathrm{Mn}^{2+}$ still has five unpaired electrons (high-spin complex). C, Bonded to strong-field ligands (larger $\Delta$ ), $\mathrm{Mn}^{2+}$ has only one unpaired electron (low-spin complex).

Explaining the Magnetic Properties of Transition Metal Complexes The splitting of energy levels influences magnetic properties by affecting the number of unpaired electrons in the metal ion's $d$ orbitals. Based on Hund's rule, electrons occupy orbitals one at a time as long as orbitals of equal energy are available. When all lower energy orbitals are half-filled, the next electron can

- enter a half-filled orbital and pair up by overcoming a repulsive pairing energy ( $E_{\text {pairing }}$ ), or
- enter an empty, higher energy orbital by overcoming the crystal field splitting energy ( $\Delta$ ).
Thus, the relative sizes of $E_{p a i r i n g}$ and $\Delta$ determine the occupancy of the d orbitals. The grbital gccupacy $y_{2}$ pattern in turn, determines the number of unpaired electrons and, thus, the paramagnetic behavior of the ion.

As an example, the isolated $\mathrm{Mn}^{2+}$ ion ( $[\mathrm{Ar}] 3 d^{5}$ ) has five unpaired electrons in $3 d$ orbitals of equal energy (Figure 23.23A). In an octahedral field of ligands, the orbital energies split. The orbital occupancy is affected by the ligand in one of two ways:

- Weak-field ligands and high-spin complexes. Weak-field ligands, such as $\mathrm{H}_{2} \mathrm{O}$ in $\left[\mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$, cause a small splitting energy, so it takes less energy for $d$ electrons to jump to the $e_{g}$ set than to pair up in the $t_{2 g}$ set. Therefore, the $d$ electrons remain unpaired (Figure 23.23B). Thus, with weak-field ligands, the pairing energy is greater than the splitting energy $\left(E_{\text {pairing }}>\Delta\right)$; therefore, the number of unpaired electrons in the complex ion is the same as in the free ion. Weak-field ligands create high-spin complexes, those with the maximum number of unpaired electrons.
- Strong-field ligands and low-spin complexes. In contrast, strong-field ligands, such as $\mathrm{CN}^{-}$in $\left[\mathrm{Mn}(\mathrm{CN})_{6}\right]^{4-}$, cause a large splitting of the $d$-orbital energies, so it takes more energy for electrons to jump to the $e_{g}$ set than to pair up in the $t_{2 g}$ set (Figure 23.23C). With strong-field ligands, the pairing energy is smaller than the splitting energy ( $E_{\text {pairing }}<\Delta$ ); therefore, the number of unpaired electrons in the complex ion is less than in the free ion. Strong-field ligands create low-spin complexes, those with fewer unpaired electrons.
Orbital diagrams for the $d^{1}$ through $d^{9}$ ions in octahedral complexes show that both high-spin and low-spin options are possible only for $d^{4}, d^{5}, d^{6}$, and $d^{7}$ ions (Figure 23.24). With three lower energy $t_{2 g}$ orbitals available, the $d^{1}, d^{2}$, and $d^{3}$ ions always form high-spin complexes because there is no need to pair up. Similarly, $d^{8}$ and $d^{9}$ ions always form high-spin complexes: because the $t_{2 g}$ set is filled with six electrons, the two $e_{g}$ orbitals must have either two $\left(d^{8}\right)$ or one $\left(d^{9}\right)$ unpaired electron.

## SAMPLE PROBLEM 23.6 Identifying Complex Ions as High Spin or Low Spin

PROBLEM Iron(II) forms an essential complex in hemoglobin. For each of the two octahedral complex ions $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ and $\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{4-}$, draw an orbital splitting diagram, predict the number of unpaired electrons, and identify the ion as low spin or high spin.
PLAN The $\mathrm{Fe}^{2+}$ electron configuration gives us the number of $d$ electrons, and the spectrochemical series in Figure 23.22 shows the relative strengths of the two ligands. We draw the diagrams, separating the $t_{2 g}$ and $e_{g}$ sets by a greater distance for the strong-field ligand. Then we add electrons, noting that a weak-field ligand gives the maximum number of unpaired electrons and a high-spin complex, whereas a strong-field ligand leads to electron pairing and a low-spin complex.
SOLUTION $\mathrm{Fe}^{2+}$ has the [ Ar$] 3 d^{6}$ configuration. According to Figure $23.22, \mathrm{H}_{2} \mathrm{O}$ produces smaller splitting than $\mathrm{CN}^{-}$. The diagrams are shown in the margin. $\mathrm{The}\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ ion has four unpaired electrons (high spin), and the $\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{4-}$ ion has no unpaired electrons (low spin).
COMMENT 1. $\mathrm{H}_{2} \mathrm{O}$ is a weak-field ligand, so it almost always forms high-spin complexes. 2. These results are correct, but we cannot confidently predict the spin of a complex without having actual values for $\Delta$ and $E_{\text {pairing. }}$ 3. Cyanide ions and carbon monoxide are highly toxic because they interact with the iron cations in proteins.
FOLLOW-UP PROBLEM 23.6 How many unpaired electrons do you expect for $\left[\mathrm{Mn}(\mathrm{CN})_{6}\right]^{3-}$ ? Is this a high-spin or low-spin complex ion?

Crystal Field Splitting in Tetrahedral and Square Planar Complexes Four ligands around a metal ion also cause $d$-orbital splitting, but the magnitude and pattern of the splitting depend on whether the ligands are in a tetrahedral or a square planar arrangement.

- Tetrahedral complexes. With thentonds apprombing fremitheamereofa tetrahedron, none of the five $d$ orbitals is directly in their paths (Figure 23.25). Thus, splitting of $d$-orbital energies is less in a tetrahedral complex than in an octahedral complex having the same ligands:

$$
\Delta_{\text {tetrahedral }}<\Delta_{\text {octahedral }}
$$

Minimal repulsions arise if the ligands approach the $d_{x y}, d_{x z}$, and $d_{y z}$ orbitals closer than they approach the $d_{x^{2}-y^{2}}$ and $d_{z^{2}}$ orbitals. This situation is the opposite of the octahedral case, and the relative $d$-orbital energies are reversed: the $d_{x y}, d_{x z}$, and $d_{y z}$ orbitals become higher in energy than the $d_{x^{2}-y^{2}}$ and $d_{z^{2}}$ orbitals. Only high-spin tetrahedral complexes are known because the magnitude of $\Delta$ is so small.

Figure 23.25 Splitting of $d$-orbital energies by a tetrahedral field of ligands. Electrons in $d_{x y}, d_{x z}$, and $d_{y z}$ orbitals experience greater repulsions than those in $d_{x^{2}-y^{2}}$ and $d_{z^{2}}$ so the tetrahedral splitting pattern is the opposite of the octahedral pattern.

- Square planar complexes. The effects of the ligand field in the square planar case are easier to picture if we imagine starting with an octahedral geometry and then remove the two ligands along the $z$-axis, as depicted in Figure 23.26. With no $z$-axis interactions present, the $d z^{2}$ orbital energy decreases greatly, and the energies of the other orbitals with a $z$-axis component, the $d_{x z}$ and $d_{y z}$, also decrease. As a result, the two $d$ orbitals in the $x y$ plane interact most strongly with the ligands, and because the $d_{x^{2}-y^{2}}$ orbital has its lobes on the axes, its energy is highest. As a consequence of this splitting pattern, square planar complexes with $d^{8}$ metal ions, such as $\left[\mathrm{PdCl}_{4}\right]^{2-}$, are diamagnetic, with four pairs of $d$ electrons filling the four lowest energy orbitals. Thus, as a general rule, square planar complexes are low spin.

Figure 23.26 Splitting of $d$-orbital energies by a square planar field of ligands. In a square planar field, the energies of $d_{x z}, d_{y z}$, and especially $d_{z^{2}}$ orbitals decrease relative to the octahedral pattern.

At this point, a final word about bonding theories may be helpful. As you have seen in our discussions of several other topics, no one model is satisfactory in every respect. The VB approach offers a simple picture of bond formation but does not even attempt to explain color. The crystal field model predicts color and magnetic behavior beautifully but treats the metal ion and ligands as points of opposite charge and thus offers no insight about the covalent nature of metalligand bonding.

Despite its complexity, chemists now rely on a more refined model, called ligand field-molecular orbital theory. This theory combines aspects of the previous two models with MO theory (Section 11.3). We won't explore this model here, but it is a powerful predictive tool, yielding information on bond properties that result from the overlap of metal ion and ligand orbitals as well as information on the spectral and magnetic properties that result from the splitting of a metal ion's $d$ orbitals.
Anaddition to ther importaht chencatapplications, complexes of the transition elements play vital roles in living systems, as the following Chemical Connections essay describes.

## Section Summary

Valence bond theory pictures bonding in complex ions as arising from coordinate covalent bonding between Lewis bases (ligands) and Lewis acids (metal ions). • Ligand lone pairs occupy hybridized metal-ion orbitals to form complex ions with characteristic shapes. - Crystal field theory explains the color and magnetism of complexes. - As the result of a surrounding field of ligands, the $d$-orbital energies of the metal ion split. The magnitude of this crystal field splitting energy ( $\Delta$ ) depends on the charge of the metal ion and the crystal field strength of the ligand. - In turn, $\Delta$ influences the energy of the photon absorbed (color) and the number of unpaired $d$ electrons (paramagnetism). Strong-field ligands create a large $\Delta$ and produce low-spin complexes that absorb light of higher energy (shorter $\lambda$ ); the reverse is true of weakfield ligands. - Several transition metals, such as iron and zinc, are essential dietary trace elements that function in complexes within proteins.

## Chapter Perspective

Our study of the transition elements, a large group of metals with many essential industrial and biological roles, points out once again that macroscopic properties, such as color and magnetism, have their roots at the atomic and molecular levels, which in turn have such a crucial influence on structure. In the next, and final, chapter we explore the core of the atom and learn how we can apply its enormous power.

# Chemical Connections to Nutritional Science Transition Metals as Essential Dietary Trace Elements 

Living things consist primarily of water and complex organic compounds of four building-block elements: carbon, oxygen, hydrogen, and nitrogen (see Figure 2.17, p. 63). All organisms also contain seven other elements, known as macronutrients because they occur in fairly high concentrations. In order of increasing atomic number, they are sodium, magnesium, phosphorus, sulfur, chlorine, potassium, and calcium. In addition, organisms contain a surprisingly large number of other elements in much lower concentrations, and most of these micronutrients, or trace elements, are transition metals.

With the exception of scandium and titanium, all Period 4 transition elements are essential for organisms, and plants require molybdenum (from Period 5) as well. The transition metal ion usually occurs at a bend of a protein chain covalently bonded to surrounding amino acid groups whose N and O atoms act as ligands. Despite the structural complexity of biomolecules, the principles of bonding and $d$-orbital splitting are the same as in simple inorganic systems. Table B23.1 (on page 1056) is a list of the Period 4 transition metals known, or thought, to be essential in human nutrition. In this discussion we focus on iron and zinc.

Iron plays a crucial role in oxygen transport in all vertebrates. The oxygen-transporting protein hemoglobin (Figure B23.1A) consists of four folded protein chains called globins, each cradling the iron-containing complex heme. Heme is a porphyrin, a complex derived from a metal ion and the tetradentate ring ligand known as porphin. Iron(II) is centered in the plane of the porphin ring, forming coordinate covalent bonds with four N lone pairs, resulting in a square planar complex. Aheeneme is boundin
hemoglobin (Figure B23.1B), the complex is octahedral, with the fifth ligand of iron(II) being an N atom from a nearby amino acid (histidine), and the sixth an O atom from either an $\mathrm{O}_{2}$ (shown) or an $\mathrm{H}_{2} \mathrm{O}$ molecule.

Hemoglobin exists in two forms, depending on the nature of the sixth ligand. In the blood vessels of the lungs, where $\mathrm{O}_{2}$ concentration is high, heme binds $\mathrm{O}_{2}$ to form oxyhemoglobin, which is transported in the arteries to $\mathrm{O}_{2}$-depleted tissues. At these tissues, the $\mathrm{O}_{2}$ is released and replaced by an $\mathrm{H}_{2} \mathrm{O}$ molecule to form deoxyhemoglobin, which is transported in the veins back to the lungs. The $\mathrm{H}_{2} \mathrm{O}$ is a weak-field ligand, so the $d^{6}$ ion $\mathrm{Fe}^{2+}$ in deoxyhemoglobin is part of a high-spin complex. Because of the relatively small $d$-orbital splitting, deoxyhemoglobin absorbs light at the red (low-energy) end of the spectrum and looks purplish blue, which accounts for the dark color of venous blood. On the other hand, $\mathrm{O}_{2}$ is a strong-field ligand, so it increases the splitting energy, which gives rise to a low-spin complex. For this reason, oxyhemoglobin absorbs at the blue (high-energy) end of the spectrum, which accounts for the bright red color of arterial blood.

The position of the $\mathrm{Fe}^{2+}$ ion relative to the plane of the porphin ring also depends on this sixth ligand. Bound to $\mathrm{O}_{2}, \mathrm{Fe}^{2+}$ is in the porphin plane; bound to $\mathrm{H}_{2} \mathrm{O}$, it moves out of the plane slightly. This tiny $\left(\sim 60 \mathrm{pm}=6 \times 10^{-11} \mathrm{~m}\right)$ change in the position of $\mathrm{Fe}^{2+}$ on release or attachment of $\mathrm{O}_{2}$ influences the shape of its globin chain, which in turn alters the shape of a neighboring globin chain, triggering the release or attachment of its $\mathrm{O}_{2}$, and so on to the other two globin chains. The very survival of vertebrate life Finthe fesalcelis cooperative "teamwork" by the four globin (continued)

Figure B23.1 Hemoglobin and the octahedral complex in heme. A, Hemoglobin consists of four protein chains, each with a bound heme. (Illustration by Irving Geis. Rights owned by Howard Hughes Medical Institute. Not to be used without permission.) B, In
oxyhemoglobin, the octahedral complex in heme has iron(II) at the center surrounded by the four N atoms of the porphin ring, a fifth N from histidine (below), and an $\mathrm{O}_{2}$ molecule (above).

## Table B23.1 Some Transition Metal Trace Elements in Humans

| Element | Biomolecule Containing Element | Function of Biomolecule |
| :--- | :--- | :--- |
| Vanadium | Protein (?) | Redox couple in fat metabolism (?) |
| Chromium | Glucose tolerance factor | Glucose utilization |
| Manganese | Isocitrate dehydrogenase | Cell respiration |
| Iron | Hemoglobin and myoglobin | Oxygen transport |
|  | Cytochrome $c$ | Cell respiration; ATP formation |
| Cobalt | Catalase | Decomposition of $\mathrm{H}_{2} \mathrm{O}_{2}$ |
| Copper | Cobalamin (vitamin $\mathrm{B}_{12}$ ) | Development of red blood cells |
|  | Ceruloplasmin | Hemoglobin synthesis |
| Zinc | Cytochrome oxidase | Cell respiration; ATP formation |
|  | Carbonic anhydrase | Elimination of CO |
| 2 |  |  |

chains because it allows hemoglobin to pick up $\mathrm{O}_{2}$ rapidly from the lungs and unload it rapidly in the tissues.

Carbon monoxide is highly toxic because it binds to the $\mathrm{Fe}^{2+}$ ion in heme about 200 times more tightly than $\mathrm{O}_{2}$, thereby eliminating the heme group from functioning in the circulation. Like $\mathrm{O}_{2}, \mathrm{CO}$ is a strong-field ligand and produces a bright red, "healthy" look in the individual. Because hemetbimingis@n eqip-D librium process, CO poisoning can be reversed by breathing extremely high concentrations of $\mathrm{O}_{2}$, which effectively displaces CO from the heme:

$$
\text { heme }-\mathrm{CO}+\mathrm{O}_{2} \rightleftharpoons \text { heme }-\mathrm{O}_{2}+\mathrm{CO}
$$

Porphin rings are among the most common biological ligands. Chlorophyll, the photosynthetic pigment of green plants, is a porphyrin with $\mathrm{Mg}^{2+}$ at the center of the porphin ring, and vita$\min B_{12}$ has $\mathrm{Co}^{3+}$ at the center of a very similar ring system. Heme itself is found not only in hemoglobin, but also in proteins called cytochromes that are involved in energy metabolism (see Chemical Connections, pp. 967-968).

The zinc ion occurs in many enzymes, the protein catalysts of cells (see Chemical Connections, pp. 723-724). With its $d^{10}$ configuration, $\mathrm{Zn}^{2+}$ has a tetrahedral geometry, typically with the N atoms of three amino acid groups at three of the positions, and the fourth position free to interact with the molecule whose reaction is being catalyzed (Figure B23.2). In every case studied, the $\mathrm{Zn}^{2+}$ ion acts as a Lewis acid, accepting a lone pair from the reactant as a key step in the catalytic process. Consider the enzyme carbonic anhydrase, which catalyzes the essential reaction between $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$ during respiration:

$$
\mathrm{CO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}^{+}(a q)+\mathrm{HCO}_{3}^{-}(a q)
$$

The $\mathrm{Zn}^{2+}$ ion at the enzyme's active site binds three histidine N atoms and the $\mathrm{H}_{2} \mathrm{O}$ reactant as the fourth ligand. By withdrawing
$\qquad$
electron density from the $\mathrm{O}-\mathrm{H}$ bonds, the $\mathrm{Zn}^{2+}$ makes the $\mathrm{H}_{2} \mathrm{O}$ acidic enough to lose a proton. In the rate-determining step, the resulting bound $\mathrm{OH}^{-}$ion attacks the partially positive C atom of $\mathrm{CO}_{2}$ much more vigorously than could the lone pair of a free water molecule; thus, the reaction rate is higher. One reason the $\mathrm{Cd}^{2+}$ ion is toxic is that it competes with $\mathrm{Zn}^{2+}$ for fitting into the carion is toxic is that it compet
Dbonicanhydaseacte site.

CHAPTER REVIEW GUIDE The following sections provide many aids to help you study this chapter. (Numbers in parentheses refer to pages, unless noted otherwise.)

## Learning Objectives These are concepts and skills you should know after studying this chapter.

Relevant section and/or sample problem (SP) numbers appear in parentheses.

## Understand These Concepts

1. The positions of the $d$ - and $f$-block elements and the general forms of their atomic and ionic electron configurations (Section 23.1)
2. How atomic size, ionization energy, and electronegativity vary across a period and down a group of transition elements and how these trends differ from those of the main-group elements; why the densities of Period 6 transition elements are so high (Section 23.1)
3. Why the transition elements often have multiple oxidation states and why the +2 state is common (Section 23.1)
4. Why metallic behavior (prevalence of ionic bonding and basic oxides) decreases as oxidation state increases (Section 23.1)
5. Why many transition metal compounds are colored and paramagnetic (Section 23.1)
6 . The common +3 oxidation state of lanthanides and the similarity in their $\mathrm{M}^{3+}$ radii; the radioactivity of actinides (Section 23.2)
6. How valence-state electronegativity explains why oxides become more covalent and acidic as the O.N. of the metal increases (Section 23.3)
7. Why Cr and Mn oxoanions are strenger oxidizing agents in
acidic than in basic solutions (Section 23.3 an
acidic than in basic solutions (Section 23.2 )
8. The role silver halides play in black-and-white photography (Section 23.3)
9. How the high density and low melting point of mercury account for its common uses; the toxicity of organomercury compounds (Section 23.3)
10. The coordination numbers, geometries, and ligand structures of complex ions (Section 23.4)
11. How coordination compounds are named and their formulas written (Section 23.4)
12. How Werner correlated the properties and structures of coordination compounds (Section 23.4)
13. The types of constitutional isomerism (coordination and linkage) and stereoisomerism (geometric and optical) of coordination compounds (Section 23.4)
14. How valence bond theory uses hybridization to account for the shapes of octahedral, square planar, and tetrahedral complexes (Section 23.5)
15. How crystal field theory explains that approaching ligands cause $d$-orbital energies to split (Section 23.5)
16. How the relative crystal-field strength of ligands (spectrochemical series) affects the $d$-orbital splitting energy ( $\Delta$ ) (Section 23.5)
17. How the magnitude of $\Delta$ accounts for the energy of light absorbed and, thus, the color of a complex (Section 23.5)
18. How the relative sizes of pairing energy and $\Delta$ determine the occupancy of $d$ orbitals and, thus, the magnetic properties of complexes (Section 23.5)
19. How $d$-orbital splitting in tetrahedral and square planar complexes differs from that in octahedral complexes (Section 23.5)

## Master These Skills

1. Writing electron configurations of transition metal atoms and ions (SP 23.1)
2. Using a partial orbital diagram to determine the number of unpaired electrons in a transition-metal atom or ion (SP 23.2)
E3? Reeognizing the structural components of complex ions (Section 23.4)
3. Naming and writing formulas of coordination compounds (SP 23.3)
4. Determining the type of stereoisomerism in complexes (SP 23.4)
5. Correlating a complex ion's shape with the number and type of hybrid orbitals of the central metal ion (Section 23.5)
6. Using the spectrochemical series to rank complex ions in terms of $\Delta$ and the energy of light absorbed (SP 23.5)
7. Using the spectrochemical series to determine if a complex ion is high or low spin (SP 23.6)

Brief Solutions to FOLLOW-UP PROBLEMS Compare your solutions to these calculations steps and answers.

23.3 (a) Pentaaquabromochromium(III) chloride;
(b) $\mathrm{Ba}_{3}\left[\mathrm{Co}(\mathrm{CN})_{6}\right]_{2}$
23.4 Two sets of cis-trans isomers, and the two cis isomers are optical isomers.

23.5 Both metal ions are $\mathrm{V}^{3+}$; in terms of ligand field energy, $\mathrm{NH}_{3}>\mathrm{H}_{2} \mathrm{O}$, so $\left[\mathrm{V}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ absorbs light of higher energy. 23.6 The metal ion is $\mathrm{Mn}^{3+}$ : $[\mathrm{Ar}] 3 d^{4}$.

Two unpaired $d$ electrons; low-spin complex

## PROBLEMS

Problems with colored numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and provide the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.
Note: In these problems, the term electron configuration refers to the condensed, ground-state electron configuration.

## Properties of the Transition Elements

(Sample Problem 23.1)

## - Concept Review Questions

23.1 How is the $n$ value of the $d$ sublevel of a transition element related to the period number of the element?
23.2 Write the general electron configuration of a transition element (a) in Period 5; (b) in Period 6.
23.3 What is the general rule concerning the order in which electrons are removed from a transition metal atom to form an ion? Give an example from Group 5B(5). Name two types of measurements used to study electron configurations of ions.
23.4 What is the maximum number of unpaired $d$ electrons that an atom or ion can possess? Give an example of an atom and an ion that have this number.
23.5 How does the variation in atomic size across a transition series contrast with the change across the main-group elements of the same period? Why?
23.6 (a) What is the lanthanide contraction? (b) How does it affect atomic size down a group of transition elements? (c) How does it influence the densities of the Period 6 transition elements?
23.7 (a) What is the range in electronegativity across the first (3d) transition series? (b) What is the range across Period 4 of maingroup elements? (c) Explain the difference.
23.8 (a) Explain the major difference between the number of oxidation states of most transition elements and that of most main-
group elements. (b) Why is the +2 oxidation state so common among transition elements?
23.9 (a) What behavior distinguishes paramagnetic and diamagnetic substances? (b) Why are paramagnetic ions common among transition elements but not main-group elements? (c) Why are colored solutions of metal ions common among transition elements but not main-group elements?

## Skill-Building Exercises (grouped in similar pairs)

23.10 Using the periodic table to locate each element, write the electron configuration of (a) V; (b) Y; (c) Hg.
23.11 Using the periodic table to locate each element, write the electron configuration of (a) Ru ; (b) Cu ; (c) Ni .
23.12 Using the periodic table to locate each element, write the electron configuration of (a) Os; (b) Co; (c) Ag.
23.13 Using the periodic table to locate each element, write the electron configuration of (a) Zn ; (b) Mn ; (c) Re.
23.14 Give the electron configuration and the number of unpaired electrons for (a) $\mathrm{Sc}^{3+}$; (b) $\mathrm{Cu}^{2+}$; (c) $\mathrm{Fe}^{3+}$; (d) $\mathrm{Nb}^{3+}$.
23.15 Give the electron configuration and the number of unpaired electrons for: (a) $\mathrm{Cr}^{3+}$; (b) $\mathrm{Ti}^{4+}$; (c) $\mathrm{Co}^{3+}$; (d) $\mathrm{Ta}^{2+}$.
23.16 What is the highest oxidation state for (a) Ta ; (b) Zr ; (c) Mn ? 23.17 What is the highest oxidation state for (a) Nb ; (b) Y ; (c) Tc ?

### 23.18 Which transition metals have a maximum O.N. of +6 ?

23.19 Which transition metals have a maximum O.N. of +4 ?
23.20 In which compound does Cr exhibit greater metallic behavior, $\mathrm{CrF}_{2}$ or $\mathrm{CrF}_{6}$ ? Explain.
 melts above $800^{\circ} \mathrm{C}$. Explain this difference in properties.

### 23.22 Is it more difficult to oxidize Cr or Mo? Explain.

23.23 Is $\mathrm{MnO}_{4}{ }^{-}$or $\mathrm{ReO}_{4}{ }^{-}$a stronger oxidizing agent? Explain.
23.24 Which oxide, $\mathrm{CrO}_{3}$ or CrO , is more acidic in water? Why?
23.25 Which oxide, $\mathrm{Mn}_{2} \mathrm{O}_{3}$ or $\mathrm{Mn}_{2} \mathrm{O}_{7}$, is more basic in water? Why?

## - Problems in Context

23.26 The green patina of Cu -alloy roofs results from corrosion in the presence of $\mathrm{O}_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{CO}_{2}$, and sulfur compounds. The other members of Group $1 \mathrm{~B}(11), \mathrm{Ag}$ and Au , do not form a patina. Corrosion of Cu and Ag in the presence of sulfur compounds leads to a black tarnish, but Au does not tarnish. This pattern is different from that in Group 1A(1), where ease of oxidation increases down the group. Explain these different group patterns.

## The Inner Transition Elements

(Sample Problem 23.2)

## - Concept Review Questions

23.27 What atomic property of the lanthanides leads to their remarkably similar chemical properties?
23.28 (a) What is the maximum number of unpaired electrons in a lanthanide ion? (b) How does this number relate to occupancy of the $4 f$ subshell?
23.29 Which of the actinides are radioactive?

Skill-Building Exercises (grouped in similar pairs)
23.30 Give the electron configuration of (a) La ; (b) $\mathrm{Ce}^{3+}$; (c) Es; (d) $\mathrm{U}^{4+}$.
23.31 Give the electron configuration of (a) Pm ; (b) $\mathrm{Lu}^{3+}$; (c) Th ; (d) $\mathrm{Fm}^{3+}$.
23.32 Only a few lanthanides show an oxidation state other than +3 . Two of these, europium (Eu) and terbium (Tb), are found near the middle of the series, and their unusual oxidation states can be associated with a half-filled $f$ subshell. (a) Write the electron configurations of $\mathrm{Eu}^{2+}, \mathrm{Eu}^{3+}$, and $\mathrm{Eu}^{4+}$. Why is $\mathrm{Eu}^{2+}$ a common ion, whereas $\mathrm{Eu}^{4+}$ is unknown? (b) Write the electron configurations of $\mathrm{Tb}^{2+}, \mathrm{Tb}^{3+}$, and $\mathrm{Tb}^{4+}$. Would you expect Tb to show $\mathrm{a}+2$ or $\mathrm{a}+4$ oxidation state? Explain.
23.33 Cerium ( Ce ) and ytterbium ( Yb ) exhibit some oxidation states in addition to +3 . (a) Write the electron configurations of $\mathrm{Ce}^{2+}, \mathrm{Ce}^{3+}$, and $\mathrm{Ce}^{4+}$. (b) Write the electron configurations of $\mathrm{Yb}^{2+}, \mathrm{Yb}^{3+}$, and $\mathrm{Yb}^{4+}$. (c) In addition to the $3+$ ions, the ions $\mathrm{Ce}^{4+}$ and $\mathrm{Yb}^{2+}$ are stable. Suggest a reason for this stability.

## - Problems in Context

23.34 Which lanthanide has the maximum number of unpaired electrons in both its atom and $3+$ ion? Give the number of unpaired electrons in the atom and ion.

## Highlights of Selected Transition Metals

## - Concept Review Questions

23.35 Why is chromium so useful for decorative electroplating?
23.36 What is valence-state electronegativity? Explain the change in acidity of the oxides of Mn with changing O.N. of the metal.
23.37 What property does manganese confer to steel?
23.38 Why is silver used in jewelry and other decorative objects?
23.39 How is a photographic latent image different from the image you see on a piece of developed film?
23.40 Why is mercury a liquid? Why does it have a $1+$ ion?

## - Problems in Context

E23.41 \#VEenca basic solution of $\mathrm{Cr}(\mathrm{OH})_{4}{ }^{-}$ion is slowly acidified, solid $\mathrm{Cr}(\mathrm{OH})_{3}$ precipitates and then redissolves in excess acid. If $\mathrm{Cr}(\mathrm{OH})_{4}{ }^{-}$exists as $\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}(\mathrm{OH})_{4}{ }^{-}$, write equations that represent these two reactions.
23.42 Use the following data to determine if $\mathrm{Cr}^{2+}(a q)$ can be prepared by the reaction of $\mathrm{Cr}(s)$ with $\mathrm{Cr}^{3+}(a q)$ :

$$
\begin{array}{ll}
\mathrm{Cr}^{3+}(a q)+\mathrm{e}^{-} \longrightarrow \mathrm{Cr}^{2+}(a q) & E^{\circ}=-0.41 \mathrm{~V} \\
\mathrm{Cr}^{3+}(a q)+3 \mathrm{e}^{-} \longrightarrow \mathrm{Cr}(s) & E^{\circ}=-0.74 \mathrm{~V} \\
\mathrm{Cr}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Cr}(s) & E^{\circ}=-0.91 \mathrm{~V}
\end{array}
$$

23.43 When solid $\mathrm{CrO}_{3}$ is dissolved in water, the solution is orange rather than the yellow of $\mathrm{H}_{2} \mathrm{CrO}_{4}$. How does this observation indicate that $\mathrm{CrO}_{3}$ is an acidic oxide?
23.44 Solutions of $\mathrm{KMnO}_{4}$ are used in redox titrations because dark purple $\mathrm{MnO}_{4}{ }^{-}$oxidizing agent changes to the faint pink $\mathrm{Mn}^{2+}$ as it is reduced. The end point occurs when a slight purple remains as more $\mathrm{KMnO}_{4}$ is added. If a sample that has reached this end point stands for a long time, the purple fades and a suspension of a small amount of brown, muddy $\mathrm{MnO}_{2}$ appears. Use standard electrode potentials to explain this result.

## Coordination Compounds

(Sample Problems 23.3 and 23.4)

## - Concept Review Questions

23.45 Describe the makeup of a complex ion, including the nature of the ligands and their interaction with the central metal ion. Explain how a complex ion can be positive or negative and how it occurs as part of a neutral coordination compound.
23.46 What electronic feature must a donor atom of a ligand have?
23.47 What is the coordination number of a metal ion in a complex ion? How does it differ from oxidation number?
23.48 What structural feature is characteristic of a chelate?
23.49 What geometries are associated with the coordination numbers 2,4 , and 6 ?
23.50 What are the coordination numbers of cobalt(III), platinum(II), and platinum(IV) in complexes?
23.51 How is a complex ion a Lewis adduct?
23.52 What does the ending -ate signify in a complex ion name?
23.53 In what order are the metal ion and ligands given in the name of a complex ion?
23.54 Is a linkage isomer a type of constitutional isomer or stereoisomer? Explain.

## - Skill-Building Exercises (grouped in similar pairs)

23.55 Give systematic names for the following formulas:
(a) $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right] \mathrm{Cl}_{2}$
(b) $\left[\mathrm{Cr}(\mathrm{en})_{3}\right]\left(\mathrm{ClO}_{4}\right)_{3}$
(c) $\mathrm{K}_{4}\left[\mathrm{Mn}(\mathrm{CN})_{6}\right]$
23.56 Give systematic names for the following formulas:
(a) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4}\left(\mathrm{NO}_{2}\right)_{2}\right] \mathrm{Cl}$
(b) $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right]\left[\mathrm{Cr}(\mathrm{CN})_{6}\right]$
(c) $\mathrm{K}_{2}\left[\mathrm{CuCl}_{4}\right]$
23.57 What are the charge and coordination number of the central metal ion(s) in each compound of Problem 23.55?
23.58 What are the charge and coordination number of the central metal ion(s) in each compound of Problem 23.56?
23.59 Give systematic names for the following formulas:
(a) $\mathrm{K}\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]$
(b) $\mathrm{Na}_{2}\left[\mathrm{CdCl}_{4}\right]$
(c) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4}\left(\mathrm{H}_{2} \mathrm{O}\right) \mathrm{Br}\right] \mathrm{Br}_{2}$ 23.60 Give systematic names for the following formulas:
(a) $\mathrm{K}\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right) \mathrm{Cl}_{5}\right]$
(b) $\left[\mathrm{Cu}(\mathrm{en})\left(\mathrm{NH}_{3}\right)_{2}\right]\left[\mathrm{Co}(\mathrm{en}) \mathrm{Cl}_{4}\right]$
(c) $\left[\mathrm{Pt}(\mathrm{en})_{2} \mathrm{Br}_{2}\right]\left(\mathrm{ClO}_{4}\right)_{2}$
23.61 What are the charge and coordination number of the central metal ion(s) in each compound of Problem 23.59?
23.62 What are the charge and coordination numberof the central metal ion(s) in each compound of Problem 23.60?
23.63 Give formulas corresponding to the following names:
(a) Tetraamminezinc sulfate
(b) Pentaamminechlorochromium(III) chloride
(c) Sodium bis(thiosulfato)argentate(I)
23.64 Give formulas corresponding to the following names:
(a) Dibromobis(ethylenediamine)cobalt(III) sulfate
(b) Hexaamminechromium(III) tetrachlorocuprate(II)
(c) Potassium hexacyanoferrate(II)
23.65 What is the coordination number of the metal ion and the number of individual ions per formula unit in each of the compounds in Problem 23.63?
23.66 What is the coordination number of the metal ion and the number of individual ions per formula unit in each of the compounds in Problem 23.64?
23.67 Give formulas corresponding to the following names:
(a) Hexaaquachromium(III) sulfate
(b) Barium tetrabromoferrate(III)
(c) Bis(ethylenediamine)platinum(II) carbonate
23.68 Give formulas corresponding to the following names:
(a) Potassium tris(oxalato)chromate(III)
(b) Tris(ethylenediamine)cobalt(III) pentacyanoiodomanganate(II)
(c) Diamminediaquabromochloroaluminum nitrate
23.69 Give the coordination number of the metal ion and the number of ions per formula unit in each compound in Problem 23.67. 23.70 Give the coordination number of the metal ion and the number of ions per formula unit in each compound in Problem 23.68.
23.71 Which of these ligands can participate in linkage isomerism: (a) $\mathrm{NO}_{2}{ }^{-}$; (b) $\mathrm{SO}_{2}$; (c) $\mathrm{NO}_{3}{ }^{-}$? Explain with Lewis structures.
23.72 Which of these ligands can participate in linkage isomerism: (a) $\mathrm{SCN}^{-}$; (b) $\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}$ (thiosulfate); (c) $\mathrm{HS}^{-}$? Explain with Lewis structures.
23.73 For any of the following that can exist as isomers, state the type of isomerism and draw the structures:
(a) $\left[\mathrm{Pt}\left(\mathrm{CH}_{3} \mathrm{NH}_{2}\right)_{2} \mathrm{Br}_{2}\right]$ (b) $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{FCl}\right]$ (c) $\left[\mathrm{Pt}\left(\mathrm{H}_{2} \mathrm{O}\right)\left(\mathrm{NH}_{3}\right) \mathrm{FCl}\right]$
23.74 For any of the following that can exist as isomers, state the type of isomerism and draw the structures:
(a) $\left[\mathrm{Zn}(\mathrm{en}) \mathrm{F}_{2}\right]$
(b) $\left[\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)\left(\mathrm{NH}_{3}\right) \mathrm{FCl}\right]$
(c) $\left[\mathrm{Pd}(\mathrm{CN})_{2}(\mathrm{OH})_{2}\right]^{2-}$
23.75 For any of the following that can exist as isomers, state the type of isomerism and draw the structures:
(a) $\left[\mathrm{PtCl}_{2} \mathrm{Br}_{2}\right]^{2-}$
(b) $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{5}\left(\mathrm{NO}_{2}\right)\right]^{2+}$
(c) $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{I}_{2}\right]^{2+}$
23.76 For any of the following that can exist as isomers, state the type of isomerism and draw the structures:
(a) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Br}_{2}$
(b) $\left[\mathrm{Pt}\left(\mathrm{CH}_{3} \mathrm{NH}_{2}\right)_{3} \mathrm{Cl}\right] \mathrm{Br}$
(c) $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\left(\mathrm{NH}_{3}\right)_{2}\right]^{2+}$

## Problems in Context

23.77 Chromium(III), like cobalt(III), has a coordination number of 6 in many of its complex ions. Compounds are known that have the traditional formula $\mathrm{CrCl}_{3} \cdot n \mathrm{NH}_{3}$, where $n=3$ to 6 . Which of the compounds has an electrical conductivity in aqueous solution similar to that of an equimolar NaCl solution?
23.78 When $\mathrm{MCl}_{4}\left(\mathrm{NH}_{3}\right)_{2}$ is dissolved in water and treated with $\mathrm{AgNO}_{3}, 2 \mathrm{~mol}$ of AgCl precipitates immediately for each mole of $\mathrm{MCl}_{4}\left(\mathrm{NH}_{3}\right)_{2}$. Give the coordination number of M in the complex. 23.79 Palladium, like its group neighbor platinum, forms fourcoordinate $\Phi d(\mathrm{H})$-and fix-coordinate $\mathrm{Pd}(\mathrm{IV})$ complexes. Write modern formulas for the complexes with these compositions:
(a) $\operatorname{PdK}\left(\mathrm{NH}_{3}\right) \mathrm{Cl}_{3}$
(b) $\mathrm{PdCl}_{2}\left(\mathrm{NH}_{3}\right)_{2}$
(c) $\mathrm{PdK}_{2} \mathrm{Cl}_{6}$
(d) $\mathrm{Pd}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{4}$

## Theoretical Basis for the Bonding and Properties of Complexes

(Sample Problems 23.5 and 23.6)

## - Concept Review Questions

23.80 (a) What is a coordinate covalent bond?
(b) Is it involved when $\mathrm{FeCl}_{3}$ dissolves in water? Explain.
(c) Is it involved when HCl gas dissolves in water? Explain.
23.81 According to valence bond theory, what set of orbitals is used by a Period 4 metal ion in forming (a) a square planar complex; (b) a tetrahedral complex?
23.82 A metal ion uses $d^{2} s p^{3}$ orbitals when forming a complex. What is its coordination number and the shape of the complex?
23.83 A complex in solution absorbs green light. What is the color of the solution?
23.84 In terms of the theory of color absorption, explain two ways that a solution can be blue.
23.85 (a) What is the crystal field splitting energy ( $\Delta$ )?
(b) How does it arise for an octahedral field of ligands?
(c) How is it different for a tetrahedral field of ligands?
23.86 What is the distinction between a weak-field ligand and a strong-field ligand? Give an example of each.
23.87 Is a complex with the same number of unpaired electrons as the free gaseous metal ion termed high spin or low spin?
23.88 How do the relative magnitudes of $E_{\text {pairing }}$ and $\Delta$ affect the paramagnetism of a complex?
23.89 Why are there both high-spin and low-spin octahedral complexes but only high-spin tetrahedral complexes?

## - Skill-Building Exercises (grouped in similar pairs)

23.90 Give the number of $d$ electrons ( $n$ of $d^{n}$ ) for the central metal ion in (a) $\left[\mathrm{TiCl}_{6}\right]^{2-}$; (b) $\mathrm{K}\left[\mathrm{AuCl}_{4}\right]$; (c) $\left[\mathrm{RhCl}_{6}\right]^{3-}$.
23.91 Give the number of $d$ electrons ( $n$ of $d^{n}$ ) for the central metal ion in (a) $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]\left(\mathrm{ClO}_{3}\right)_{2}$; (b) $\left[\mathrm{Mn}(\mathrm{CN})_{6}\right]^{2-}$; (c) $\left[\mathrm{Ru}(\mathrm{NO})(\mathrm{en})_{2} \mathrm{Cl}\right] \mathrm{Br}$.
23.92 How many $d$ electrons ( $n$ of $d^{n}$ ) are in the central metal ion in (a) $\mathrm{Ca}\left[\mathrm{IrF}_{6}\right]$; (b) $\left[\mathrm{HgI}_{4}\right]^{2-}$; (c) $[\mathrm{Co}(\mathrm{EDTA})]^{2-}$ ?
23.93 How many $d$ electrons ( $n$ of $d^{n}$ ) are in the central metal ion in (a) $\left[\mathrm{Ru}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{SO}_{4}$; (b) $\mathrm{Na}_{2}\left[\mathrm{Os}(\mathrm{CN})_{6}\right]$; (c) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{CO}_{3} \mathrm{I}\right]$ ?
23.94 Sketch the orientation of the orbitals relative to the ligands in an octahedral complex to explain the splitting and the relative energies of the $d_{x y}$ and the $d_{x^{2}-y^{2}}$ orbitals.
23.95 The two $e_{g}$ orbitals are identical in energy in an octahedral complex but have different energies in a square planar complex, with the $d_{z^{2}}$ orbital being much lower in energy than the $d_{x^{2}-y^{2}}$. Explain with orbital sketches.
23.96 Which of these ions cannot form both high- and low-spin octahedral complexes: (a) $\mathrm{Ti}^{3+}$; (b) $\mathrm{Co}^{2+}$; (c) $\mathrm{Fe}^{2+}$; (d) $\mathrm{Cu}^{2+}$ ?
23.97 Which of these ions cannot form both high- and low-spin octahedral complexes: (a) $\mathrm{Mn}^{3+}$; (b) $\mathrm{Nb}^{3+}$; (c) $\mathrm{Ru}^{3+}$; (d) $\mathrm{Ni}^{2+}$ ?
23.98 Draw orbital-energy splitting diagrams and use the spectrochemical series to show the orbital occupancy for each of the following (assuming that $\mathrm{H}_{2} \mathrm{O}$ is a weak-field ligand):
(a) $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$
(b) $\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2} \mathrm{O}$ OQ $\left[\mathrm{CFF}_{6}\right]$ PDE
23.99 Draw orbital-energy splitting diagrams and use the spectrochemical series to show the orbital occupancy for each of the following (assuming that $\mathrm{H}_{2} \mathrm{O}$ is a weak-field ligand):
(a) $\left[\mathrm{Cr}(\mathrm{CN})_{6}\right]^{3-}$
(b) $\left[\mathrm{Rh}(\mathrm{CO})_{6}\right]^{3+}$
(c) $\left[\mathrm{Co}(\mathrm{OH})_{6}\right]^{4-}$
23.100 Draw orbital-energy splitting diagrams and use the spectrochemical series to show the orbital occupancy for each of the following (assuming that $\mathrm{H}_{2} \mathrm{O}$ is a weak-field ligand):
(a) $\left[\mathrm{MoCl}_{6}\right]^{3-}$
(b) $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$
(c) $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$
23.101 Draw orbital-energy splitting diagrams and use the spectrochemical series to show the orbital occupancy for each of the following (assuming that $\mathrm{H}_{2} \mathrm{O}$ is a weak-field ligand):
(a) $\left[\mathrm{Fe}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{3}\right]^{3-}\left(\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}\right.$ creates a weaker field than $\mathrm{H}_{2} \mathrm{O}$ does.)
(b) $\left[\mathrm{Co}(\mathrm{CN})_{6}\right]^{4-}$
(c) $\left[\mathrm{MnCl}_{6}\right]^{4-}$
23.102 Rank the following in order of increasing $\Delta$ and energy of light absorbed: $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+},\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+},\left[\mathrm{Cr}\left(\mathrm{NO}_{2}\right)_{6}\right]^{3-}$.
23.103 Rank the following in order of decreasing $\Delta$ and energy of light absorbed: $\left[\mathrm{Cr}(\mathrm{en})_{3}\right]^{3+},\left[\mathrm{Cr}(\mathrm{CN})_{6}\right]^{3-},\left[\mathrm{CrCl}_{6}\right]^{3-}$.
23.104 A complex, $\mathrm{ML}_{6}{ }^{2+}$, is violet. The same metal forms a complex with another ligand, Q , that creates a weaker field. What color might $\mathrm{MQ}_{6}{ }^{2+}$ be expected to show? Explain.
$23.105\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ is violet. Another $\mathrm{CrL}_{6}$ complex is green. Can ligand L be $\mathrm{CN}^{-}$? Can it be $\mathrm{Cl}^{-}$? Explain.

## - Problems in Context

23.106 Octahedral $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$ is paramagnetic, whereas planar $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+}$ is diamagnetic, even though both metal ions are $d^{8}$ species. Explain.
23.107 The hexaaqua complex $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ is green, whereas the hexaammonia complex $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$ is violet. Explain.
23.108 Three of the complex ions that are formed by $\mathrm{Co}^{3+}$ are $\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+},\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$, and $\left[\mathrm{CoF}_{6}\right]^{3-}$. These ions have the observed colors (listed in arbitrary order) yellow-orange, green, and blue. Match each complex with its color. Explain.

## Comprehensive Problems

23.109 When neptunium $(\mathrm{Np})$ and plutonium $(\mathrm{Pu})$ were discovered, the periodic table did not include the actinides, so these elements were placed in Group 7B(7) and 8B(8). When americium $(\mathrm{Am})$ and curium $(\mathrm{Cm})$ were synthesized, they were placed in Group $8 \mathrm{~B}(9)$ and $8 \mathrm{~B}(10)$. However, during chemical isolation procedures, Glenn Seaborg and his group, who had synthesized these elements, could not find their compounds among other compounds of these groups, which led Seaborg to suggest they were part of a new inner transition series. (a) How do the electron configurations of these elements support Seaborg's suggestion? (b) The highest fluorides of Np and Pu are hexafluorides, as is the highest fluoride of uranium. How does this chemical evidence support the placement of Np and Pu as inner transition elements rather than transition elements?
23.110 How many different formulas are there for octahedral complexes with a metal M and four ligands $\mathrm{A}, \mathrm{B}, \mathrm{C}$, and D ? Give the number of isomers for each formula and describe the isomers.
23.111 At one time, it was common to write the formula for cop$\operatorname{per}(\mathrm{I})$ chloride as $\mathrm{Cu}_{2} \mathrm{Cl}_{2}$, instead of CuCl , analogously to $\mathrm{Hg}_{2} \mathrm{Cl}_{2}$ for mercury(I) chloride. Use electron configurations to explain why $\mathrm{Hg}_{2} \mathrm{Cl}_{2}$ and CuCl are both correct.
23.112 Correct each name that has an error:
(a) $\mathrm{Na}\left[\mathrm{FeBr}_{4}\right]$, sodium tetrabromoferrate(II)

Erbl
(c) $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{3} \mathrm{I}_{3}\right]$, triamminetriiodocobalt(III)
(d) $\left[\mathrm{V}(\mathrm{CN})_{6}\right]^{3-}$, hexacyanovanadium(III) ion
(e) $\mathrm{K}\left[\mathrm{FeCl}_{4}\right]$, potassium tetrachloroiron(III)
23.113 For the compound $\left[\mathrm{Co}(\mathrm{en})_{2} \mathrm{Cl}_{2}\right] \mathrm{Cl}$, give:
(a) The coordination number of the metal ion
(b) The oxidation number of the central metal ion
(c) The number of individual ions per formula unit
(d) The moles of AgCl that precipitate immediately when 1 mol of compound is dissolved in water and treated with $\mathrm{AgNO}_{3}$
23.114 Hexafluorocobaltate(III) ion is a high-spin complex. Draw the orbital-energy splitting diagram for its $d$ orbitals.
23.115 A salt of each of the ions in Table 23.3 (p. 1029) is dissolved in water. A Pt electrode is immersed in each solution and connected to a $0.38-\mathrm{V}$ battery. All of the electrolytic cells are run for the same amount of time with the same current.
(a) In which cell(s) will a metal plate out? Explain.
(b) Which cell will plate out the least mass of metal? Explain.
23.116 Criticize and correct the following statement: strong-field ligands always give rise to low-spin complexes.
23.117 Two major bidentate ligands used in analytical chemistry are bipyridyl (bipy) and ortho-phenanthroline (o-phen):

o-phenanthroline

Draw structures and discuss the possibility of isomers for
(a) $\left[\mathrm{Pt}(\right.$ bipy $\left.) \mathrm{Cl}_{2}\right]$
(b) $\left[\mathrm{Fe}(o \text {-phen })_{3}\right]^{3+}$
(c) $\left[\mathrm{Co}(\text { bipy })_{2} \mathrm{~F}_{2}\right]^{+}$
(d) $\left[\mathrm{Co}(o \text {-phen })\left(\mathrm{NH}_{3}\right)_{3} \mathrm{Cl}\right]^{2+}$
23.118 The following reaction is a key step in black-and-white photography (see p. 1035):

$$
\mathrm{AgBr}(s)+2 \mathrm{~S}_{2} \mathrm{O}_{3}{ }^{2-}(a q) \longrightarrow \mathrm{Ag}\left(\mathrm{~S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}(a q)+\mathrm{Br}^{-}(a q)
$$

During fixing, 258 mL of hypo (sodium thiosulfate) was used. The hypo concentration was $0.1052 M$ before the AgBr reacted, and 0.0378 M afterward. How many grams of AgBr reacted?
23.119 The metal ion in platinum(IV) complexes, like that in cobalt(III) complexes, has a coordination number of 6 and often has $\mathrm{Cl}^{-}$ions and $\mathrm{NH}_{3}$ molecules as ligands. For the traditional (before the work of Werner) formulas $\mathrm{PtCl}_{4} \cdot 6 \mathrm{NH}_{3}$ and $\mathrm{PtCl}_{4} \cdot 4 \mathrm{NH}_{3}$, (a) give the modern formula and charge of the complex ion, and (b) predict the moles of ions per mole of compound dissolved and moles of AgCl formed with excess $\mathrm{AgNO}_{3}$.
23.120 In 1940, when the elements Np and Pu were prepared, a controversy arose about whether the elements from Ac on were analogs of the transition elements (and related to Y through Mo ) or analogs of the lanthanides (and related to La through Nd). The arguments hinged primarily on comparing observed oxidation states to those of the earlier elements. (a) If the actinides were analogs of the transition elements, what would you predict about the maximum oxidation state for U ? For Np ? (b) If the actinides were analogs of the lanthanides, what would you predict about the maximum oxidation state for U ? For Pu ?
23.121 In many species, a transition metal has an unusually high or low oxidation state. Write balanced equations for the following and find the oxidation state of the transition metal in the product: (a) Iron(III) ion reacts with hypochlorite ion in basic solution to form ferrate ion $\left(\mathrm{FeO}_{4}{ }^{2-}\right), \mathrm{Cl}^{-}$, and water.
(b) Potassium hexacyanomanganate(II) reacts with K metal to form $\mathrm{K}_{6}\left[\mathrm{Mn}(\mathrm{CN})_{6}\right]$.
(c) Heating sodium superoxide $\left(\mathrm{NaO}_{2}\right)$ with $\mathrm{Co}_{3} \mathrm{O}_{4}$ produces $\mathrm{Na}_{4} \mathrm{CoO}_{4}$ and $\mathrm{O}_{2}$ gas.
(d) Vanadium(III) chloride reacts with Na metal under a CO atmosphere to produce $\mathrm{Na}\left[\mathrm{V}(\mathrm{CO})_{6}\right]$ and NaCl .
(e) Barium peroxide reacts with nickel(II) ions in basic solution to produce $\mathrm{BaNiO}_{3}$.
(f) Bubbling CO through a basic solution of cobalt(II) ion produces $\left[\mathrm{Co}(\mathrm{CO})_{4}\right]^{-}, \mathrm{CO}_{3}{ }^{2-}$, and water.
(g) Heating cesium tetrafluorocuprate(II) with $\mathrm{F}_{2}$ gas under pressure gives $\mathrm{Cs}_{2} \mathrm{CuF}_{6}$.
(h) Heating tantalum(V) chloride with Na metal produces NaCl and $\mathrm{Ta}_{6} \mathrm{Cl}_{15}$, in which half of the Ta is in the +2 state.
(i) Potassium tetracyanonickelate(II) reacts with hydrazine $\left(\mathrm{N}_{2} \mathrm{H}_{4}\right)$ in basic solution to form $\mathrm{K}_{4}\left[\mathrm{Ni}_{2}(\mathrm{CN})_{6}\right]$ and $\mathrm{N}_{2}$ gas.
23.122 Draw a Lewis structure with lowest formal charges for $\mathrm{MnO}_{4}{ }^{-}$.
23.123 The coordination compound $\left[\mathrm{Pt}\left(\mathrm{NH}_{3}\right)_{2}(\mathrm{SCN})_{2}\right]$ displays two types of isomerism. Name the types and give names and structures for the six possible isomers.
23.124 In the sepia "toning" of a black-and-white photograph, the image is converted to a rich brownish violet by placing the finished photograph in a solution of gold(III) ions, in which metallic gold replaces the metallic silver. Use Appendix D to explain the chemistry of this process.
23.125 An octahedral complex with three different ligands (A, B, and C) can have formulas with three different ratios of the ligands: $\left[\mathrm{MA}_{4} \mathrm{BC}\right]^{n+}$, such as $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{4}\left(\mathrm{H}_{2} \mathrm{O}\right) \mathrm{Cl}\right]^{2+}$
$\left[\mathrm{MA}_{3} \mathrm{~B}_{2} \mathrm{C}\right]^{n+}$, such as $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3} \mathrm{Br}_{2} \mathrm{Cl}\right]$
$\left[\mathrm{MA}_{2} \mathrm{~B}_{2} \mathrm{C}_{2}\right]^{n+}$, such as $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Br}_{2}\right]^{+}$

For each example, give the name, state the type(s) of isomerism present, and draw all isomers.
23.126 In black-and-white photography, what are the major chemical changes involved in exposing, developing, and fixing?
23.127 In $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{3}$, the $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ ion absorbs visible light in the blue-violet range, and the compound is yelloworange. In $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right] \mathrm{Br}_{3}$, the $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ ion absorbs visible light in the red range, and the compound is blue-gray. Explain these differences in light absorbed and color of the compound.
23.128 Dark green manganate salts contain the $\mathrm{MnO}_{4}{ }^{2-}$ ion. The ion is stable in basic solution but disproportionates in acid to $\mathrm{MnO}_{2}(s)$ and $\mathrm{MnO}_{4}{ }^{-}$. (a) What is the oxidation state of Mn in $\mathrm{MnO}_{4}{ }^{2-}, \mathrm{MnO}_{4}{ }^{-}$, and $\mathrm{MnO}_{2}$ ? (b) Write a balanced equation for the reaction of $\mathrm{MnO}_{4}{ }^{2-}$ in acidic solution.
23.129 Aqueous electrolysis of potassium manganate $\left(\mathrm{K}_{2} \mathrm{MnO}_{4}\right)$ in basic solution is used for the production of tens of thousands of tons of potassium permanganate $\left(\mathrm{KMnO}_{4}\right)$ annually. (a) Write a balanced equation for the electrolysis reaction. (Water is reduced also.) (b) How many moles of $\mathrm{MnO}_{4}^{-}$can be formed if 12 A flows through a tank of aqueous $\mathrm{MnO}_{4}{ }^{2-}$ for 96 h ?
23.130 The actinides $\mathrm{Pa}, \mathrm{U}$, and Np form a series of complex ions, such as the anion in the compound $\mathrm{Na}_{3}\left[\mathrm{UF}_{8}\right]$, in which the central metal ion has an unusual geometry and oxidation state. In the crystal structure, the complex ion can be pictured as resulting from interpenetration of simple cubic arrays of uranium and fluoride ions. (a) What is the coordination number of the metal ion in the complex ion? (b) What is the oxidation state of uranium in the compound? (c) Sketch the complex ion.
23.131 Consider the square planar complextshown atright Which of the structures below are geometric isomers of it?

23.132 (a) What are the central metal ions in chlorophyll, heme, and vitamin $\mathrm{B}_{12}$ ? (b) What similarity in structure do these compounds have?
23.133 Several coordination isomers, with both Co and Cr as $3+$ ions, have the molecular formula $\mathrm{CoCrC}_{6} \mathrm{H}_{18} \mathrm{~N}_{12}$. (a) Give the name and formula of the isomer in which the Co complex ion has six $\mathrm{NH}_{3}$ groups. (b) Give the name and formula of the isomer in which the Co complex ion has one CN and five $\mathrm{NH}_{3}$ groups.
23.134 Several coordination isomers have the molecular formula $\mathrm{Pt}_{2} \mathrm{H}_{12} \mathrm{Cl}_{6} \mathrm{~N}_{4}$. (a) Give the name and standard formula of the isomer in which the Pt complex ion has six Cl groups and a charge of $2-$. (b) Give the name and standard formula of the isomer in which the Pt complex ion has four Cl groups and a charge of $2-$. 23.135 A shortcut to finding optical isomers is to see if the complex has a plane of symmetry-a plane passing through the metal
atom such that every atom on one side of the plane is matched by an identical one at the same distance from the plane on the other side. Any planar complex has a plane of symmetry, since all atoms lie in one plane. Use this approach to determine whether these exist as optical isomers: (a) $\left[\mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{2} \mathrm{Cl}_{2}\right]$ (tetrahedral); (b) $\left[\mathrm{Pt}(\mathrm{en})_{2}\right]^{2+}$; (c) trans- $\left[\mathrm{PtBr}_{4} \mathrm{Cl}_{2}\right]^{2-}$; (d) trans- $\left[\mathrm{Co}(\mathrm{en})_{2} \mathrm{~F}_{2}\right]^{+}$; (e) $c i s-\left[\mathrm{Co}(\mathrm{en})_{2} \mathrm{~F}_{2}\right]^{+}$.
23.136 Werner prepared two compounds by heating a solution of $\mathrm{PtCl}_{2}$ with triethyl phosphine, $\mathrm{P}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{3}$, which is an excellent ligand for Pt . The two compounds gave the same analysis: Pt , $38.8 \%$; $\mathrm{Cl}, 14.1 \%$; C, $28.7 \%$; P, $12.4 \%$; and $\mathrm{H}, 6.02 \%$. Write formulas, structures, and systematic names for the two isomers.
23.137 Some octahedral complexes have distorted shapes. In some, two metal-ligand bonds that are $180^{\circ}$ apart are shorter than the other four. In $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$, for example, two $\mathrm{Cu}-\mathrm{N}$ bonds are 207 pm long, and the other four are 262 pm long. (a) Calculate the longest distance between two N atoms in this complex. (b) Calculate the shortest distance between two N atoms.
23.138 Mercury has a small but significant vapor pressure, and Hg poisoning can occur in poorly ventilated rooms where Hg has been spilled. What is the partial pressure (in torr) of Hg if the maximum concentration at $25^{\circ} \mathrm{C}$ is $20.0 \mathrm{mg} / \mathrm{m}^{3}$ ?
23.139 Normal carbonic anhydrase has zinc at its active site (see Figure B23.2, p. 1056). Suggest a structural reason why carbonic anhydrase synthesized with $\mathrm{Ni}^{2+}, \mathrm{Fe}^{2+}$, or $\mathrm{Mn}^{2+}$ in place of $\mathrm{Zn}^{2+}$ gives an enzyme with less catalytic efficiency.
23.140 The effect of entropy on reactions is evident in the stabilities of certain complexes. (a) Using the criterion of number of product particles, predict which of the foltowing will bexpo Fd in terms of $\Delta S_{\mathrm{rxn}}^{\circ}$ :

$$
\begin{aligned}
& {\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow } \\
& {\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}(a q)+4 \mathrm{NH}_{3}(a q) } \\
& {\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\right)_{2}\right]^{2+}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow } \\
& {\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}(a q)+2 \mathrm{en}(a q) }
\end{aligned}
$$

(b) Given that the $\mathrm{Cu}-\mathrm{N}$ bond strength is approximately the same in both complexes, which complex will be more stable with respect to ligand exchange in water? Explain.
23.141 The extent of crystal field splitting is often determined from spectra. (a) Given the wavelength ( $\lambda$ ) of maximum absorption, find the crystal field splitting energy $(\Delta)$, in $\mathrm{kJ} / \mathrm{mol}$, for each of the following complex ions:

| Ion | $\lambda(n \mathrm{~nm})$ | Ion | $\lambda(\mathrm{nm})$ |
| :--- | :---: | :--- | :---: |
| $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ | 562 | $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ | 966 |
| $\left[\mathrm{Cr}(\mathrm{CN})_{6}\right]^{3-}$ | 381 | $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ | 730 |
| $\left.[\mathrm{CrCl}]_{6}\right]^{3-}$ | 735 | $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ | 405 |
| $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ | 462 | $\left[\mathrm{Rh}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ | 295 |
| $\left[\mathrm{Ir}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ | 244 |  |  |

(b) Construct a spectrochemical series for the ligands in the Cr complexes. (c) Use the Fe data to state how oxidation state affects $\Delta$. (d) Use the Co, Rh, and Ir data to state how period number affects $\Delta$.
23.142 You know the following about a coordination compound:
(1) The partial empirical formula is $\mathrm{KM}\left(\mathrm{CrO}_{4}\right) \mathrm{Cl}_{2}\left(\mathrm{NH}_{3}\right)_{4}$.
(2) It has A (red) and B (blue) crystal forms.
(3) When 1.0 mol of A or B reacts with 1.0 mol of $\mathrm{AgNO}_{3}$, 0.50 mol of a red precipitate forms immediately.
(4) After the reaction in (3), 1.0 mol of A reacts very slowly with 1.0 mol of silver oxalate $\left(\mathrm{Ag}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right)$ to form 2.0 mol of a white precipitate. (Oxalate can displace other ligands.)
(5) After the reaction in (3), 1.0 mol of B does not react further with 1.0 mol of $\mathrm{AgNO}_{3}$.
From this information, determine the following:
(a) The coordination number of M
(b) The group(s) bonded to M ionically and covalently
(c) The stereochemistry of the red and blue forms
23.143 Ionic liquids have many new applications in engineering and materials science. The dissolution of the metavanadate ion in chloroaluminate ionic liquids has been studied:

$$
\mathrm{VO}_{3}^{-}+\mathrm{AlCl}_{4}^{-} \longrightarrow \mathrm{VO}_{2} \mathrm{Cl}_{2}^{-}+\mathrm{AlOCl}_{2}^{-}
$$

(a) What is the oxidation number of V and Al in each ion?
(b) In reactions of $\mathrm{V}_{2} \mathrm{O}_{5}$ with HCl , acid concentration affects the product. At low acid concentration, $\mathrm{VO}_{2} \mathrm{Cl}_{2}{ }^{-}$and $\mathrm{VO}_{3}{ }^{-}$form:

$$
\mathrm{V}_{2} \mathrm{O}_{5}+\mathrm{HCl} \longrightarrow \mathrm{VO}_{2} \mathrm{Cl}_{2}^{-}+\mathrm{VO}_{3}^{-}+\mathrm{H}^{+}
$$

At high acid concentration, $\mathrm{VOCl}_{3}$ forms:

$$
\mathrm{V}_{2} \mathrm{O}_{5}+\mathrm{HCl} \longrightarrow \mathrm{VOCl}_{3}+\mathrm{H}_{2} \mathrm{O}
$$

Balance each equation, and state which, if either, involves a redox process.
(c) What mass of $\mathrm{VO}_{2} \mathrm{Cl}_{2}{ }^{-}$or $\mathrm{VOCl}_{3}$ can form from 12.5 g of $\mathrm{V}_{2} \mathrm{O}_{5}$ and the appropriate concentration of acid?
E23.144Thre erbitafoccupancies for the $d$ orbitals of several complex ions are diagrammed below.

(a) Which diagram corresponds to the orbital occupancy of the cobalt ion in $\left[\mathrm{Co}(\mathrm{CN})_{6}\right]^{3-}$ ?
(b) If diagram D depicts the orbital occupancy of the cobalt ion in $\left[\mathrm{CoF}_{6}\right]^{n}$, what is the value of $n$ ?
(c) $\left[\mathrm{NiCl}_{4}\right]^{2-}$ is paramagnetic and $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ is diamagnetic. Which diagrams correspond to the orbital occupancies of the nickel ions in these species?
(d) Diagram C shows the orbital occupancy of $\mathrm{V}^{2+}$ in the octahedral complex $\mathrm{VL}_{6}$. Can you determine whether L is a strongor weak-field ligand? Explain.

You Are Made of Stars In this false-color composite, the halo of gas known as Cassiopeia A and the tiny neutron star (blue dot at center, white arrow) are all that remain of a massive star that exploded 325 years ago. Its freshly made atomic nuclei were expelled throughout interstellar space, only to be incorporated into new stars, their planets, and the elements and compounds (and creatures) they consist of. In this chapter, we examine atomic nuclei to understand their composition and how we make use of their breakdown and the enormous quantities of energy released when they undergo change.

Nuclear Fusion

Far below the outer fringes of its cloud of electrons lies the atom's tiny, dense core, held together by the strongest force in the universe. For nearly the entire text, we have focused on an atom's electrons, treating the nucleus as their electrostatic anchor, examining the effect of its positive charge on atomic properties and, ultimately, chemical behavior. But, for the scientists probing the structure and behavior of the nucleus itself, there is the scene of real action, one that holds enormous potential benefit and great mystery and wonder.

Society is ambivalent about the applications of nuclear research, however. The promise of abundant energy and treatments for disease comes hand-in-hand with the threat of nuclear waste contamination, reactor accidents, and unimaginable destruction from nuclear war or terrorism. Can the power of the nucleus be harnessed for our benefit, or are the risks too great? In this chapter, we discuss the principles that can help you consider this vital question knowledgably.

The changes that occur in atomic nuclei are strikingly different from chemical changes. In chemical reactions, electrons are shared or transferred to form compounds, while nuclei sit by passively, never changing their identities. In nuclear reactions, the roles are reversed, as electrons in their orbitals take part much less often, while the nuclei undergo changes that, in nearly every case, form different elements. Nuclear reactions are often accompanied by energy changes a million times greater than those in chemical reactions, energy changes so great that changes in mass are detectable. Moreover, nuclear reaction yields and rates are not subject to the effects of pressure, temperature, and catalysis. Table 24.1 summarizes these general differences.

## Concepts \& Skills to Review before you study this chapter

- discovery of the atomic nucleus (Section 2.4)
- protons, neutrons, mass number, and the ${ }_{Z}^{A} \mathrm{X}$ notation (Section 2.5)
- half-life and first-order reaction rate (Section 16.4)

## Table 24.1 Comparison of Chemical and Nuclear Reactions

## Chemical Reactions

1. One substance is converted into another, but atoms never change identity.
2. Orbital electrons are involved as bonds break and form; nuclear particles do not take part.
3. Reactions are accompanied by relatively small changes in energy and no measurable changes in mass.
4. Reaction rates are influenced by temperature, concentration, catalysts, and the compound in which an element occurs.

## Nuclear Reactions

1. Atoms of one element typically are converted into atoms of another element.
2. Protons, neutrons, and other particles are involved; orbital electrons take part much less often.
3. Reactions are accompanied by relatively large changes in energy and measurable changes in mass.
4. Reaction rates depend on number of nuclei, but are not affected by temperature, catalysts, or, except on rare occasions, the compound in which an element occurs.

IN THIS CHAPTER . . . We survey the field of nuclear chemistry, beginning with an investigation of nuclear stability-why some nuclei are stable, whereas others are unstable and undergo radioactive decay. You'll see how radioactivity is detected and how the kinetics of decay is applied. We explore how nuclei synthesized in particle accelerators have extended the periodic table. Then, we consider the effects of radioactive emissions on matter, especially living matter, and focus on some major applications of radioisotopes in science, technology, and medicine. Next, we discuss the central idea of the mass difference that arises when a nucleus forms from its subatomic particles and the energy equivalent to this difference. We then discuss current and future attempts to harness the energy released when heavy nuclei split and lighter ones fuse. Finally, we look at the nuclear processes that create the chemical elements in the stars.

The Tiny, Massive Nucleus If you could strip the electrons from the atoms in an object and compress the nuclei together, the object would lose only a fraction of a percent of its mass, but it would shrink to $0.0000000000001 \%\left(10^{-13} \%\right)$ of its volume. An atom the size of the Houston Astrodome would have a nucleus the size of a marble, which would contain virtually all the atom's mass.

### 24.1 RADIOACTIVE DECAY AND NUCLEAR STABILITY

A stable nucleus remains intact indefinitely, but the great majority of nuclei are unstable. An unstable nucleus exhibits radioactivity: it spontaneously disintegrates, or decays, by emitting radiation. In Section 24.2, you'll see that each type of unstable nucleus has its own characteristic rate of radioactive decay, which can range from less than a billionth of a second to billions of years. In this section, we consider important terms and notation for nuclei, discuss some of the key events in the discovery of radioactivity, and describe the various types of radioactive decay and how to predict which type occurs for a given nucleus.

## The Components of the Nucleus: Terms and Notation

Recall from Chapter 2 that the nucleus contains essentially all the atom's mass but is only about $10^{-5}$ times its radius (or $10^{-15}$ times its volume). Obviously, the nucleus is incredibly dense: about $10^{14} \mathrm{~g} / \mathrm{mL}$. Protons and neutrons, the elementary particles that make up the nucleus, are called nucleons. The term nuclide refers to a nucleus with a particular composition, that is, with specific numbers of the two types of nucleons. Most elements occur in nature as a mixture of isotopes, atoms with the characteristic number of protons of the element but different numbers of neutrons. Therefore, each isotope of an element is a particular nuclide that we identify by its numbers of protons and neutrons. For example, oxygen has three naturally occurring isotopes-the most abundant contains eight protons and eight neutrons, whereas the least abundant contains eight protons and nine neutrons.

The relative mass and charge of a particle-a nucleon, another elementary particle, or a nucleus-is described by the notation ${ }_{Z}^{A} X$, where X is the symbol for the particle. $A$ is the mass mumber or the total number of nucleons, and $Z$ is the charge of the particle; for nucter, A is the sum of protons and neutrons and $Z$ is the number of protons (atomic number). In this notation, the three subatomic elementary particles are

$$
{ }_{-1}^{0} \mathrm{e} \text { (electron), }{ }_{1}^{1} \mathrm{p} \text { (proton), and }{ }_{0}^{1} \mathrm{n} \text { (neutron) }
$$

(A proton is also sometimes represented as ${ }_{1}^{1} \mathrm{H}^{+}$.) The number of neutrons $(N)$ in a nucleus is the mass number $(A)$ minus the atomic number $(Z)$ : $N=A-Z$. The two naturally occurring stable isotopes of chlorine, for example, have 17 protons ( $Z=17$ ), but one has 18 neutrons $\left({ }_{17}^{35} \mathrm{Cl}\right.$, also written $\left.{ }^{35} \mathrm{Cl}\right)$ and the other has 20 $\left({ }_{17}^{37} \mathrm{Cl}\right.$, or $\left.{ }^{37} \mathrm{Cl}\right)$. Nuclides can also be designated with the element name followed by the mass number, for example, chlorine- 35 and chlorine-37. In naturally occurring samples of an element or its compounds, the isotopes of the element are present in specific proportions that can vary only very slightly. Thus, in a sample of sodium chloride (or any Cl-containing substance), $75.77 \%$ of the Cl atoms are chlorine- 35 and the remaining $24.23 \%$ are chlorine- 37 .

To understand this chapter, it's very important that you are comfortable with nuclear notations, so please take a moment to review Sample Problem 2.4 (p. 54) and Problems 2.39 to 2.46 (pp. 82-83).

## The Discovery of Radioactivity and the Types of Emissions

In 1896, the French physicist Antoine-Henri Becquerel discovered, quite by accident, that uranium minerals, even when wrapped in paper and stored in the dark, emit a penetrating radiation that can expose a photographic plate. Becquerel also found that the radiation creates an electric discharge in air, thus providing a means for measuring its intensity. Two years later, a young doctoral student named Marie Sklodowska Curie began a search for other minerals that behaved like uranium in this way. She found that thorium minerals also emit radiation and, most importantly, that the intensity of the radiation is directly proportional to the concen-
tration of the element in the mineral, not to the nature of the mineral or compound in which the element occurs. Curie named the emissions radioactivity and showed that they are unaffected by temperature, pressure, or other physical and chemical conditions.

To her surprise, Curie found that certain minerals containing uranium were even more radioactive than pure uranium, which implied that they contained traces of one or more as yet unknown, highly radioactive elements. She and her husband, the physicist Pierre Curie, set out to isolate all the radioactive components in pitchblende, the principal ore of uranium. After months of painstaking chemical work, they isolated two extremely small, highly radioactive fractions, one that precipitated with bismuth compounds and another that precipitated with alkaline earth compounds. Marie Curie was able to show that these fractions contained two new elements, which she named polonium (after her native Poland) and radium. Polonium ( $\mathrm{Po} ; Z=84$ ), the most metallic member of Group $6 \mathrm{~A}(16)$, lies to the right of bismuth in Period 6. Radium (Ra; $Z=88$ ), which is the heaviest alkaline earth metal, lies under barium in Group 2A(2).

Purifying radium proved to be arduous also. Starting with several tons of pitchblende residues from which the uranium had been extracted, Curie prepared compounds of the larger Group 2A(2) elements, continually separating minuscule amounts of radium compounds from enormously larger amounts of chemically similar barium compounds. It took her four years to isolate 0.1 g of radium chloride, which she melted and electrolyzed to obtain pure metallic radium.

During the next few years, Henri Becquerel, the Curies, and P. Villard in France and Ernest Rutherford and his coworkers in England studied the nature of radioactive emissions. A key finding occurred when Rutherford and his colleague Frederick Soddy observed that elements other than radium were formed when radium decayed. In 1902, they proposed that radioactive emission results in the
 of alchemy and was met with disbelief and ridicule. We now know this idea to be true: when a nuclide of one element decays, it emits radiation and, under most circumstances, changes into a nuclide of a different element. The three natural types of radioactive emission are

- Alpha particles (symbolized $\alpha,{ }_{2}^{4} \alpha$, or ${ }_{2}^{4} \mathrm{He}^{2+}$ ) are identical to helium-4 nuclei.
- Beta particles (symbolized $\beta, \beta^{-}$, or sometimes ${ }_{-1}^{0} \beta$ ) are high-speed electrons. (The emission of electrons from the nucleus may seem strange, but as you'll see shortly, they result from a nuclear reaction.)
- Gamma rays (symbolized $\gamma$, or sometimes ${ }_{0}^{0} \gamma$ ) are very high-energy photons.

Figure 24.1 illustrates the behavior of these emissions in an electric field: $\alpha$ particles curve to a small extent toward the negative plate, $\beta$ particles curve to a greater extent toward the positive plate, and $\gamma$ rays are not affected by the electric field.

## Types of Radioactive Decay; Balancing Nuclear Equations

When a nuclide decays, it forms a nuclide of lower energy, and the excess energy is carried off by the emitted radiation and the recoiling nucleus. The decaying, or reactant, nuclide is called the parent; the product nuclide is called the daughter. Nuclides can decay in several ways. As each of the major types of decay is introduced (summarized in Table 24.2 on the next page), we'll show examples of that type and apply the key principle used to balance nuclear reactions: the total $Z$ (charge, number of protons) and the total $A$ (sum of protons and neutrons) of the reactants equal those of the products:

$$
\begin{align*}
& \text { Total } A  \tag{24.1}\\
& \text { Total } Z
\end{align*} \text { Reactants }=\underset{\operatorname{Total} A}{ } A \text { Products }
$$

Her Brilliant Career Marie Curie (1867-1934) is the only person to be awarded Nobel Prizes in two different sciences, one in physics in 1903 for her research into radioactivity and the other in chemistry in 1911 for the discovery of polonium and the discovery, isolation, and study of radium and its compounds.

Figure 24.1 Three types of radioactive emissions in an electric field. Positively charged $\alpha$ particles curve toward the negative plate; negatively charged $\beta$ particles curve toward the positive plate. (Later, we'll give these the symbol $\beta^{-}$.) The curvature is greater for $\beta$ particles because they have much lower mass. The $\gamma$ rays, uncharged high-energy photons, are unaffected by the field.

Table 24.2 Modes of Radioactive Decay*

*Nuclear chemists consider $\beta^{-}$decay, positron emission, and electron capture to be three decay modes of the more general process known as beta decay (see text).
${ }^{\dagger}$ Neutrinos $(\nu)$ or antineutrinos $(\bar{v})$ are also formed during the three types of beta decay (see the margin note on page 1069). Although we will not include them in other equations in the chapter, keep in mind that antineutrinos are always expelled during $\beta^{-}$decay, and neutrinos are expelled during $\beta^{+}$emission and $\mathrm{e}^{-}$capture.

1. Alpha ( $\boldsymbol{\alpha}$ ) decay involves the loss of an $\alpha$ particle from a nucleus. For each $\alpha$ particle emitted by the parent, $A$ decreases by 4 and $Z$ decreases by 2 in the daughter. Every element beyond bismuth ( $\mathrm{Bi} ; Z=83$ ) is radioactive and exhibits $\alpha$ decay. Thus, $\alpha$ decay is the most common means for a heavy, unstable nucleus to become more stable. In Rutherford's experiment that established the existence of the atomic nucleus (Section 2.4, pp. 50-51), radium was the source of the $\alpha$ particles that were used as projectiles. Radium undergoes $\alpha$ decay to yield radon ( $\mathrm{Rn} ; Z=86$ ):

$$
{ }_{88}^{226} \mathrm{Ra} \longrightarrow{ }_{86}^{22} \mathrm{Rn}+{ }_{2}^{4} \alpha
$$

Note that the $A$ value for Ra equals the sum of the $A$ values for Rn and $\alpha$ $(226=222+4)$, and that the $Z$ value for Ra equals the sum of the $Z$ values for Rn and $\alpha(88=86+2)$.
2. Beta ( $\boldsymbol{\beta}$ ) decay is a more general class of radioactive decay that includes three types: $\beta^{-}$decay, $\beta^{+}$emission, and electron capture.

- $\boldsymbol{\beta}^{-}$decay (or negatron emission) involves the ejection of a $\beta^{-}$particle from the nucleus. This change does not involve expulsion of a $\beta^{-}$particle that was in the nucleus; rather, a neutron is converted into a proton, which remains in the nucleus, and a $\beta^{-}$particle, which is expelled immediately:

$$
{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{1}^{1} \mathrm{p}+{ }_{-1}^{0} \beta
$$

As always, the totals of the $A$ and the $Z$ values for reactant and products are equal. Radioactive nickel-63 becomes stable copper-63 through $\beta^{-}$decay:

$$
{ }_{28}^{63} \mathrm{Ni} \longrightarrow{ }_{29}^{63} \mathrm{Cu}+{ }_{-1}^{0} \beta
$$

Another example is the $\beta^{-}$decay of carbon 14 , used in radiocarbon dating:

$$
{ }_{6}^{14} \mathrm{C} \longrightarrow{ }_{7}^{14} \mathrm{~N}+{ }_{-1}^{0} \beta
$$

Note that $\beta^{-}$decay results in $\alpha$ praduct nuclide with the same A butwith $Z$ one higher (one more proton' than in the reactant nuclide. In other words, an atom of the element with the next higher atomic number is formed.

- Positron $\left(\beta^{+}\right)$emission involves the emission of a $\beta^{+}$particle from the nucleus. A key idea of modern physics is that most fundamental particles have corresponding antiparticles with the same mass but opposite charge. (The neutrino and antineutrino are an example.) The positron is the antiparticle of the electron. Positron emission occurs through a process in which $a$ proton in the nucleus is converted into a neutron, and a positron is expelled. In terms of the effect on $A$ and $Z$, positron emission has the opposite effect of $\beta^{-}$decay: the daughter has the same $A$ but $Z$ is one lower (one fewer proton) than the parent. Thus, an atom of the element with the next lower atomic number forms. Carbon-11, a synthetic radioisotope, decays to a stable boron isotope through $\beta^{+}$emission:

$$
{ }_{6}^{11} \mathrm{C} \longrightarrow{ }_{5}^{11} \mathrm{~B}+{ }_{1}^{0} \beta
$$

- Electron ( $\mathbf{e}^{-}$) capture (EC) occurs when the nucleus interacts with an electron in an orbital from a low atomic energy level. The net effect is that $a$ proton is transformed into a neutron:

$$
{ }_{1}^{1} \mathrm{p}+{ }_{-1}^{0} \mathrm{e} \longrightarrow{ }_{0}^{1} \mathrm{n}
$$

(We use the symbol "e" to distinguish an orbital electron from a beta particle, $\beta$.) The orbital vacancy is quickly filled by an electron that moves down from a higher energy level, and that process continues through still higher energy levels, with x-ray photons and neutrinos carrying off the energy difference in each step. Radioactive iron forms stable manganese through electron capture:

$$
{ }_{26}^{55} \mathrm{Fe}+{ }_{-1}^{0} \mathrm{e} \longrightarrow{ }_{25}^{55} \mathrm{Mn}+h v \text { (x-rays and neutrinos) }
$$

Even though the processes are different, electron capture has the same net effect as positron emission: $Z$ lower by 1, $A$ unchanged.

The Little Neutral One A neutral particle called an antineutrino ( $\bar{v}$ ) is also emitted during $\beta^{-}$decay:

$$
{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{1}^{1} \mathrm{p}+{ }_{-1}^{0} \beta+\bar{v}
$$

Its antiparticle, the neutrino $(\nu)$, is emitted during the other two types of beta decay. Theory suggests that these particles have masses much less than $10^{-4}$ times that of an electron, and that at least $10^{9}$ of them exist for every proton. Neutrinos and antineutrinos interact with matter so slightly that it would take a piece of lead 1 lightyear thick to absorb them. We will not discuss them further, except to mention that experiments in Japan in the 1990s detected neutrinos and obtained evidence that they do indeed have mass. Using a cathedral-sized pool containing 50,000 tons of ultra-pure water buried 1 mile underground in a zinc mine, an international team of scientists obtained results suggesting that these particles may account for a portion of the "missing" matter and dark energy in the universe.
3. Gamma $(\gamma)$ emission involves the radiation of high-energy $\gamma$ photons from an excited nucleus. Just as an atom in an excited electronic state reduces its energy by emitting photons, usually in the UV and visible ranges (see Section 7.2), a nucleus in an excited state lowers its energy by emitting $\gamma$ photons, which are of much higher energy (much shorter wavelength) than UV photons. Many nuclear processes leave the nucleus in an excited state, so $\gamma$ emission accompanies many other (but mostly $\beta$ ) types of decay. Several $\gamma$ photons (also called $\gamma$ rays) of different energies can be emitted from an excited nucleus as it returns to the ground state. Some of Marie Curie's experiments involved the release of $\gamma$ rays, such as

$$
{ }_{84}^{215} \mathrm{Po} \longrightarrow{ }_{82}^{211} \mathrm{~Pb}+{ }_{2}^{4} \alpha \text { (several } \gamma \text { emitted) }
$$

Gamma emission is common subsequent to $\beta^{-}$decay, as in the following:

$$
{ }_{43}^{99} \mathrm{Tc} \longrightarrow{ }_{44}^{99} \mathrm{Ru}+{ }_{-1}^{0} \beta \text { (several } \gamma \text { emitted) }
$$

Because $\gamma$ rays have no mass or charge, $\gamma$ emission does not change $A$ or $Z$. Two gamma rays are emitted when a particle and an antiparticle annihilate each other. In the medical technique known as positron-emission tomography (which we discuss in Section 24.5), a positron and an electron annihilate each other (with all $A$ and $Z$ values shown):

$$
{ }_{1}^{0} \beta+{ }_{-1}^{0} \mathrm{e} \longrightarrow 2{ }_{0}^{0} \gamma
$$

SAMPLE PROBLEM 24.1 Writing Equations for Nuclear Reactions
PROBLEM Write balanced equations for the following nuclear reactions:
(a) Naturally occurring thorium-232 undergoes $\alpha$ decay.
(b) Zirconium-86 undergoes electron capture.

PLAN We first write a skeleton equation that includes the mass numbers, atomic numbers, and symbols of all the particles on the correct sides of the equation, showing the unknown product particle as ${ }_{Z}^{A} X$. Then, because the total of mass numbers and the total of charges on the left side and the right side must be equal, we solve for $A$ and $Z$, and use $Z$ to determine X from the periodic table.
SOLUTION (a) Writing the skeleton equation, with the $\alpha$ particle as a product:

$$
{ }_{90}^{232} \mathrm{Th} \longrightarrow{ }_{Z}^{A} \mathrm{X}+{ }_{2}^{4} \alpha
$$

Solving for $A$ and $Z$ and balancing the equation: For $A, 232=A+4$, so $A=228$. For $Z, 90=Z+2$, so $Z=88$. From the periodic table, we see that the element with $Z=88$ is radium ( Ra ). Thus, the balanced equation is

$$
{ }_{90}^{232} \mathrm{Th} \longrightarrow{ }_{88}^{228} \mathrm{Ra}+{ }_{2}^{4} \alpha
$$

(b) Writing the skeleton equation, with the captured electron as a reactant:

$$
{ }_{40}^{86} \mathrm{Zr}+{ }_{-1}^{0} \mathrm{e} \longrightarrow{ }_{Z}^{A} \mathrm{X}
$$

Solving for $A$ and $Z$ and balancing the equation: For $A, 86+0=A$, so $A=86$. For $Z$, $40+(-1)=Z$, so $Z=39$. The element with $Z=39$ is yttrium ( Y ), so we have

$$
{ }_{40}^{86} \mathrm{Zr}+{ }_{-1}^{0} \mathrm{e} \longrightarrow{ }_{39}^{86} \mathrm{Y}
$$

CHECK Always read across superscripts and then across subscripts, with the yield arrow as an equal sign, to check your arithmetic. In part (a), for example, $232=228+4$, and $90=88+2$.
FOLLOW-UP PROBLEM 24.1 Write a balanced equation for the reaction in which a nuclide undergoes $\beta^{-}$decay and produces cesium-133.

## Nuclear Stability and the Mode of Decay

There are several ways that an unstable nuclide might decay, but can we predict how it will decay? Indeed, can we predict whether a given nuclide will decay at all? Our knowledge of the nucleus is much less complete than that of the whole atom, but some patterns emerge by observing the naturally occurring nuclides.

The Band of Stability Two key factors determine the stability of a nuclide. The first is the number of neutrons $(N)$, the number of protons ( $Z$ ), and their ratio $(N / Z)$, which we calculate from $(A-Z) / Z$. This factor relates primarily to nuclides that undergo one of the three modes of $\beta$ decay. The second factor affecting stability is the total mass of the nuclide, which mostly relates to nuclides that undergo $\alpha$ decay.

Figure 24.2 A is a plot of number of neutrons vs. number of protons for all stable nuclides. Note the following:

- The points form a narrow band of stability that gradually curves above the line for $N=Z(N / Z=1)$.
- Very few stable nuclides exist with $N / Z<1$; the only two are ${ }_{1}^{1} \mathrm{H}$ and ${ }_{2}^{3} \mathrm{He}$.
- Many lighter nuclides with $N=Z$ are stable, such as ${ }_{2}^{4} \mathrm{He},{ }_{6}^{12} \mathrm{C},{ }_{8}^{16} \mathrm{O}$, and ${ }_{10}^{20} \mathrm{Ne}$; the heaviest of these is ${ }_{20}^{40} \mathrm{Ca}$. Thus, for lighter nuclides, one neutron for each proton $(N=Z)$ is enough to provide stability.
- The $N / Z$ ratio of stable nuclides gradually increases as $Z$ increases. A few examples appear on the figure: for ${ }_{26}^{56} \mathrm{Fe}, N / Z=1.15$; for ${ }_{47}^{107} \mathrm{Ag}, N / Z=1.28$; for ${ }_{74}^{184} \mathrm{~W}, N / Z=1.49$, and, finally, for ${ }_{83}^{209} \mathrm{Bi}, N / Z=1.52$. Thus, for heavier stable nuclides, $N>Z(N / Z>1)$, and $N$ increases faster than $Z$. As we discuss below, if $N / Z$ of a nuclide is either too high (above the band) or not high enough (below the band), the nuclide is unstable and undergoes one of the three modes of beta decay.

Figure 24.2 A plot of number of neutrons vs. number of protons for the stable nuclides. A, A plot of $N$ vs. $Z$ for all stable nuclides gives rise to a narrow band that veers above $N / Z=1$ shortly beyond $Z=10$. The $N / Z$ values for several stable nuclides are given. The most common modes of decay for unstable nuclides in a particular region are shown: nuclides with a high $N / Z$ ratio often undergo $\beta^{-}$decay; those with a low ratio undergo $e^{-}$capture or $\beta^{+}$emission; heavy nuclei beyond the stable band undergo $\alpha$ decay. $\mathbf{B}$, The blue box in part $A$ is expanded to show the stable and many of the unstable nuclides in that area. Note the modes of decay: $\alpha$ decay decreases both $N$ and $Z$ by $2 ; \beta^{-}$decay decreases $N$ and increases $Z$ by $1 ; \beta^{+}$emission and $\mathrm{e}^{-}$capture increase $N$ and decrease $Z$ by 1 .

| Table 24.3 | Number of Stable |  |

| Table 24.4 | An Even-Odd |
| :--- | :--- | :---: |
| Breakdown of the Stable Nuclides |  |

- All nuclides with $Z>83$ are unstable. This means that all nuclides with a higher $Z$-the largest members of main groups $1 \mathrm{~A}(1)$ through $8 \mathrm{~A}(18)$, actinium and the actinides $(Z=89-103)$, and the other elements of the fourth $(6 d)$ transition series $(Z=104-112)$-are radioactive, and, as we point out below, undergo $\alpha$ decay.

Stability and Nuclear Structure Given that protons are positively charged and neutrons are uncharged, what holds the nucleus together? Nuclear scientists answer this question and explain the importance of $N$ and $Z$ values in terms of two opposing forces. Electrostatic repulsive forces between protons would break the nucleus apart if not for the presence of an attractive force called the strong force, which exists between all nucleons (protons and neutrons). This force is 137 times stronger than the repulsive force but operates only over the short distances within the nucleus. Competition between the attractive strong force and the repulsive electrostatic force determines nuclear stability.

The oddness or evenness of $N$ and $Z$ values is related to some important patterns of nuclear stability. Two interesting points become apparent when we classify the known stable nuclides:

- Elements with an even $Z$ (number of protons) usually have a larger number of stable nuclides than elements with an odd $Z$. Table 24.3 demonstrates this point for cadmium $(Z=48)$ through xenon $(Z=54)$.
- Well over half the stable nuclides have both even $N$ and even $Z$ (Table 24.4). Only four nuclides with odd $N$ and odd $Z$ are stable: ${ }_{1}^{2} \mathrm{H},{ }_{3}^{6} \mathrm{Li},{ }_{5}^{10} \mathrm{~B}$, and ${ }_{7}^{14} \mathrm{~N}$.
One model of nuclear structure that attempts to explain the stability of even values of $N$ and $Z$ postulates that protons and neutrons lie in nucleon energy levels, and that greater stability results from the pairing of spins of like nucleons. (Note the analogy to electron energy levels and the stability from pairing of elec-

Just as noble gases-with 2, 10, 18, 36, 54, and 86 electrons-are exceptionally stable because they have filled electron levels, nuclides with $N$ or $Z$ values of $2,8,20,28,50,82$ (and $N=126$ ) are exceptionally stable. These so-called magic numbers are thought to correspond to the numbers of protons or neutrons in filled nucleon levels. A few examples are ${ }_{22}^{50} \mathrm{Ti}(N=28)$, ${ }_{38}^{88} \mathrm{Sr}(N=50)$, and the ten stable nuclides of tin $(Z=50)$. Some extremely stable nuclides have doubly magic numbers: ${ }_{2}^{4} \mathrm{He},{ }_{8}^{16} \mathrm{O},{ }_{20}^{40} \mathrm{Ca}$, and ${ }_{82}^{208} \mathrm{~Pb}(N=126)$.

## SAMPLE PROBLEM 24.2 Predicting Nuclear Stability

PROBLEM Which of the following nuclides would you predict to be stable and which radioactive: (a) ${ }_{10}^{18} \mathrm{Ne}$; (b) ${ }_{16}^{32} \mathrm{~S}$; (c) ${ }_{90}^{236} \mathrm{Th}$; (d) ${ }_{56}^{123} \mathrm{Ba}$ ? Explain.
PLAN In order to evaluate the stability of each nuclide, we determine the $N$ and $Z$ values, the $N / Z$ ratio from $(A-Z) / Z$, the value of $Z$, stable $N / Z$ ratios (from Figure 24.2), and whether $Z$ and $N$ are even or odd.
SOLUTION (a) Radioactive. This nuclide has $N=8(18-10)$ and $Z=10$, so $N / Z=$ $\frac{18-10}{10}=0.8$. Except for hydrogen-1 and helium-3, no nuclides with $N<Z$ are stable; despite even $N$ and $Z$, this nuclide has too few neutrons to be stable.
(b) Stable. This nuclide has $N=Z=16$, so $N / Z=1.0$. With $Z<20$ and even $N$ and $Z$, this nuclide is most likely stable.
(c) Radioactive. This nuclide has $Z=90$, and every nuclide with $Z>83$ is radioactive.
(d) Radioactive. This nuclide has $N=67$ and $Z=56$, so $N / Z=1.20$. For $Z$ values of 55 to 60 , Figure 24.2 A shows $N / Z \geq 1.3$, so this nuclide has too few neutrons to be stable. CHECK By consulting a table of isotopes, such as the one in the CRC Handbook of Chemistry and Physics, we find that our predictions are correct.
FOLLOW-UP PROBLEM 24.2 Why is ${ }_{15}^{31} \mathrm{P}$ stable but ${ }_{15}^{30} \mathrm{P}$ unstable?

Predicting the Mode of Decay An unstable nuclide generally decays in a mode that shifts its $N / Z$ ratio toward the band of stability. This fact is illustrated in Figure 24.2B, which expands a small region of Figure 24.2A to show the stable and many of the unstable nuclides in that region, as well as their modes of decay. Note the following points:

1. Neutron-rich nuclides. Nuclides with too many neutrons for stability (a high $N / Z$ ) lie above the band of stability. They undergo $\beta^{-}$decay, which converts a neutron into a proton, thus reducing the value of $N / Z$.
2. Proton-rich nuclides. Nuclides with too many protons for stability (a low N/Z) lie below the band. They undergo $\beta^{+}$emission and/or $e^{-}$capture, both of which convert a proton into a neutron, thus increasing the value of $N / Z$. (The rate of $\mathrm{e}^{-}$capture increases with $Z$, so $\beta^{+}$emission is more common among lighter elements and $\mathrm{e}^{-}$capture more common among heavier elements.)
3. Heavy nuclides. Nuclides with $Z>83$ are too heavy to be stable and undergo $\alpha$ decay, which reduces their $Z$ and $N$ values by two units per emission.
If we have the information in Figure 24.2, predicting the mode of decay of an unstable nuclide is just a matter of comparing its $N / Z$ ratio with those in the nearby region of the band of stability. But, even when Figure 24.2 is not available, we can often make an educated guess at the mode of decay. The atomic mass of an element represents the weighted average of its naturally occurring isotopes, so we would expect the mass number $A$ of a stable nuclide to be relatively close to the atomic mass. If an unstable nuclide of the element (given $Z$ ) has an $A$ value higher than the atomic mass, it is neutron rich and will probably decay by $\beta^{-}$emission. If, on the other hand, the unstable nuclide has an $A$ value lower than the atomic mass, it is proton rich and will probably decay by $\beta^{+}$emission and/or $\mathrm{e}^{-}$capture. In the next sample problem, we compare the mass number with
 then check the prediction with the $N / Z$ values in Figure 24.2.

## SAMPLE PROBLEM 24.3 Predicting the Mode of Nuclear Decay

PROBLEM Use the atomic mass of the element to predict the mode(s) of decay of the following radioactive nuclides: (a) ${ }_{5}^{12} \mathrm{~B}$; (b) ${ }_{92}^{234} \mathrm{U}$; (c) ${ }_{33}^{81} \mathrm{As}$; (d) ${ }_{57}^{127} \mathrm{La}$.
PLAN If the nuclide is too heavy to be stable ( $Z>83$ ), it undergoes $\alpha$ decay. For other cases, we use the $Z$ value to locate the element in the periodic table and obtain its atomic mass. If the mass number of the nuclide is higher than the atomic mass, the nuclide has too many neutrons: $N$ too high $\Rightarrow \beta^{-}$decay. If the mass number is lower than the atomic mass, the nuclide has too many protons: $Z$ too high $\Rightarrow \beta^{+}$emission and/or $\mathrm{e}^{-}$capture.
SOLUTION (a) This nuclide has $Z=5$, which is boron (B), and the atomic mass is 10.81 . The nuclide's $A$ value of 12 is higher than its atomic mass, so this nuclide is neutron rich. It will probably undergo $\beta^{-}$decay lowering $N$ to 6 and raising $Z$ to 6 to form the stable ${ }_{6}^{12} \mathrm{C}$.
(b) This nuclide has $Z=92$, so it will undergo $\alpha$ decay and decrease its total mass.
(c) This nuclide has $Z=33$, which is arsenic (As), and the atomic mass is 74.92. The $A$ value of 81 is higher, so this nuclide is neutron rich and will probably undergo $\beta^{-}$decay. (d) This nuclide has $Z=57$, which is lanthanum (La), and the atomic mass is 138.9. The $A$ value of 127 is lower, so this nuclide is proton rich and will probably undergo $\beta^{+}$emission and/or $\mathrm{e}^{-}$capture.
CHECK To confirm our predictions in (a), (c), and (d), let's compare each nuclide's $N / Z$ ratio to those in the band of stability. (a) This nuclide has $N=7$ and $Z=5$, so $N / Z=$ 1.40 , which is too high for this region of the band, so it will undergo $\beta^{-}$decay. (c) This nuclide has $N=48$ and $Z=33$, so $N / Z=1.45$, which is too high for this region of the band, so it undergoes $\beta^{-}$decay. (d) This nuclide has $N=70$ and $Z=57$, so $N / Z=1.23$, which is too low for this region of the band, so it undergoes $\beta^{+}$emission and/or $\mathrm{e}^{-}$capture. Our predictions based on N/Z values were the same as those based on atomic mass. COMMENT Both possible modes of decay are observed for the nuclide in part (d).

Figure 24.3 The ${ }^{238} U$ decay series. Uranium-238 (top right) undergoes a series of 14 steps involving $\alpha$ or $\beta^{-}$decay until lead-206 forms (bottom left).

FOLLOW-UP PROBLEM 24.3 Use the $A$ value for the nuclide and the atomic mass in the periodic table to predict the mode of decay of (a) ${ }_{26}^{61} \mathrm{Fe}$; (b) ${ }_{95}^{241} \mathrm{Am}$.

Decay Series A parent nuclide may undergo a series of decay steps before a stable daughter nuclide forms. The succession of steps is called a decay series, or disintegration series, and is typically depicted on a gridlike display. Figure 24.3 shows the decay series from uranium-238 to lead-206. Numbers of neutrons $(N)$ are plotted against numbers of protons $(Z)$ to form the grid, which displays a series of $\alpha$ and $\beta^{-}$decays. The typical zigzag pattern arises because $N>Z$, which means that $\alpha$ decay, which reduces both $N$ and $Z$ by two units, decreases $Z$ by a slightly greater percentage than it does $N$. Therefore, $\alpha$ decays result in neutron-rich daughters, which undergo $\beta^{-}$decay to gain more stability. Note that a given nuclide can undergo both types of decay. (Gamma emission accompanies many of these steps but does not affect the type of nuclide.) This series is one of three that occur in nature. All end with isotopes of lead whose nuclides all have one $(Z=82)$ or two $(N=126, Z=82)$ magic numbers. A second series begins with uranium-235 and ends with lead-207, and a third begins with thorium-232 and ends with lead-208. (Neptunium-237 began a fourth series, but its half-life is so much less than the age of Earth that only traces of it remain today.)

## Section Summary

Nuclear reactions are normally not affected by reaction conditions or chemical composition and release much more energy than chemical reactions. - To become more stable, a radioactive nuclide may emit $\alpha$ particles ( ${ }_{2}^{4} \mathrm{He}$ nuclei), $\beta$ particles ( $\beta^{-}$or ${ }_{-1}^{0} \beta$; high-speed electrons), positrons ( $\beta^{+}$or ${ }_{1}^{0} \beta$ ), or $\gamma$ rays (high-energy photons) or may capture an orbital electron $\left({ }_{-1}{ }^{0} \mathrm{e}\right)$. - A narrow band of neutron-to-proton ratios (N/Z) inelydesthose of the stable nudides eGerain "magic numbers" of neutrons and protons are associated with very stable nuclides. - By comparing a nuclide's mass number with the atomic mass and its $N / Z$ ratio with those in the band of stability, we can predict that, in general, neutron-rich nuclides undergo $\beta^{-}$decay and proton-rich nuclides undergo $\beta^{+}$emission and/or $\mathrm{e}^{-}$capture. Heavy nuclides $(Z>83)$ undergo $\alpha$ decay. - Three naturally occurring decay series all end in isotopes of lead.

### 24.2 THE KINETICS OF RADIOACTIVE DECAY

Chemical and nuclear systems both tend toward maximum stability. Just as the concentrations in a chemical system change in a predictable direction to give a stable equilibrium ratio, the type and number of nucleons in an unstable nucleus change in a predictable direction to give a stable $N / Z$ ratio. As you know, however, the tendency of a chemical system to become more stable tells nothing about how long that process will take, and the same holds true for nuclear systems. In this section, we examine the kinetics of nuclear change; later, we'll examine the energetics of nuclear change. To begin, a Tools of the Laboratory essay on page 1075 describes how radioactivity is detected and measured.

## The Rate of Radioactive Decay

Radioactive nuclei decay at a characteristic rate, regardless of the chemical substance in which they occur. The decay rate, or activity $(\mathscr{A})$, of a radioactive sample is the change in number of nuclei ( $\mathcal{N}$ ) divided by the change in time $(t)$. As we saw with chemical reaction rates, because the number of nuclei is decreasing, a minus sign precedes the expression for the decay rate:

$$
\text { Decay rate }(\mathscr{A})=-\frac{\Delta \mathcal{N}}{\Delta t}
$$

## Counters for the Detection of Radioactive Emissions

Radioactive emissions interact with atoms in surrounding materials. To determine the rate of nuclear decay, we measure the radioactivity of a sample by observing the effects of these interactions over time. Because these effects can be electrically amplified billions of times, it is even possible to detect the decay of a single nucleus. Ionization counters and scintillation counters are two devices used to measure radioactive emissions.

An ionization counter detects radioactive emissions as they ionize a gas. Ionization produces free electrons and gaseous cations, which are attracted to electrodes that conduct a current to a recording device. The most common type of ionization counter is a Geiger-Müller counter (Figure B24.1). It consists of a tube filled with an argon-methane mixture; the tube housing acts as the cathode, and a thin wire in the center of the tube acts as the anode. Emissions from the sample enter the tube through a thin window and strike argon atoms, producing free electrons that are accelerated toward the anode. These electrons collide with other argon atoms and free more electrons in an avalanche effect. The current created is amplified and appears as a meter reading and/or an audible click. An initial release of 1 electron can release $10^{10}$ electrons in a microsecond, giving the Geiger-Müller counter great sensitivity.

In a scintillation counter, radioactive emissions are detected by their ability to excite atoms and cause them to emit light. The light-emitting substance in the counter, called a phosphor, is coated onto part of a photomultiplier tube, a device that increases the original electrical signal. Incoming radioactive particles strike the phosphor, which emits photons. Eachphoton, in turn, strikesa
cathode, releasing an electron through the photoelectric effect (Section 7.1). This electron hits other portions of the tube that release increasing numbers of electrons, and the resulting current is recorded. Liquid scintillation counters employ an organic mixture that contains a phosphor and a solvent (Figure B24.2). This "cocktail" dissolves the sample and emits light when excited by the emission. These counters are often used to measure $\beta^{-}$emissions from dissolved biological samples, particularly those containing compounds of ${ }^{3} \mathrm{H}$ and ${ }^{14} \mathrm{C}$.

Figure B24.2 Vials of a scintillation "cocktail" emitting light. A radioactive substance dissolved in an organic mixture (cocktail) emits particles that cause excitation of a phosphor, which emits pulses of light. The number of pulses is proportional to the concentration of Fthe radioactive sybstance.

Figure B24.1 Detection of radioactivity by an ionization counter. When an Ar atom absorbs the energy of a radioactive particle (red), it is ionized to an $\mathrm{Ar}^{+}$ion (purple) and an electron (yellow). The free electron collides with and ionizes another Ar atom. As the process continues, the $\mathrm{Ar}^{+}$ions migrate to the negative electrode, and the electrons migrate to the positive electrode, resulting in a current.

Figure 24.4 Decrease in number of ${ }^{14} \mathrm{C}$ nuclei over time. A plot of number of ${ }^{14} \mathrm{C}$ nuclei vs. time gives a decreasing curve. In each half-life ( 5730 years), half the ${ }^{14} \mathrm{C}$ nuclei present undergo decay. A plot of mass of ${ }^{14} \mathrm{C}$ (or any other variable proportional to number of nuclei) vs. time has the same shape. (As you'll see in Figure 24.5, p. 1079, a plot of the natural logarithm of the variable on the $y$-axis vs. time gives a straight line.)

The SI unit of radioactivity is the becquerel (Bq); it is defined as one disintegration per second $(\mathrm{d} / \mathrm{s}): 1 \mathrm{~Bq}=1 \mathrm{~d} / \mathrm{s}$. A much larger and more common unit of radioactivity is the curie ( $\mathbf{C i}$ ). Originally, the curie was defined as the number of disintegrations per second in 1 g of radium- 226 , but it is now a fixed quantity:

$$
\begin{equation*}
1 \mathrm{Ci}=3.70 \times 10^{10} \mathrm{~d} / \mathrm{s} \tag{24.2}
\end{equation*}
$$

Because the curie is so large, the millicurie ( mCi ) and microcurie ( $\mu \mathrm{Ci}$ ) are commonly used. We often express the radioactivity of a sample in terms of specific activity, the decay rate per gram.

An activity is meaningful only when we consider the large number of nuclei in a macroscopic sample. Suppose there are $1 \times 10^{15}$ radioactive nuclei of a particular type in a sample and they decay at a rate of $10 \%$ per hour. Although any particular nucleus in the sample might decay in a microsecond or in a million hours, the average of all decays results in $10 \%$ of the entire collection of nuclei disintegrating each hour. During the first hour, $10 \%$ of the original number, or $1 \times 10^{14}$ nuclei, will decay. During the next hour, $10 \%$ of the remaining $9 \times 10^{14}$ nuclei, or $9 \times 10^{13}$ nuclei, will decay. During the next hour, $10 \%$ of those remaining will decay, and so forth. Thus, for a large collection of radioactive nuclei, the number decaying per unit time is proportional to the number present:

$$
\text { Decay rate }(\mathscr{A}) \propto \mathcal{N} \quad \text { or } \quad \mathscr{A}=k \mathcal{N}
$$

where $k$ is called the decay constant and is characteristic of each type of nuclide. The larger the value of $k$, the higher is the decay rate: larger $k \Rightarrow$ higher $\mathscr{A}$.

Combining the two rate expressions just given, we obtain

$$
\begin{equation*}
\mathscr{A}=-\frac{\Delta \mathcal{N}}{\Delta t}=k \mathcal{N} \tag{24.3}
\end{equation*}
$$

Notethathe acinymepend onty gnceraised to the first power (and on the constant value of $k$ ). Therefore, radioactive decay is a first-order process (see Section 16.4). The only difference in the case of nuclear decay is that we consider the number of nuclei rather than their concentration.
Half-Life of Radioactive Decay Decay rates are also commonly expressed in terms of the fraction of nuclei that decay over a given time interval. The half-life $\left(\boldsymbol{t}_{1 / 2}\right)$ of a nuclide is the time it takes for half the nuclei present in a sample to decay. The number of nuclei remaining is halved after each half-life. Thus, half-life has the same meaning for a nuclear change as for a chemical change (Section 16.4). Figure 24.4 shows the decay of carbon-14, which has a half-life of 5730 years, in terms of number of ${ }^{14} \mathrm{C}$ nuclei remaining:

$$
{ }_{6}^{14} \mathrm{C} \longrightarrow{ }_{7}^{14} \mathrm{~N}+{ }_{-1}^{0} \beta
$$

We can also consider the half-life in terms of mass of substance. As ${ }^{14} \mathrm{C}$ decays, the mass of ${ }^{14} \mathrm{C}$ decreases while the mass of ${ }^{14} \mathrm{~N}$ increases. If we start with 1.0 g of ${ }^{14} \mathrm{C}$, half that mass of ${ }^{14} \mathrm{C}(0.50 \mathrm{~g})$ will be left after 5730 years, half of that mass $(0.25 \mathrm{~g})$ after another 5730 years, and so on. The activity depends on the number of nuclei, so the activity is halved after each succeeding half-life as well.

We determine the half-life of a nuclear reaction from its rate constant. Rearranging Equation 24.3 and integrating over time gives an expression for finding the number of nuclei remaining after a given time $t, \mathcal{N}_{t}$ :

$$
\begin{equation*}
\ln \frac{\mathcal{N}_{t}}{\mathcal{N}_{0}}=-k t \quad \text { or } \quad \mathcal{N}_{t}=\mathcal{N}_{0} e^{-k t} \quad \text { and } \quad \ln \frac{\mathcal{N}_{0}}{\mathcal{N}_{t}}=k t \tag{24.4}
\end{equation*}
$$

where $\mathcal{N}_{0}$ is the number of nuclei at $t=0$. (Note the similarity to Equation 16.4, p. 700.) To calculate the half-life $\left(t_{1 / 2}\right)$, we set $\mathcal{N}_{t}$ equal to $\frac{1}{2} \mathcal{N}_{0}$ and solve for $t_{1 / 2}$ :

$$
\begin{equation*}
\ln \frac{\mathcal{N}_{0}}{\frac{1}{2} \mathcal{N}_{0}}=k t_{1 / 2} \quad \text { so } \quad t_{1 / 2}=\frac{\ln 2}{k} \tag{24.5}
\end{equation*}
$$

Exactly analogous to the half-life of a first-order chemical change, this half-life is not dependent on the number of nuclei and is inversely related to the decay constant:

$$
\text { large } k \Rightarrow \text { short } t_{1 / 2} \quad \text { and } \quad \text { small } k \Rightarrow \operatorname{long} t_{1 / 2}
$$

The decay constants and half-lives of radioactive nuclides vary over a very wide range, even for the nuclides of a given element (Table 24.5).

## SAMPLE PROBLEM 24.4 Finding the Number of Radioactive Nuclei

PROBLEM Strontium-90 is a radioactive byproduct of nuclear reactors that behaves biologically like calcium, the element above it in Group $2 \mathrm{~A}(2)$. When ${ }^{90} \mathrm{Sr}$ is ingested by mammals, it is found in their milk and eventually in the bones of those drinking the milk. If a sample of ${ }^{90} \mathrm{Sr}$ has an activity of $1.2 \times 10^{12} \mathrm{~d} / \mathrm{s}$, what are the activity and the fraction of nuclei that have decayed after $59 \mathrm{yr}\left(t_{1 / 2}\right.$ of $\left.{ }^{90} \mathrm{Sr}=29 \mathrm{yr}\right)$ ?
PLAN The fraction of nuclei that have decayed is the change in number of nuclei, expressed as a fraction of the starting number. The activity of the sample $(\mathscr{A})$ is proportional to the number of nuclei $(\mathcal{N})$, so we know that

$$
\text { Fraction decayed }=\frac{\mathcal{N}_{0}-\mathcal{N}_{t}}{\mathcal{N}_{0}}=\frac{\mathscr{A}_{0}-\mathscr{A}_{t}}{\mathscr{A}_{0}}
$$

We are given $\mathscr{A}_{0}\left(1.2 \times 10^{12} \mathrm{~d} / \mathrm{s}\right)$, so we find $\mathscr{A}_{t}$ from the integrated form of the first-order rate equation (Equation 24.4), in which $t$ is 59 yr . To solve that equation, we first need $k$, which we can calculate from the given $t_{1 / 2}(29 \mathrm{yr})$.
SOLUTION Calculating the decay constant $k$ :

$$
t_{1 / 2}=\frac{\ln 2}{k} \quad \text { so } \quad k=\frac{\ln 2}{t_{1 / 2}}=\frac{0.693}{29 \mathrm{yr}}=0.024 \mathrm{yr}^{-1}
$$

Applying Equation 24.4 to calculate $\mathscr{A}_{t}$, the activity remaining at time $t$ :

$$
\ln \frac{\mathcal{N}_{0}}{\mathcal{N}_{t}}=\ln \frac{\mathscr{A}_{0}}{\mathscr{A}_{t}}=k t \quad \text { or } \quad \ln \mathscr{A}_{0}-\ln \mathscr{A}_{t}=k t
$$

So, $\quad \ln \mathscr{A}_{t}=-k t+\ln \mathscr{A}_{0}=-\left(0.024 \mathrm{yr}^{-1} \times 59 \mathrm{yr}\right)+\ln \left(1.2 \times 10^{12} \mathrm{~d} / \mathrm{s}\right)$

$$
\ln \mathscr{A}_{t}=-1.4+27.81=26.4
$$

$$
\mathscr{A}_{t}=2.9 \times 10^{11} \mathrm{~d} / \mathrm{s}
$$

(All the data contain two significant figures, so we retained two in the answer.) Calculating the fraction decayed:

$$
\text { Fraction decayed }=\frac{\mathscr{A}_{0}-\mathscr{A}_{t}}{\mathscr{A}_{0}}=\frac{1.2 \times 10^{12} \mathrm{~d} / \mathrm{s}-2.9 \times 10^{11} \mathrm{~d} / \mathrm{s}}{1.2 \times 10^{12} \mathrm{~d} / \mathrm{s}}=0.76
$$

CHECK The answer is reasonable: $t$ is about 2 half-lives, so $\mathscr{A}_{t}$ should be about $\frac{1}{4} \mathscr{A}_{0}$, or about $0.3 \times 10^{12}$; therefore, the activity should have decreased by about $\frac{3}{4}$.

## Table 24.5 Decay Constants (k) and Half-Lives $\left(t_{1 / 2}\right)$ of Beryllium Isotopes

| Nuclide |  | $\boldsymbol{k}$ |
| :--- | :--- | :--- |
| $\boldsymbol{t}_{1 / 2}$ |  |  |
| ${ }_{4}^{7} \mathrm{Be}$ | $1.30 \times 10^{-2} / \mathrm{day}$ | 53.3 days |
| ${ }^{8} \mathrm{Be}$ | $1.0 \times 10^{16} / \mathrm{s}$ | $6.7 \times 10^{-17} \mathrm{~s}$ |
| ${ }_{4}{ }^{4} \mathrm{Be}$ | Stable |  |
| ${ }^{10} \mathrm{Be}$ | $4.3 \times 10^{-7} / \mathrm{yr}$ | $1.6 \times 10^{6} \mathrm{yr}$ |
| ${ }_{4}^{11} 8$ | $5.02 \times 10^{-2} / \mathrm{s}$ | 13.8 s |

The Case of the Shroud of Turin One of the holiest Christian relics is the famed Shroud of Turin. It is a piece of linen that bears a faint image of a man's body and was thought to be the burial cloth used to wrap the body of Jesus Christ. In 1988, the Vatican allowed scientific testing of the cloth by radiocarbon dating. Three labs in Europe and the United States independently measured the ${ }^{12} \mathrm{C} /{ }^{14} \mathrm{C}$ ratio of a $50-\mathrm{mg}$ piece of the linen and determined that the flax from which the cloth was made was grown between 1260 AD and 1390 AD. Despite this evidence, the shroud lost none of its fascination: 10 years later, in 1998, when the shroud was again put on display, about 2 million people lined up to view it.

COMMENT 1. A useful substitution of Equation 24.4 for finding $\mathscr{A}_{t}$, the activity at time $t$, is $\mathscr{A}_{t}=\mathscr{A}_{0} \mathrm{e}^{-k t}$.
2. Another way to find the fraction of activity (or nuclei) remaining incorporates the number of half-lives $\left(t / t_{1 / 2}\right)$. By combining Equations 24.4 and 24.5 and substituting $(\ln 2) / t_{1 / 2}$ for $k$, we obtain

$$
\begin{aligned}
\ln \frac{\mathcal{N}_{0}}{\mathcal{N}_{t}}= & \left(\frac{\ln 2}{t_{1 / 2}}\right) t=\frac{t}{t_{1 / 2}} \ln 2=\ln 2^{t / t_{1 / 2}} \\
& \ln \frac{\mathcal{N}_{t}}{\mathcal{N}_{0}}=\ln \left(\frac{1}{2}\right)^{t / t_{1 / 2}}
\end{aligned}
$$

Inverting the ratio gives
Taking the antilog gives

$$
\text { Fraction remaining }=\frac{\mathcal{N}_{t}}{\mathcal{N}_{0}}=\left(\frac{1}{2}\right)^{t / t / 1 / 2}=\left(\frac{1}{2}\right)^{59 / 29}=0.24
$$

So,

$$
\text { Fraction decayed }=1.00-0.24=0.76
$$

FOLLOW-UP PROBLEM 24.4 Sodium-24 $\left(t_{1 / 2}=15 \mathrm{~h}\right)$ is used to study blood circulation. If a patient is injected with an aqueous solution of ${ }^{24} \mathrm{NaCl}$ whose activity is $2.5 \times 10^{9} \mathrm{~d} / \mathrm{s}$, how much of the activity is present in the patient's body and excreted fluids after 4.0 days?

## Radioisotopic Dating

The historical record fades rapidly with time and virtually disappears for events of more than a few thousand years ago. Much of our understanding of prehistory comes from a technique called radioisotopic dating, which uses radioisotopes to determine the age of an object. The method supplies data in fields as diverse as art history, archeolegy, geology, and paleontology.
AThe echique of radiocarbon aating, forwhich the American chemist Willard F. Libby won the Nobel Prize in chemistry in 1960, is based on measuring the amounts of ${ }^{14} \mathrm{C}$ and ${ }^{12} \mathrm{C}$ in materials of biological origin. The accuracy of the method falls off after about six half-lives of ${ }^{14} \mathrm{C}\left(t_{1 / 2}=5730 \mathrm{yr}\right)$, so it is used to date objects up to about 36,000 years old.

Here is how the method works. High-energy cosmic rays, consisting mainly of protons, enter the atmosphere from outer space and initiate a cascade of nuclear reactions, some of which produce neutrons that bombard ordinary ${ }^{14} \mathrm{~N}$ atoms to form ${ }^{14} \mathrm{C}$ :

$$
{ }_{7}^{14} \mathrm{~N}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{6}^{14} \mathrm{C}+{ }_{1}^{1} \mathrm{p}
$$

Through the competing processes of formation and radioactive decay, the amount of ${ }^{14} \mathrm{C}$ in the atmosphere has remained nearly constant.*

The ${ }^{14} \mathrm{C}$ atoms combine with $\mathrm{O}_{2}$, diffuse throughout the lower atmosphere, and enter the total carbon pool as gaseous ${ }^{14} \mathrm{CO}_{2}$ and aqueous $\mathrm{H}^{14} \mathrm{CO}_{3}{ }^{-}$. They mix with ordinary ${ }^{12} \mathrm{CO}_{2}$ and $\mathrm{H}^{12} \mathrm{CO}_{3}{ }^{-}$, reaching a constant ${ }^{12} \mathrm{C} /{ }^{14} \mathrm{C}$ ratio of about $10^{12} / 1$. Carbon atoms in the $\mathrm{CO}_{2}$ are taken up by plants during photosynthesis, and then taken up and excreted by animals that eat the plants. Thus, the ${ }^{12} \mathrm{C} /{ }^{14} \mathrm{C}$ ratio of a living organism is the same as the ratio in the environment. When an organism dies, however, it no longer absorbs or releases $\mathrm{CO}_{2}$, so the ${ }^{12} \mathrm{C} /{ }^{14} \mathrm{C}$ ratio steadily increases because the amount of ${ }^{14} \mathrm{C}$ decreases as it decays:

$$
{ }_{6}^{14} \mathrm{C} \longrightarrow{ }_{7}^{14} \mathrm{~N}+{ }_{-1}^{0} \beta
$$

The difference between the ${ }^{12} \mathrm{C} /{ }^{14} \mathrm{C}$ ratio in a dead organism and the ratio in living organisms reflects the time elapsed since the organism died.

[^37]

As you saw in Sample Problem 24.4, the first-order rate equation can be expressed in terms of a ratio of actities:go PDF Enhancer

$$
\ln \frac{\mathcal{N}_{0}}{\mathcal{N}_{t}}=\ln \frac{\mathscr{A}_{0}}{\mathscr{A}_{t}}=k t
$$

We use this expression in radiocarbon dating, where $\mathscr{A}_{0}$ is the activity in a living organism and $\mathscr{A}_{t}$ is the activity in the object whose age is unknown. Solving for $t$ gives the age of the object:

$$
\begin{equation*}
t=\frac{1}{k} \ln \frac{\mathscr{A}_{0}}{\mathscr{A}_{t}} \tag{24.6}
\end{equation*}
$$

A useful graphical method in radioisotopic dating shows a plot of the natural logarithm of the specific activity vs. time, which gives a straight line with a slope of $-k$, the negative of the decay constant. Using such a plot and measuring the ${ }^{14} \mathrm{C}$ specific activity of an object, we can determine its age; several examples appear in Figure 24.5. To determine the ages of more ancient objects or of objects that do not contain carbon, different radioisotopes are measured.

## SAMPLE PROBLEM 24.5 Applying Radiocarbon Dating

PROBLEM The charred bones of a sloth in a cave in Chile represent the earliest evidence of human presence at the southern tip of South America. A sample of the bone has a specific activity of 5.22 disintegrations per minute per gram of carbon ( $\mathrm{d} / \mathrm{min} \cdot \mathrm{g}$ ). If the ${ }^{12} \mathrm{C} /{ }^{14} \mathrm{C}$ ratio for living organisms results in a specific activity of $15.3 \mathrm{~d} / \mathrm{min} \cdot \mathrm{g}$, how old are the bones ( $t_{1 / 2}$ of ${ }^{14} \mathrm{C}=5730 \mathrm{yr}$ )?
PLAN We first calculate $k$ from the given $t_{1 / 2}$ ( 5730 yr ). Then we apply Equation 24.6 to find the age $(t)$ of the bones, using the given activities of the bones $\left(\mathscr{A}_{t}=5.22 \mathrm{~d} / \mathrm{min} \cdot \mathrm{g}\right)$ and of a living organism $\left(\mathscr{A}_{0}=15.3 \mathrm{~d} / \mathrm{min} \cdot \mathrm{g}\right)$.
SOLUTION Calculating $k$ for ${ }^{14} \mathrm{C}$ decay:

$$
k=\frac{\ln 2}{t_{1 / 2}}=\frac{0.693}{5730 \mathrm{yr}}=1.21 \times 10^{-4} \mathrm{yr}^{-1}
$$

Figure 24.5 Radiocarbon dating for determining the age of artifacts. The natural logarithms of the specific activities of ${ }^{14} \mathrm{C}$ (activity/g ${ }^{14} \mathrm{C}$ ) for various artifacts are projected onto a line whose slope equals $-k$, the negative of the ${ }^{14} \mathrm{C}$ decay constant. The age (in years) of an artifact is determined from the horizontal axis.

How Old Is the Solar System? By comparing the ratio of ${ }^{238} \mathrm{U}\left(t_{1 / 2}=\right.$ $4.5 \times 10^{9} \mathrm{yr}$ ) to its final decay product, ${ }^{206} \mathrm{~Pb}$, geochemists found that the oldest known surface rocks on Earth-granite in western Greenland-are about 3.7 billion years old. The ratio of ${ }^{238} \mathrm{U} / /^{206} \mathrm{~Pb}$ in meteorites gives 4.65 billion years for the age of the Solar System, and therefore Earth. From this and other isotope ratios, such as ${ }^{40} \mathrm{~K} /{ }^{40} \mathrm{Ar}\left(t_{1 / 2}\right.$ of $\left.{ }^{40} \mathrm{~K}=1.3 \times 10^{9} \mathrm{yr}\right)$ as well as ${ }^{87} \mathrm{Rb} /^{87} \mathrm{Sr}\left(t_{1 / 2}\right.$ of ${ }^{87} \mathrm{Rb}=$ $4.9 \times 10^{10} \mathrm{yr}$ ), Moon rocks collected by Apollo astronauts have been shown to be 4.2 billion years old. They also provide evidence for volcanic activity on the Moon's surface about 3.3 billion years ago, just about the time that, according to these methods, the first organisms were evolving on Earth.

Calculating the age $(t)$ of the bones:

$$
t=\frac{1}{k} \ln \frac{\mathscr{A}_{0}}{\mathscr{A}_{t}}=\frac{1}{1.21 \times 10^{-4} \mathrm{yr}^{-1}} \ln \left(\frac{15.3 \mathrm{~d} / \mathrm{min} \cdot \mathrm{~g}}{5.22 \mathrm{~d} / \mathrm{min} \cdot \mathrm{~g}}\right)=8.89 \times 10^{3} \mathrm{yr}
$$

The bones are about 8900 years old.
CHECK The activity of the bones is between $\frac{1}{2}$ and $\frac{1}{4}$ the activity of a living organism, so the age should be between one and two half-lives ( 5730 to $11,460 \mathrm{yr}$ ).
FOLLOW-UP PROBLEM 24.5 A sample of wood from an Egyptian mummy case has a specific activity of $9.41 \mathrm{~d} / \mathrm{min} \cdot \mathrm{g}$. How old is the case?

## Section Summary

Ionization and scintillation counters measure the number of emissions from a radioactive sample. - The decay rate (activity) of a sample is proportional to the number of radioactive nuclei. Nuclear decay is a first-order process, so the half-life is a constant for each nuclide. • Radioisotopic methods, such as ${ }^{14} \mathrm{C}$ dating, determine the ages of objects by measuring the ratio of specific isotopes in the sample.

### 24.3 NUCLEAR TRANSMUTATION: INDUCED CHANGES IN NUCLEI

The alchemists' dream of changing base metals into gold was never realized, but in the early $20^{\text {th }}$ century, nuclear physicists found that they could change one element into another. Research into nuclear transmutation, the induced conversion of one nucleus into another, was closely linked with research into atomic structure and led to the discovery of the neutron and to the production of artificial radioisetepes Late high-mergh bophardment of nuclei in particle accelerators began a scientific endeavor, which continues to this day, of creating many new nuclides and a growing number of new elements.

## Early Transmutation Experiments; Nuclear Shorthand Notation

The first recognized transmutation occurred in 1919, when Ernest Rutherford showed that $\alpha$ particles emitted from radium bombarded atmospheric nitrogen to form a proton and oxygen-17:

$$
{ }_{7}^{14} \mathrm{~N}+{ }_{2}^{4} \alpha \longrightarrow{ }_{1}^{1} \mathrm{p}+{ }_{8}^{17} \mathrm{O}
$$

By 1926, experimenters had found that $\alpha$ bombardment transmuted most elements with low atomic numbers to the next higher element, with ejection of a proton.

A shorthand notation used specifically for nuclear transmutation reactions shows the reactant (target) nucleus to the left and the product nucleus to the right of a set of parentheses, within which a comma separates the projectile particle from the ejected particle(s):
reactant nucleus (particle in, particle(s) out) product nucleus

Using this notation, the previous reaction is ${ }^{14} \mathrm{~N}(\alpha, \mathrm{p}){ }^{17} \mathrm{O}$.
An unexpected finding in a transmutation experiment led to the discovery of the neutron. When lithium, beryllium, and boron were bombarded with $\alpha$ particles, they emitted highly penetrating radiation that could not be deflected by a magnetic or electric field. Unlike $\gamma$ radiation, these emissions were massive enough to eject protons from the substances they penetrated. In 1932, James Chadwick, a student of Rutherford, proposed that these emissions consisted of neutral particles with a mass similar to that of a proton, and he named them neutrons. Chadwick received the Nobel Prize in physics in 1935 for his discovery.

In 1933, Irene and Frederic Joliot-Curie (see photo), daughter and son-in-law of Marie and Pierre Curie, created the first artificial radioisotope, phosphorus-30.

When they bombarded aluminum foil with $\alpha$ particles, phosphorus- 30 and neutrons were formed:

$$
{ }_{13}^{27} \mathrm{Al}+{ }_{2}^{4} \alpha \longrightarrow{ }_{0}^{1} \mathrm{n}+{ }_{15}^{30} \mathrm{P} \quad \text { or } \quad{ }^{27} \mathrm{Al}(\alpha, \mathrm{n}){ }^{30} \mathrm{P}
$$

Since then, other techniques for producing artificial radioisotopes have been developed. In fact, the majority of the nearly 1000 known radionuclides have been produced artificially.

## Particle Accelerators and the Transuranium Elements

During the 1930s and 1940s, researchers probing the nucleus bombarded elements with neutrons, $\alpha$ particles, protons, and deuterons (nuclei of the stable hydrogen isotope deuterium, ${ }^{2} \mathrm{H}$ ). Neutrons are especially useful as projectiles because they have no charge and thus are not repelled as they approach a target nucleus. The other particles are all positive, so early researchers found it difficult to give them enough energy to overcome their repulsion by the target nuclei. Beginning in the 1930s, however, particle accelerators were invented to impart high kinetic energies to particles by placing them in an electric field, usually in combination with a magnetic field. In the simplest and earliest design, protons are introduced at one end of a tube and attracted to the other end by a potential difference.

A major advance was the linear accelerator, a series of separated tubes of increasing length that, through a source of alternating voltage, change their charge from positive to negative in synchrony with the movement of the particle through them (Figure 24.6).

A proton, for example, exits the first tube just when that tube becomes positive and the next tube negative. Repelled by the first tube and attracted by the second, the proton accelerates across the gap between them. The process is performed in stages to achieve high particle energies without having to apply a single high voltage. A 40-ft linear accelerator with 46 tubes, built in California after World War II, accelerated protons to speeds several million times faster than earlier accelerators.

The cyclotron (Figure 24.7), invented by E. O. Lawrence in 1930, applies the principle of the linear accelerator but uses electromagnets to give the particle a spiral path, thus saving space. The magnets lie within an evacuated chamber above and below two "dees," open, D-shaped electrodes that act like the tubes in the linear design. The particle is accelerated as it passes from one dee, which is momentarily positive, to the other, which is momentarily negative. Its speed and radius increase until it is deflected toward the target nucleus.

Figure 24.6 Schematic of a linear
accelerator. The voltage of each tubular section is alternated, so that the positively charged particle (a proton here) is repelled from the section it is leaving and attracted to the section it is entering. As a result, the particle's speed is continually increased.

Figure 24.7 Schematic of a cyclotron accelerator.

The Powerful Bevatron The bevatron, used to study the physics of high-energy particle collisions, includes a linear section and a synchrotron section. The instrument at the Lawrence Berkeley Laboratory in California increases the kinetic energy of the particles by a factor of more than 6 billion. A beam of $10^{10}$ protons makes more than 4 million revolutions, a distance of 300,000 miles, in 1.8 s , attaining a final speed about $90 \%$ of the speed of light! Even more powerful accelerators are in use at the Fermi Lab near Chicago and at CERN, near Geneva, Switzerland.

Naming the Transuranium Elements The last naturally occurring element was named after Uranus, thought at the time to be the outermost planet, so the first two artificial elements were named after the more recently discovered Neptune and Pluto. The next few elements were named after famous scientists, as in curium, and places, as in americium. But conflicting claims of discovery by scientists in the U.S. and Soviet Union led to controversies about names for some of the elements. To provide interim names until the disputes could be settled, the International Union of Pure and Applied Chemistry (IUPAC) adopted a system that uses the atomic number as the basis for a Latin name. Thus, for example, element 104 was named unnilquadium (un $=1$, nil $=$ 0 , quad $=4$, ium $=$ metal suffix), with the symbol Unq. After much compromise, the IUPAC has finalized these names: 104, rutherfordium (Rf); 105, dubnium (Db); 106, seaborgium (Sg); 107, bohrium (Bh); 108, hassium (Hs); 109, meitnerium (Mt); 110, darmstadtium (Ds), and 111, roentgenium (Rg). Elements with atomic numbers 112 and higher have not yet been named.

Table 24.6 Formation of Some Transuranium Nuclides*

Reaction

| ${ }_{94}^{239} \mathrm{Pu}$ | $+$ | $2{ }_{0}^{1} \mathrm{n}$ | $\longrightarrow$ | ${ }_{95}^{241} \mathrm{Am}$ | $+$ | ${ }_{-1}^{0} \beta$ | 432 yr |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| ${ }_{94}^{239} \mathrm{Pu}$ | + | ${ }_{2}^{4} \alpha$ | $\longrightarrow$ | ${ }_{96}^{242} \mathrm{Cm}$ | + | ${ }_{0}^{1} \mathrm{n}$ | 163 days |
| ${ }_{95}^{241} \mathrm{Am}$ | + | ${ }_{2}^{4} \alpha$ | $\longrightarrow$ | ${ }_{97}^{243} \mathrm{Bk}$ | + | $2{ }_{0}^{1} \mathrm{n}$ | 4.5 h |
| ${ }_{96}^{242} \mathrm{Cm}$ | $+$ | ${ }_{2}^{4} \alpha$ | $\longrightarrow$ | ${ }_{98}^{245} \mathrm{Cf}$ | + | ${ }_{0}^{1} \mathrm{n}$ | 45 min |
| ${ }^{253}$ Es | + | ${ }_{2}^{4} \alpha$ | $\longrightarrow$ | ${ }_{101}^{256} \mathrm{Md}$ | + | ${ }_{0}^{1} \mathrm{n}$ | 76 min |
| ${ }_{95}^{243} \mathrm{Am}$ | $+$ | ${ }_{8}^{18} \mathrm{O}$ | $\longrightarrow$ | ${ }_{103}^{256} \mathrm{Lr}$ | + | $5{ }_{0}^{1} \mathrm{n}$ | 28 s |

*Like chemical reactions, nuclear reactions may occur in several steps. For example, the first reaction here is actually an overall process that occurs in three steps:
(1) ${ }_{94}^{239} \mathrm{Pu}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{94}^{240} \mathrm{Pu}$
(2) ${ }_{94}^{240} \mathrm{Pu}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{94}^{241} \mathrm{Pu}$
(3) ${ }_{94}^{241} \mathrm{Pu} \longrightarrow{ }_{95}^{241} \mathrm{Am}+{ }_{-1}^{0} \beta$

The synchrotron uses a synchronously increasing magnetic field to make the particle's path circular rather than spiral.

Scientists use accelerators for many applications, from producing radioisotopes used in medical applications to studying the fundamental nature of matter. Perhaps the most specific application for chemists is the synthesis of transuranium elements, those with atomic numbers higher than uranium, the heaviest naturally occurring element. Some reactions that were used to form several of these elements appear in Table 24.6. The transuranium elements include the remaining actinides $(Z=93$ to 103$)$, in which the $5 f$ sublevel is being filled, and the elements in the fourth transition series $(Z=104$ to 112$)$, in which the $6 d$ sublevel is being filled.)

## Apago PDF Enhancer Section Summary

One nucleus can be transmuted to another through bombardment with high-energy particles. - Accelerators increase the kinetic energy of particles in nuclear bombardment experiments and are used to produce transuranium elements and radioisotopes for medical use.

### 24.4 THE EFFECTS OF NUCLEAR RADIATION ON MATTER

In 1986, an accident at the Chernobyl nuclear facility in the former Soviet Union released radioactivity that, according to the World Health Organization, will cause thousands of cancer deaths. In the same year, isotopes used in medical treatment emitted radioactivity that prevented thousands of cancer deaths. In this section and Section 24.5, we examine radioactivity's harmful and beneficial effects.

The key to both of these effects is that nuclear changes cause chemical changes in surrounding matter. In other words, even though the nucleus of an atom may undergo a reaction with little or no involvement of the atom's electrons, the emissions from that reaction do affect the electrons of nearby atoms.

Virtually all radioactivity causes ionization in surrounding matter, as the emissions collide with atoms and dislodge electrons:

$$
\text { Atom } \xrightarrow{\text { ionizing radiation }} \text { ion }^{+}+\mathrm{e}^{-}
$$

From each ionization event, a cation and a free electron result, and the number of such cation-electron pairs produced is directly related to the energy of the incoming ionizing radiation.

Many applications of ionizing radiation depend not only on the ionizing event itself, but also on secondary processes. For example in a Geiger-Müller counter,
the free electron of the cation-electron pair often collides with another atom, which ejects a second electron, and in a scintillation counter, the inital ionization eventually results in emission of light (see Tools of the Laboratory essay, p. 1075). In nuclear power plants (Section 24.7), the inital process as well as several secondary processes cause the heating that makes steam to create electricity.

## Effects of Ionizing Radiation on Living Matter

Ionizing radiation has a destructive effect on living tissue, and if the ionized atom is part of a key biological macromolecule or cell membrane, the results can be devastating to the cell and perhaps the organism.

The danger from a radionuclide depends on three factors: the type of radiation, its half-life, and, most importantly, its biochemical behavior. For example, both ${ }^{235} \mathrm{U}$ and ${ }^{239} \mathrm{Pu}$ emit $\alpha$ particles and have long half-lives, but uranium is rapidly excreted by the body, wheras plutonium behaves like calcium and, thus, is incorporated into bones and teeth. One of the most dangerous radionuclides is ${ }^{90} \mathrm{Sr}^{2+}$ (formed during a nuclear explosion) because it behaves very similarly to $\mathrm{Ca}^{2+}$ and is absorbed strongly by bones. Let's first see how to measure radiation dose and then delve into various aspects of these factors in more detail.

Units of Radiation Dose and Its Effects To measure the effects of ionizing radiation, we need a unit for radiation dose. Units of radioactive decay, such as the becquerel and curie, measure the number of decay events in a given time but not their energy or absorption by matter. The number of cation-electron pairs produced in a given amount of living tissue is a measure of the energy absorbed by the tissue. The SI unit for such energy absorption is the gray (Gy); it is equal to 1 joule of energy absorbed per kilogram of body tissue: 1 Gy $=1 \mathrm{~J} / \mathrm{kg}$. A more widely used unit is the rad gadiationeabsorbed doserwhich is equato 0.01 Gy :

$$
1 \mathrm{rad}=0.01 \mathrm{~J} / \mathrm{kg}=0.01 \mathrm{~Gy}
$$

To measure actual tissue damage, we must account for differences in the strength of the radiation, the exposure time, and the type of tissue. To do this, we multiply the number of rads by a relative biological effectiveness (RBE) factor, which depends on the effect of a given type of radiation on a given tissue or body part. The product is the rem (roentgen equivalent for man), the unit of radiation dosage equivalent to a given amount of tissue damage in a human:

$$
\text { no. of rems }=\text { no. of rads } \times \mathrm{RBE}
$$

Doses are often expressed in millirems ( $10^{-3}$ rem). The SI unit for dosage equivalent is the sievert ( $\mathbf{S v}$ ). It is defined in the same way as the rem but with absorbed dose in grays; thus, 1 rem $=0.01 \mathrm{~Sv}$.

Penetrating Power of Emissions The effect on living tissue of a radiation dose depends on the penetrating power and ionizing ability of the radiation. Figure 24.8 depicts the differences in penetrating power of the three common emissions. Note, in general, that penetrating power is inversely related to the mass, charge, and energy of the emission. In other words, if a particle interacts strongly with matter, it penetrates only slightly, and vice versa:

- $\alpha$ Particles. Alpha particles are massive and highly charged, which means that they interact with matter most strongly of the three common types of emissions. As a result, they penetrate so little that a piece of paper, light clothing, or the outer layer of skin can stop $\alpha$ radiation from an external source. Internally, however, such as from ingestion, an $\alpha$ emitter can cause grave localized damage through extensive ionization.

Figure 24.8 Penetrating power of radioactive emissions. Penetrating power is often measured in terms of the depth of water that stops $50 \%$ of the incoming radiation. (Water is the main component of living tissue.) Alpha particles, with the highest mass and charge, have the lowest penetrating power, and $\gamma$ rays have the highest. (Average values of actual penetrating distances are shown.)

A Tragic Way to Tell Time in the Dark In the early $20^{\text {th }}$ century, wristwatch and clock dials were painted by hand with paint containing radium so they would glow in the dark. To write numbers clearly, the young women hired to apply the paint "tipped" fine brushes repeatedly between their lips. Small amounts of ingested ${ }^{226} \mathrm{Ra}^{2+}$ were incorporated into the bones of the women, along with normal $\mathrm{Ca}^{2+}$, which led to numerous cases of bone fracture and jaw cancer.

A Tale of Two Agents The relative danger from $\alpha$ - and $\beta^{-}$-emitting radionuclides is dramatically revealed in the poisoning of two former Russian intelligence agents. In 1957, an agent was poisoned by thallium-204, a $\beta^{-}$emitter, but he survived because $\beta^{-}$particles do relatively little radiation damage. In contrast, in 2006, another agent was poisoned with polonium-210, an $\alpha$ emitter, and died in three weeks because of the much greater radiation damage. The clandestine nature of this action was enhanced by the fact that ${ }^{210}$ Po emits few $\gamma$ rays, so it cannot be detected by airport and hotel screening devices.

- Beta Particles and Positrons. Beta particles $\left(\beta^{-}\right)$and positrons $\left(\beta^{+}\right)$have less charge and much less mass than $\alpha$ particles, so they interact less strongly with matter. Even though a given particle has less chance of causing ionization, a $\beta^{-}$(or $\beta^{+}$) emitter is a more destructive external source because the particles penetrate deeper. Specialized heavy clothing or a thick $(0.5 \mathrm{~cm})$ piece of metal is required to stop these particles.
- $\gamma$ Rays. Neutral, massless $\gamma$ rays interact least with matter and, thus, penetrate most. A block of lead several inches thick is needed to stop them. Therefore, an external $\gamma$ ray source is the most dangerous because the energy can ionize many layers of living tissue.

A more variable case occurs with emission of neutrons, which are neutral and massive. Outside a nucleus, neutrons decay with a half-life of 10.6 min into a proton and an electron (and an antineutrino). With energies ranging from very low to very high, they may be scattered or captured by interaction with nuclei.

Molecular Interactions How does the damage take place on the molecular level? When ionizing radiation interacts with a molecule, it causes the loss of an electron from a bond or a lone pair. The resulting charged species go on to form free radicals, molecular or atomic species with one or more unpaired electrons. As you've seen several times in earlier chapters, species with lone electrons are very reactive. They form electron pairs by attacking bonds in other molecules, sometimes forming more free radicals.

When $\gamma$ radiation strikes biological tissue, for instance, the most likely molecule to absorb it is water, which forms an electron and a water ion-radical:

$$
\mathrm{H}_{2} \mathrm{O}+\gamma \longrightarrow \mathrm{H}_{2} \mathrm{O}^{+}+\mathrm{e}^{-}
$$

The $\mathrm{H}_{2} \mathrm{O}^{+}$and $\mathrm{e}^{-}$collide with more water to form more free radicals:

These free radicals go on to attack more water molecules and surrounding biomolecules, whose bonding and structure, as you know, are intimately connected with their function (Section 15.6).

The double bonds in membrane lipids are particularly susceptible to freeradical attack:

$$
\mathrm{H} \cdot+\mathrm{RCH}=\mathrm{CHR}^{\prime} \longrightarrow \mathrm{RCH}_{2}-\dot{\mathrm{C}} \mathrm{HR}^{\prime}
$$

In this reaction, one electron of the $\pi$ bond forms a $\mathrm{C}-\mathrm{H}$ bond between one of the double-bonded carbons and the $\mathrm{H}^{\cdot}$, and the other electron resides on the other carbon to form a free radical. Changes to lipid structure cause changes in membrane fluidity and other damage that, in turn, result in leakage through cell membranes and destruction of the protective fatty tissue around organs. Changes to critical bonds in enzymes lead to their malfunction as catalysts of metabolic reactions. Changes in the nucleic acids and proteins that govern the rate of cell division can cause cancer. Genetic damage and mutations may occur when bonds in the DNA of sperm and egg cells are altered by free radicals.

## Sources of Ionizing Radiation

We are continuously exposed to ionizing radiation from natural and artificial sources (Table 24.7). Indeed, life evolved in the presence of natural ionizing radiation, called background radiation. The same radiation that alters bonds in DNA and causes harmful mutations also causes beneficial mutations that, over evolutionary time, allow species to change.

Background radiation has several sources. One source is cosmic radiation, which increases with altitude because of decreased absorption by the atmosphere. Thus, people in Denver absorb twice as much cosmic radiation as people in Los

## Table 24.7 Typical Radiation Doses from Natural and Artificial Sources

$\leq 1 \mathrm{rad} / \mathrm{film}$
Locally $\leq 10,000 \mathrm{rad}$
$\sim 1$ mrem

100 - $200 \mathrm{mrem} / \mathrm{yr}$

Angeles; even a jet flight involves measurable absorption. The sources of most background radiation are thorium and uranium minerals present in rocks and soil. Radon, the heaviest noble gas [Group $8 \mathrm{~A}(18)$ ], is a radioactive product of uranium and thorium decay. Its concentration in the air we breathe is associated with certain common building materials and types of local soil and rocks. Its decay products cause most of the damage. About 150 g of $\mathrm{K}^{+}$ions is dissolved in the water in the tissues of an average adult, and $0.0118 \%$ of these ions are radioactive ${ }^{40} \mathrm{~K}$. The presence of these substances and of atmospheric ${ }^{14} \mathrm{CO}_{2}$ makes all food, water, clothing, and building materials slightly radioactive.

The largest artificial source of radiation, and the one that is easiest to control, is from medical diagnostic techniques, especially x-rays. The radiation dosage from nuclear testing and radioactive waste disposal is miniscule for most people, but exposures for those living near test sites or disposal areas may be much higher.

## Assessing the Risk from lonizing Radiation

How much radiation is too much? To approach this question, we must ask several others: How strong is the exposure? How long is the exposure? Which tissue is exposed? Are children affected? One reason we lack clear data to answer these questions is that scientific ethical standards forbid the intentional exposure of humans in an experimental setting. However, accidentally exposed radiation workers and Japanese atomic bomb survivors have been studied extensively.
 the largest noble gas, is a natural decay product of uranium. Therefore, the uranium content of the local soil and rocks is critical, but radon occurs everywhere in varying concentrations. It exists in especially high amounts in cinder blocks made from the waste ash sold by power plants that burn coal high in uranium. Radon itself serves as the volatile medium for entering the body, where it poses a serious potential hazard as it decays to radioactive nuclides of $\mathrm{Po}, \mathrm{Pb}$, and Bi , through $\alpha, \beta^{-}$, and $\gamma$ emission. The emissions damage lung tissue, and the heavymetal atoms formed aggravate the problem. Recent EPA estimates indicate that radon contributes to $15 \%$ of annual lung cancer deaths.

Modeling Radiation Risk There are two current models of effect vs. dose. The linear response model proposes that radiation effects, such as cancer risks, accumulate over time regardless of dose and that populations should not be exposed to any radiation above background levels. The $S$-shaped response model implies there is a threshhold above which the effects are more significant: very low risk at low dose and high risk at high dose. If the linear model is more accurate, we should limit all excess exposure, but this would severely restrict medical diagnosis, military testing, and energy production.

Table 24.8 Acute Effects of a Single Dose of Whole-Body Irradiation

| Dose (rem) | Effect | Lethal Dose |  |
| :---: | :---: | :---: | :---: |
|  |  | Population (\%) | No. of Days |
| 5-20 | Possible late effect; possible chromosomal aberrations | - | - |
| 20-100 | Temporary reduction in white blood cells | - | - |
| 50+ | Temporary sterility in men ( $100+$ rem $=1$-yr duration $)$ | - | - |
| 100-200 | "Mild radiation sickness": vomiting, diarrhea, tiredness in a few hours <br> Reduction in infection resistance Possible bone growth retardation in children | - | - |
| $300+$ | Permanent sterility in women | - | - |
| 500 | "Serious radiation sickness": marrow/intestine destruction | 50-70 | 30 |
| 400-1000 | Acute illness, early deaths | 60-95 | 30 |
| $3000+$ | Acute illness, death in hours to days | 100 | 2 |

Table 24.8 summarizes the immediate tissue effects on humans of an acute single dose of ionizing radiation to the whole body. The severity of the effects
 ulation within a month.

Most data come from laboratory animals, whose biological systems may differ greatly from ours. Nevertheless, studies with mice and dogs show that lesions and cancers appear after massive whole-body exposure, with rapidly dividing cells affected first. In an adult animal, these are cells of the bone marrow, organ linings, and reproductive organs, but many other tissues are affected in an immature animal or fetus. Studies in both animals and humans show an increase in the incidence of cancer from either a high, single exposure or a low, chronic exposure.

Reliable data on genetic effects are few. Pioneering studies on fruit flies show a linear increase in genetic defects with both dose and exposure time. However, in the mouse, whose genetic system is obviously much more similar to ours than is the fruit fly's, a total dose given over a long period created one-third as many genetic defects as the same dose given over a short period. Therefore, rate of exposure is a key factor. The children of atomic bomb survivors show higher-than-normal childhood cancer rates, implying that their parents' reproductive systems were affected.

## Section Summary

All radioactive emissions cause ionization. - The effect of ionizing radiation on living matter depends on the quantity of energy absorbed and the extent of ionization in a given type of tissue. Radiation dose for the human body is measured in rem. • Ionization forms free radicals, some of which proliferate and destroy biomolecular function. - All organisms are exposed to varying quantities of natural ionizing radiation. • Studies show that either a large acute dose or a chronic small dose is harmful.

### 24.5 APPLICATIONS OF RADIOISOTOPES

Our ability to detect minute amounts of radioisotopes makes them powerful tools for studying processes in biochemistry, medicine, materials science, environmental studies, and many other scientific and industrial fields. Such uses depend on the fact that isotopes of an element exhibit very similar chemical and physical behavior. In other words, except for having a less stable nucleus, a radioisotope has nearly the same chemical properties as a nonradioactive isotope of that element.* For example, the fact that ${ }^{14} \mathrm{CO}_{2}$ is utilized by a plant in the same way as ${ }^{12} \mathrm{CO}_{2}$ forms the basis of radiocarbon dating.

## Radioactive Tracers

Just think how useful it could be to follow a substance through a complex process or from one region of a system to another. A tiny amount of a radioisotope mixed with a large amount of the stable isotope can act as a tracer, a chemical "beacon" emitting radiation that signals the presence of the substance.
Reaction Pathways Tracers help us choose from among possible reaction pathways. One well-studied example is the reaction between periodate and iodide ions:

$$
\mathrm{IO}_{4}^{-}(a q)+2 \mathrm{I}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{I}_{2}(s)+\mathrm{IO}_{3}^{-}(a q)+2 \mathrm{OH}^{-}(a q)
$$

Is $\mathrm{IO}_{3}{ }^{-}$the result of $\mathrm{IO}_{4}^{-}$reduction or $\mathrm{I}^{-}$oxidation? When we add "cold" (nonradioactive) $\mathrm{IO}_{4}^{-}$to a solution of $\mathrm{I}^{-}$that contains some "hot" (radioactive, indicated in red) ${ }^{131} \mathrm{I}^{-}$, we find that the $\mathrm{I}_{2}$ is radioactive, not the $\mathrm{IO}_{3}{ }^{-}$:

$$
\mathrm{IO}_{4}^{-}(a q)+2^{131} \mathrm{I}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow{ }^{131} \mathrm{I}_{2}(s)+\mathrm{IO}_{3}^{-}(a q)+2 \mathrm{OH}^{-}(a q)
$$

These results show that $\mathrm{IO}_{3}{ }^{-}$forms through the reduction of $\mathrm{IO}_{4}{ }^{-}$, and that $\mathrm{I}_{2}$ forms through the oxidation of $\mathrm{I}^{-}$. To confirm this pathway we add $\mathrm{IO}_{4}{ }^{-}$containing some ${ }^{131} \mathrm{IO}_{4}{ }^{-}$to a solution of ${ }^{-1}$. As we expected, the $\mathrm{IO}_{3}^{\text {a. is radioac- }}$ tive, not the $\mathrm{I}_{2}$ :

$$
{ }^{131} \mathrm{IO}_{4}^{-}(a q)+2 \mathrm{I}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{I}_{2}(s)+{ }^{131} \mathrm{IO}_{3}^{-}(a q)+2 \mathrm{OH}^{-}(a q)
$$

Thus, tracers act like "handles" we can "hold" to follow the changing reactants.
Far more complex pathways can be followed with tracers as well. The photosynthetic pathway, the most essential and widespread metabolic process on Earth, in which energy from sunlight is used to form the chemical bonds of glucose, has an overall reaction that looks quite simple:

$$
6 \mathrm{CO}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l) \xrightarrow[\text { chlorophyll }]{\text { light }} \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(s)+6 \mathrm{O}_{2}(g)
$$

However, the actual process is extremely complex: 13 enzyme-catalyzed steps are required to incorporate each C atom from $\mathrm{CO}_{2}$, so the six $\mathrm{CO}_{2}$ molecules incorporated to form a molecule of $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$ require six repetitions of the pathway. Melvin Calvin and his coworkers took seven years to determine the pathway, using ${ }^{14} \mathrm{C}$ in $\mathrm{CO}_{2}$ as the tracer and paper chromatography as the means of separating the products formed after different times of light exposure. Calvin won the Nobel Prize in chemistry in 1961 for this remarkable achievement.

Tracers are used in many studies of biological function. Recently, future opportunities for living in outer space have required answers to new questions. In an animal study of red blood cell loss during extended space flight, blood plasma

[^38]volume was measured with ${ }^{125}$ I-labeled albumin (a blood protein), and red blood cells labeled with ${ }^{51} \mathrm{Cr}$ as a trace substitute for Fe were used to assess survival of blood cells. In another study, blood flow in skin under long periods of microgravity was monitored using injected ${ }^{133} \mathrm{Xe}$.

Material Flow Tracers are used in studies of solid surfaces and the flow of materials. Metal atoms hundreds of layers deep within a solid have been shown to exchange with metal ions from the surrounding solution within a matter of minutes. Chemists and engineers use tracers to study material movement in semiconductor chips, paint, and metal plating, in detergent action, and in the process of corrosion, to mention just a few of many applications.

Hydrologic engineers use tracers to study the volume and flow of large bodies of water. By following radionuclides that formed during atmospheric nuclear bomb tests $\left({ }^{3} \mathrm{H}\right.$ in $\mathrm{H}_{2} \mathrm{O},{ }^{90} \mathrm{Sr}^{2+}$, and $\left.{ }^{137} \mathrm{Cs}^{+}\right)$, scientists have mapped the flow of water from land to lakes and streams to oceans. They also use tracers to study the surface and deep ocean currents that circulate around the globe, as well as the mechanisms of hurricane formation and the mixing of the troposphere and stratosphere. Industries employ tracers to study material flow during the manufacturing process, such as the flow of ore pellets in smelting kilns, the paths of wood chips and bleach in paper mills, the diffusion of fungicide into lumber, and in a particularly important application, the porosity and leakage of oil and gas wells in geological formations.

Activation Analysis Another use of tracers is in neutron activation analysis (NAA). In this method, neutrons bombard a nonradioactive sample, converting a small fraction of its atoms to radioisotopes, which exhibit characteristic decay patterns, such as $\gamma$-ray spectra, that reveal the elements present. Unlike chemical anfysis, $9 A A$ leavesthe 5ample aitulleinfact, so the method can be used to determine the composition of a valuable object or a very small sample. For example, a painting thought to be a $16^{\text {th }}$-century Dutch masterpiece was shown through NAA to be a $20^{\text {th }}$-century forgery, because a microgram-sized sample of its pigment contained much less silver and antimony than the pigments used by the Dutch masters. Forensic chemists use NAA to detect traces of ammunition on a suspect's hand or traces of arsenic in the hair of a victim of poisoning.

Automotive engineers employ NAA and $\gamma$-ray detectors to measure friction and wear of moving parts without having to take the engine apart. For example, when a steel surface that has been neutron-activated to form some radioactive ${ }^{59} \mathrm{Fe}$ moves against a second steel surface, the amount of radioactivity on the second surface indicates the amount of material rubbing off. The radioactivity appearing in a lubricant placed between the surfaces can demonstrate the lubricant's ability to reduce wear.

Medical Diagnosis The largest use of radioisotopes is in medical science. In fact, over $25 \%$ of U.S. hospital admissions are for diagnoses based on data from radioisotopes. Tracers with half-lives of a few minutes to a few days are employed to observe specific organs and body parts. For example, a healthy thyroid gland incorporates dietary $\mathrm{I}^{-}$into iodine-containing hormones at a known rate. To assess thyroid function, the patient drinks a solution containing a trace amount of $\mathrm{Na}^{131} \mathrm{I}$, and a scanning monitor follows the uptake of ${ }^{131} \mathrm{I}^{-}$into the thyroid (Figure 24.9A). Technetium-99 $(Z=43)$ is also used for imaging the thyroid (Figure 24.9 B ), as well as the heart, lungs, and liver. Technetium does not occur naturally, so the radioisotope (actually a metastable form, ${ }^{99 \mathrm{~m}} \mathrm{Tc}$ ) is prepared from radioactive molybdenum just before use:

$$
{ }_{42}^{99} \mathrm{Mo} \longrightarrow{ }_{43}^{99 \mathrm{~m}} \mathrm{Tc}+{ }_{-1}^{0} \beta
$$

Figure 24.9 The use of radioisotopes to image the thyroid gland. Thyroid scanning is used to assess nutritional deficiencies, inflammation, tumor growth, and other thyroid-related ailments. A, In ${ }^{131}$ I scanning, the thyroid gland absorbs ${ }^{131} I^{-}$ions, which undergo $\beta^{-}$decay that exposes a photographic film. The asymmetric image indicates disease. $B, A^{99}$ Tc scan of a healthy thyroid.

Tracers are also used to measure physiological processes, such as blood flow. The rate at which the heart pumps blood, for example, can be observed by injecting ${ }^{59} \mathrm{Fe}$, which becomes incorporated into the hemoglobin of blood cells. Several radioisotopes used in medical diagnosis are listed in Table 24.9.

Positron-emission tomography (PET) is a powerful imaging method for observing brain structure and function. A biological substance is synthesized with one of its atoms replaced by an isotope that emits positrons. The substance is injected into a patient's bloodstream, from which it is taken up into the brain. The isotope emits positrons, each of which annihilates a nearby electron. In this process, two $\gamma$ photons are emitted simultaneously $180^{\circ}$ from each other:

## 

An array of detectors around the patient's head pinpoints the sites of $\gamma$ emission, and the image is analyzed by computer. Two of the isotopes used are ${ }^{15} \mathrm{O}$, injected as $\mathrm{H}_{2}{ }^{15} \mathrm{O}$ to measure blood flow, and ${ }^{18} \mathrm{~F}$ bonded to a glucose analog to measure glucose uptake, which is an indicator of energy metabolism. Among many fascinating PET findings are those that show how changes in blood flow and glucose uptake accompany normal or abnormal brain activity (Figure 24.10). In a recent nonmedical development, substances incorporating ${ }^{11} \mathrm{C}$ and ${ }^{15} \mathrm{O}$ are being investigated using PET to learn how molecules interact with and move along the surface of a catalyst.

Figure 24.10 PET and brain activity. These PET scans show brain activity in a normal person (left) and in a patient with Alzheimer's disease (right). Red and yellow indicate relatively high activity within a region.

Table 24.9 Some Radioisotopes Used as Medical Tracers

| Isotope | Body Part <br> or Process |
| :--- | :--- |
| ${ }^{11} \mathrm{C},{ }^{18} \mathrm{~F}$, | PET studies of <br> brain, heart |

Animation: Nuclear Medicine

Figure 24.11 The increased shelf life of irradiated food.

## Additional Applications of Ionizing Radiation

To be used as a tracer, a radioisotope need only emit radiation that can be detected. Many other uses of radioisotopes depend on ionizing radiation of higher energy.

Cancer cells divide more rapidly than normal cells, so radioisotopes that interfere with cell division kill more cancer cells than normal ones. Implants of ${ }^{198} \mathrm{Au}$ or of ${ }^{90} \mathrm{Sr}$, which decays to the $\gamma$-emitting ${ }^{90} \mathrm{Y}$, have been used to destroy pituitary and breast tumor cells, and $\gamma$ rays from ${ }^{60} \mathrm{Co}$ have been used to destroy tumors of the brain and other body parts.

Irradiation of food increases shelf life by killing microorganisms that cause rotting or spoilage (Figure 24.11), but the practice is quite controversial. Advocates point to the benefits of preserving fresh foods, grains, and seeds for long periods, whereas opponents suggest that irradiation might lower the food's nutritional content or produce harmful byproducts. Irradiation also provides a way to destroy newer, more resistant bacterial strains that survive the increasing use of the more common antibiotics in animal feed. The United Nations has approved irradiation for potatoes, wheat, chicken, and strawberries, and, in 2003, the U.S. Food and Drug Administration approved it as well.

Ionizing radiation has been used to control harmful insects. Captured males are sterilized by radiation and released to mate, thereby reducing the number of offspring. This method has been used to control the Mediterranean fruit fly in California and disease-causing insects, such as the tsetse fly and malarial mosquito, in other parts of the world.

A recent, nonharmful use of ionizing radiation relies on its secondary processes. Most spacecraft use solar energy to provide power for instruments. In deep-space missions, when solar energy is too weak, however, a radioisotope heater unit (RHU) is used. It consists of $\mathrm{a}^{238} \mathrm{PuO}_{2}$ fuel pellet the size of a pencitcraserchat is clad withinarmintitayeredegraphite and metal shell a little smaller than a flashlight battery. The whole RHU weighs only 40 g .

## Section Summary

Radioisotopic tracers have been used to study reaction mechanisms, material flow, elemental composition, and medical conditions. - lonizing radiation has been used in devices that destroy cancer tissue, kill organisms that spoil food, control insect populations, and power spacecraft instruments.

### 24.6 THE INTERCONVERSION OF MASS AND ENERGY

Most of the nuclear processes we've considered so far have involved radioactive decay, in which a nucleus emits one or a few small particles or photons to become a more stable, slightly lighter nucleus. Two other nuclear processes cause much greater mass changes. In nuclear fission, a heavy nucleus splits into two much lighter nuclei, emitting several small particles at the same time. In nuclear fusion, the opposite process occurs: two lighter nuclei combine to form a heavier one. Both fission and fusion release enormous quantities of energy. Let's take a look at the origins of this energy by first examining the change in mass that accompanies the breakup of a nucleus into its nucleons and then considering the energy that is equivalent to this mass change.

## The Mass Difference Between a Nucleus and Its Nucleons

For almost a century, we have known that mass and energy are interconvertible. Thus, the separate mass and energy conservation laws are combined to state that the total quantity of mass-energy in the universe is constant. Therefore, when any reacting system releases or absorbs energy, it also loses or gains mass.

This relation between mass and energy is not important for chemical reactions because the energy changes involved in breaking or forming chemical bonds are so small that the mass changes are negligible. For example, when 1 mol of water breaks up into its atoms, heat is absorbed and we have:

$$
\mathrm{H}_{2} \mathrm{O}(g) \longrightarrow 2 \mathrm{H}(g)+\mathrm{O}(g) \quad \Delta H_{\mathrm{rxn}}^{\circ}=2 \times \mathrm{BE} \text { of } \mathrm{O}-\mathrm{H}=934 \mathrm{~kJ}
$$

We find the mass that is equivalent to this energy from Einstein's equation:

$$
\begin{equation*}
E=m c^{2} \quad \text { or } \quad \Delta E=\Delta m c^{2} \quad \text { so } \quad \Delta m=\frac{\Delta E}{c^{2}} \tag{24.8}
\end{equation*}
$$

where $\Delta m$ is the mass difference between reactants and products:

$$
\Delta m=m_{\text {products }}-m_{\text {reactants }}
$$

Substituting the heat of reaction (in $\mathrm{J} / \mathrm{mol}$ ) for $\Delta E$ and the numerical value for $c$ $\left(2.9979 \times 10^{8} \mathrm{~m} / \mathrm{s}\right)$, we obtain

$$
\Delta m=\frac{9.34 \times 10^{5} \mathrm{~J} / \mathrm{mol}}{\left(2.9979 \times 10^{8} \mathrm{~m} / \mathrm{s}\right)^{2}}=1.04 \times 10^{-11} \mathrm{~kg} / \mathrm{mol}=1.04 \times 10^{-8} \mathrm{~g} / \mathrm{mol}
$$

(Units of $\mathrm{kg} / \mathrm{mol}$ are obtained because the joule includes the kilogram: $1 \mathrm{~J}=$ $1 \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}^{2}$.) The mass of 1 mol of $\mathrm{H}_{2} \mathrm{O}$ molecules (reactant) is about 10 ng less than the combined masses of 2 mol of H atoms and 1 mol of O atoms (products), a change difficult to measure with even the most sophisticated balance. Such minute mass changes when bonds break or form allow us to assume that, for all practical purposes, mass is conserved in chemical reactions.

The much larger mass change that accompanies a nuclear process is related to the enormous energy required to bind the nucleus together from its parts. In an analogy with the calculation above involving the water molecule, consider the change in mass that occurs when one ${ }^{12} \mathrm{C}$ nucleus breaks apart into its nucleonssix protons and six neutrons: Apago PDF Fnhancer

$$
{ }^{12} \mathrm{C} \longrightarrow 6{ }_{1}^{1} \mathrm{p}+6{ }_{0}^{1} \mathrm{n}
$$

We calculate this mass difference in a special way. By combining the mass of six H atoms and six neutrons and then subtracting the mass of one ${ }^{12} \mathrm{C}$ atom, the masses of the electrons cancel: six $\mathrm{e}^{-}$(in six ${ }^{1} \mathrm{H}$ atoms) cancel six $\mathrm{e}^{-}$(in one ${ }^{12} \mathrm{C}$ atom). The mass of one ${ }^{1} \mathrm{H}$ atom is 1.007825 amu , and the mass of one neutron is 1.008665 amu , so

$$
\begin{aligned}
\text { Mass of six }{ }^{1} \mathrm{H} \text { atoms } & =6 \times 1.007825 \mathrm{amu}=6.046950 \mathrm{amu} \\
\text { Mass of six neutrons } & =6 \times 1.008665 \mathrm{amu}=6.051990 \mathrm{amu} \\
\hline \text { Total mass } & =12.098940 \mathrm{amu}
\end{aligned}
$$

The mass of the reactant, one ${ }^{12} \mathrm{C}$ atom, is 12 amu (exactly). The mass difference $(\Delta m)$ we obtain is the total mass of the nucleons minus the mass of the nucleus:

$$
\begin{aligned}
\Delta m & =12.098940 \mathrm{amu}-12.000000 \mathrm{amu} \\
& =0.098940 \mathrm{amu} /{ }^{12} \mathrm{C}=0.098940 \mathrm{~g} / \mathrm{mol}{ }^{12} \mathrm{C}
\end{aligned}
$$

First, and most important, note that the mass of the nucleus is less than the combined masses of its nucleons: there is always a mass decrease when nucleons form a nucleus. Second, note that the mass change of this nuclear process $\left(9.89 \times 10^{-2} \mathrm{~g} / \mathrm{mol}\right)$ is nearly 10 million times that of the chemical process $\left(10.4 \times 10^{-9} \mathrm{~g} / \mathrm{mol}\right)$ we saw earlier and easily observed on any laboratory balance.

## Nuclear Binding Energy and the Binding Energy per Nucleon

Once again, Einstein's equation for the relation between mass and energy allows us to find the energy equivalent of the mass change. For ${ }^{12} \mathrm{C}$, after converting grams to kilograms, we have

$$
\begin{aligned}
\Delta E & =\Delta m c^{2}=\left(9.8940 \times 10^{-5} \mathrm{~kg} / \mathrm{mol}\right)\left(2.9979 \times 10^{8} \mathrm{~m} / \mathrm{s}\right)^{2} \\
& =8.8921 \times 10^{12} \mathrm{~J} / \mathrm{mol}=8.8921 \times 10^{9} \mathrm{~kJ} / \mathrm{mol}
\end{aligned}
$$

This quantity of energy is called the nuclear binding energy for carbon-12, and the positive value means energy is absorbed. The nuclear binding energy is the energy required to break 1 mol of atoms into neutrons and hydrogen atoms, which equals the energy to break 1 mol of nuclei into individual nucleons:

$$
\text { Nucleus }+ \text { nuclear binding energy } \longrightarrow \text { nucleons }
$$

Thus, the nuclear binding energy is qualitatively analogous to the sum of bond energies of a covalent compound or the lattice energy of an ionic compound. But, quantitatively, nuclear binding energies are typically several million times greater.

We use joules to express the binding energy per mole of nuclei, but the joule is much too large a unit to express the binding energy of a single nucleus. Instead, nuclear scientists use the electron volt (eV), the energy an electron acquires when it moves through a potential difference of 1 volt:

$$
1 \mathrm{eV}=1.602 \times 10^{-19} \mathrm{~J}
$$

Binding energies are commonly expressed in millions of electron volts, that is, in mega-electron volts $(\mathrm{MeV})$ :

$$
1 \mathrm{MeV}=10^{6} \mathrm{eV}=1.602 \times 10^{-13} \mathrm{~J}
$$

A particularly useful factor converts the atomic mass unit to its energy equivalent in electron volts:

$$
\begin{equation*}
1 \mathrm{amu}=931.5 \times 10^{6} \mathrm{eV}=931.5 \mathrm{MeV} \tag{24.9}
\end{equation*}
$$

Earlier we found the mass change when ${ }^{12} \mathrm{C}$ breaks apart into its nucleons to be 0.098940 amu . The binding energy per ${ }^{12} \mathrm{C}$ nucleus, expressed in MeV , is

$$
\frac{\text { Binding energy }}{{ }^{12} \mathrm{C} \text { nucleus }}=0.098940 \mathrm{amu} \times \frac{931.5 \mathrm{MeV}}{1 \mathrm{amu}}=92.16 \mathrm{MeV}
$$

We can compare the stability of nuclides of different elements by determining the binding energy pernueleon For ${ }^{12} \mathrm{C}$ we have

Binding energy per nucleon $=\frac{\text { binding energy }}{\text { no. of nucleons }}=\frac{92.16 \mathrm{MeV}}{12 \text { nucleons }}=7.680 \mathrm{MeV} /$ nucleon

## SAMPLE PROBLEM 24.6 Calculating the Binding Energy per Nucleon

PROBLEM Iron-56 is an extremely stable nuclide. Compute the binding energy per nucleon for ${ }^{56} \mathrm{Fe}$ and compare it with that for ${ }^{12} \mathrm{C}$ (mass of ${ }^{56} \mathrm{Fe}$ atom $=55.934939 \mathrm{amu}$; mass of ${ }^{1} \mathrm{H}$ atom $=1.007825 \mathrm{amu}$; mass of neutron $\left.=1.008665 \mathrm{amu}\right)$.
PLAN Iron-56 has 26 protons and 30 neutrons. We calculate the mass difference, $\Delta m$, when the nucleus forms by subtracting the given mass of one ${ }^{56} \mathrm{Fe}$ atom from the sum of the masses of $26{ }^{1} \mathrm{H}$ atoms and 30 neutrons. To find the binding energy per nucleon, we multiply $\Delta m$ by the equivalent in MeV ( $931.5 \mathrm{MeV} / \mathrm{amu}$ ) and divide by the number of nucleons (56).
SOLUTION Calculating the mass difference, $\Delta m$ :

$$
\begin{aligned}
\text { Mass difference } & =\left[\left(26 \times \text { mass }{ }^{1} \mathrm{H} \text { atom }\right)+(30 \times \text { mass neutron })\right]-\text { mass }{ }^{56} \mathrm{Fe} \text { atom } \\
& =[(26)(1.007825 \mathrm{amu})+(30)(1.008665 \mathrm{amu})]-55.934939 \mathrm{amu} \\
& =0.52846 \mathrm{amu}
\end{aligned}
$$

Calculating the binding energy per nucleon:
Binding energy per nucleon $=\frac{0.52846 \mathrm{amu} \times 931.5 \mathrm{MeV} / \mathrm{amu}}{56 \text { nucleons }}=8.790 \mathrm{MeV} /$ nucleon
$\mathrm{An}{ }^{56} \mathrm{Fe}$ nucleus would require more energy per nucleon to break up into its nucleons than would ${ }^{12} \mathrm{C}(7.680 \mathrm{MeV} /$ nucleon $)$, so ${ }^{56} \mathrm{Fe}$ is more stable than ${ }^{12} \mathrm{C}$.
CHECK The answer is consistent with the great stability of ${ }^{56} \mathrm{Fe}$. Given the number of decimal places in the values, rounding to check the math is useful only to find a major error. The number of nucleons (56) is an exact number, so we retain four significant figures.
FOLLOW-UP PROBLEM 24.6 Uranium-235 is an essential component of the fuel in nuclear power plants. Calculate the binding energy per nucleon for ${ }^{235} \mathrm{U}$. Is this nuclide more or less stable than ${ }^{12} \mathrm{C}$ (mass of ${ }^{235} \mathrm{U}$ atom $=235.043924 \mathrm{amu}$ )?

Fission or Fusion: Means of Increasing the Binding Energy Per Nucleon Calculations similar to those in Sample Problem 24.6 for other nuclides show that the binding energy per nucleon varies considerably. The essential point is that the greater the binding energy per nucleon, the more stable the nuclide.

Figure 24.12 shows a plot of the binding energy per nucleon vs. mass number. It provides information about nuclide stability and the two possible processes nuclides can undergo to form more stable nuclides. Most nuclides with fewer than 10 nucleons have a relatively small binding energy per nucleon. The ${ }^{4} \mathrm{He}$ nucleus is an exception-it is stable enough to be emitted intact as an $\alpha_{2}$ particle. Above

The most important observation is that the binding energy per nucleon peaks at elements with $A \approx 60$. In other words, nuclides become more stable with increasing mass number up to around 60 nucleons and then become less stable with higher numbers of nucleons. The existence of a peak of stability suggests that there are two ways nuclides can increase their binding energy per nucleon:

- Fission. A heavier nucleus can split into lighter ones (closer to $A \approx 60$ ) by undergoing fission. The product nuclei have greater binding energy per nucleon (are more stable) than the reactant nucleus, and the difference in energy is released. Nuclear power plants generate energy through fission, as do atomic bombs (Section 24.7).
- Fusion. Lighter nuclei, on the other hand, can combine to form a heavier one (closer to $A \approx 60$ ) by undergoing fusion. Once again, the product is more stable than the reactants, and energy is released. The Sun and other stars generate energy through fusion, as do thermonuclear (hydrogen) bombs. In these examples and in all current research efforts for developing fusion as a useful energy source, hydrogen nuclei fuse to form the very stable helium-4 nucleus.

In Section 24.7, we examine fission and fusion and the industrial energy facilities designed to utilize them.

## Section Summary

The mass of a nucleus is less than the sum of the masses of its nucleons. The energy equivalent to this mass difference is the nuclear binding energy, often expressed in units of MeV . - The binding energy per nucleon is a measure of nuclide stability and varies with the number of nucleons. Nuclides with $A \approx 60$ are most stable. - Lighter nuclides join (fusion) or heavier nuclides split (fission) to create more stable products.

Figure 24.12 The variation in binding energy per nucleon. A plot of the binding energy per nucleon vs. mass number shows that nuclear stability is greatest in the region near ${ }^{56} \mathrm{Fe}$. Lighter nuclei may undergo fusion to become more stable; heavier ones may undergo fission. Note the exceptional stability of ${ }^{4} \mathrm{He}$ among extremely light nuclei.

Lise Meitner (1878-1968) Until very recently, this extraordinary physicist received little of the acclaim she deserved. Meitner worked in the laboratory of the chemist Otto Hahn, and she was responsible for the discovery of protactinium (Pa; $Z=91)$ and numerous radioisotopes. After leaving Germany in advance of the Nazi domination, Meitner proposed the correct explanation of nuclear fission. In 1944 Hahn received the Nobel Prize in chemistry, but he did not even acknowledge Meitner in his acceptance speech. Today, most physicists believe Meitner should have received the prize. Despite controversy over names for elements 104 to 109 , it was widely agreed that element 109 should be named meitnerium.

### 24.7 APPLICATIONS OF FISSION AND FUSION

Of the many beneficial applications of nuclear reactions, the greatest is the potential for almost limitless amounts of energy, which is based on the multimillionfold increase in energy yield of nuclear reactions over chemical reactions. Our experience with nuclear energy from power plants in the late $20^{\text {th }}$ century, however, has shown that we must improve ways to tap this energy source safely and economically and deal with the waste generated. In this section, we discuss how fission and fusion occur and how we are applying them.

## The Process of Nuclear Fission

During the mid-1930s, Enrico Fermi and coworkers bombarded uranium $(Z=92)$ with neutrons in an attempt to synthesize transuranium elements. Many of the unstable nuclides produced were tentatively identified as having $Z>92$, but other scientists were skeptical. Four years later, the German chemist Otto Hahn and his associate F. Strassmann showed that one of these unstable nuclides was an isotope of barium $(Z=56)$. The Austrian physicist Lise Meitner, a coworker of Hahn, and her nephew Otto Frisch proposed that barium resulted from the splitting of the uranium nucleus into smaller nuclei, a process that they called fission as an analogy to cell division in biology.

The ${ }^{235} \mathrm{U}$ nucleus can split in many different ways, giving rise to various daughter nuclei, but all routes have the same general features. Figure 24.13 depicts one of these fission patterns. Neutron bombardment results in a highly excited ${ }^{236} \mathrm{U}$ nucleus, which splits apart in $10^{-14} \mathrm{~s}$. The products are two nuclei of unequal mass, two or three neutrons (average of 2.4), and a large quantity of energy. A single ${ }^{235} \mathrm{U}$ nucleus releases $3.5 \times 10^{-11} \mathrm{~J}$ when it splits; 1 mol of ${ }^{235} \mathrm{U}$ (about $\frac{1}{2}$ blaceases $2.1 \mathbb{1} 1^{43} \mathrm{~J}$-Far billiontimesasmuch energy as burning $\frac{1}{2} \mathrm{lb}$ of coal (about $2 \times 10^{4} \mathrm{~J}$ )!

We harness the energy of nuclear fission, much of which eventually appears as heat, by means of a chain reaction, illustrated in Figure 24.14: the two to three neutrons that are released by the fission of one nucleus collide with other fissionable nuclei and cause them to split, releasing more neutrons, which then col-

Figure 24.13 Induced fission of ${ }^{235} \mathrm{U}$. A neutron bombarding a ${ }^{235} \mathrm{U}$ nucleus results in an extremely unstable ${ }^{236} U$ nucleus, which becomes distorted in the act of splitting. In this case, which shows one of many possible splitting patterns, the products are ${ }^{92} \mathrm{Kr}$ and ${ }^{141} \mathrm{Ba}$. Three neutrons and a great deal of energy are released also.

 the first fission event collide with other nuclei, causing their fission and the production of more neutrons to continue the process. Note that various product nuclei form. The vertical dashed lines identify succeeding "generations" of neutrons.
lide with other nuclei, and so on, in a self-sustaining process. In this manner, the energy released increases rapidly because each fission event in a chain reaction releases two to three times as much energy as the preceding one.

Whether a chain reaction occurs depends on the mass (and thus the volume) of the fissionable sample. If the piece of uranium is large enough, the product neutrons strike another fissionable nucleus before flying out of the sample, and a chain reaction takes place. The mass required to achieve a chain reaction is called the critical mass. If the sample has less than the critical mass (a subcritical mass), too many product neutrons leave the sample before they collide with and cause the fission of another ${ }^{235} \mathrm{U}$ nucleus, and thus a chain reaction does not occur.
Uncontrolled Fission: The Atomic Bomb An uncontrolled chain reaction can be adapted to make an extremely powerful explosive, as several of the world's leading atomic physicists suspected just prior to the beginning of World War II. In August 1939, Albert Einstein wrote the president of the United States, Franklin Delano Roosevelt, to this effect, warning of the danger of allowing the Nazi government to develop this power first. It was this concern that led to the Manhat$\tan$ Project, an enormous scientific effort to develop a bomb based on nuclear fission, which was initiated in 1941.* In August 1945, the United States detonated two atomic bombs over Japan, and the horrible destructive power of these bombs was a major factor in the surrender of the Japanese a few days later.

[^39]

Figure 24.15 An atomic bomb based on ${ }^{235} \mathrm{U}$. Small TNT explosions bring subcritical masses together, and the chain reaction occurs.

Figure 24.16 A light-water nuclear reactor. A, Photo of a facility showing the concrete containment shell and nearby water source. B, Schematic of a lightwater reactor.

In an atomic bomb, small explosions of trinitrotoluene (TNT) bring subcritical masses of fissionable material together to exceed the critical mass, and the ensuing chain reaction brings about the explosion (Figure 24.15). The proliferation of nuclear power plants, which use fissionable materials to generate energy for electricity, has increased concern that more countries (and unscrupulous individuals) may have access to such material for making bombs. Since the devastating terrorist attacks of September 11, 2001 in the United States, this concern has been heightened.
Controlled Fission: Nuclear Energy Reactors Like a coal-fired power plant, $a$ nuclear power plant generates heat to produce steam, which turns a turbine attached to an electric generator. But a nuclear plant has the potential to produce electric power much more cleanly than can the combustion of coal.

Heat generation takes place in the reactor core of a nuclear plant (Figure 24.16). The core contains the fuel rods, which consist of fuel enclosed in tubes of a corrosion-resistant zirconium alloy. The fuel is uranium(IV) oxide $\left(\mathrm{UO}_{2}\right)$ that has been enriched from $0.7 \%{ }^{235} \mathrm{U}$, the natural abundance of this fissionable isotope, to the $3 \%$ to $4 \%{ }^{235} \mathrm{U}$ required to sustain a chain reaction in a practical vol-

ume. (Enrichment of nuclear fuel is the most important application of Graham's law; see the margin note, p. 215.) Sandwiched between the fuel rods are movable control rods made of cadmium or boron (or, in nuclear submarines, hafnium), substances that absorb neutrons very efficiently. When the control rods are moved between the fuel rods, the chain reaction slows because fewer neutrons are available to bombard uranium atoms; when they are removed, the chain reaction speeds up. Neutrons that leave the fuel-rod assembly collide with a reflector, usually made of a beryllium alloy, which absorbs very few neutrons. Reflecting the neutrons back to the fuel rods speeds the chain reaction.

Flowing around the fuel and control rods in the reactor core is the moderator, a substance that slows the neutrons, making them much better at causing fission than the fast ones emerging directly from the fission event. In most modern reactors, the moderator also acts as the coolant, the fluid that transfers the released heat to the steam-producing region. Light-water reactors use $\mathrm{H}_{2} \mathrm{O}$ as the moderator because ${ }^{1} \mathrm{H}$ absorbs neutrons to some extent; in heavy-water reactors, $\mathrm{D}_{2} \mathrm{O}$ is used. The advantage of $\mathrm{D}_{2} \mathrm{O}$ is that it absorbs very few neutrons, leaving more available for fission, so heavy-water reactors can use uranium that has been less enriched. As the coolant flows around the encased fuel, pumps circulate it through coils that transfer its heat to the water reservoir. Steam formed in the reservoir turns the turbine that runs the generator. The steam is then condensed in large cooling towers (see Figure 13.22 , p. 521) using water from a lake or river and returned to the water reservoir.

Some major accidents at nuclear plants have caused decidedly negative public reactions. In 1979, malfunctions of coolant pumps and valves at the ThreeMile Island facility in Pennsylvania led to melting of some of the fuel and damage to the reactor core, but the release of only a very small amount (about 1 Ci ) of radioactive gases into the atmosphere. In 1986, a million times as much radioactivity ( 1 MCi ) was released when acomigsystem faite athe chermbyplant in Ukraine caused a much greater melting of fuel and an uncontrolled reaction. High-pressure steam and ignited graphite moderator rods caused the reactor building to explode and expel radioactive debris. Carried by prevailing winds, the radioactive particles contaminated vegetables and milk in much of Europe. And, as we said earlier, health officials have evidence that thousands of people living near the accident have already developed or may eventually develop cancer from radiation exposure. The design of the Chernobyl plant was particularly unsafe because, unlike reactors in the United States and western Europe, the reactor was not contained in a massive, concrete building.*

Despite potential safety problems, nuclear power remains an important source of electricity. In the late 1990s, nearly every European country employed nuclear power, and it is the major power source in some countries-Sweden creates $50 \%$ of its electricity this way and France almost $80 \%$. Currently, the United States obtains about $20 \%$ of its electricity from nuclear power, and Canada slightly less. As our need for energy grows and climate change from fossil-fuel consumption continues, safer reactors are being designed and are likely to be built.

However, even a smoothly operating plant has certain inherent problems. The problem of thermal pollution is common to all power plants. Water used to condense the steam is several degrees warmer when returned to its source, which can harm aquatic organisms (Section 13.4). A more serious problem is nuclear waste disposal. Many of the fission products formed in nuclear reactors have long halflives, and no satisfactory plan for their permanent disposal has yet been devised. Proposals to place the waste in containers and bury them in deep bedrock cannot

[^40]"Breeding" Nuclear Fuel Uranium235 is not an abundant isotope. One solution to a potential fuel shortage is a breeder reactor, designed to consume one type of nuclear fuel as it produces another. Outside the moderator, fuel rods are surrounded by natural $\mathrm{U}_{3} \mathrm{O}_{8}$, which contains $99.3 \%$ nonfissionable ${ }^{238} \mathrm{U}$ atoms. As neutrons formed during ${ }^{235} \mathrm{U}$ fission escape the fuel rod, they collide with ${ }^{238} \mathrm{U}$, transmuting it into ${ }^{239} \mathrm{Pu}$, another fissionable nucleus:
\[

$$
\begin{gathered}
{ }_{92}^{238} \mathrm{U}+{ }_{0}^{1} \mathrm{n} \mathrm{H} \longrightarrow{ }_{9}^{239} \mathrm{U} \\
\left(t_{1 / 2} \text { of }{ }_{92}^{239} \mathrm{U}=23.5 \mathrm{~min}\right) \\
{ }_{92}^{239} \mathrm{U} \longrightarrow{ }_{9}^{239} \mathrm{~Np}+{ }_{-1}^{0} \beta \\
\left(t_{1 / 2} \text { of }{ }_{93}^{239} \mathrm{~Np}=2.35 \text { days }\right) \\
{ }_{93}^{239} \mathrm{~Np} \longrightarrow{ }_{9}^{239}{ }_{24}^{239} \mathrm{Pu}+{ }_{-1}^{0} \beta \\
\left(t_{1 / 2} \text { of }{ }_{94}^{239} \mathrm{Pu}=2.4 \times 10^{4} \mathrm{yr}\right)
\end{gathered}
$$
\]

Although breeder reactors can make fuel as they operate, they are difficult and expensive to build, and ${ }^{239} \mathrm{Pu}$ is extremely toxic and long lived. Breeder reactors are not used in the United States, although several are operating in Europe and Japan.

Figure 24.17 The tokamak design for magnetic containment of a fusion plasma. The donut-shaped chamber of the tokamak (photo, top; schematic, bottom) contains the plasma within a helical magnetic field.
possibly be field-tested for the thousands of years the material will remain harmful. Leakage of radioactive material into groundwater is a danger, and earthquakes can occur even in geologically stable regions. Despite studies indicating that the proposed disposal site at Yucca Mountain, Nevada, is too geologically active, the U.S. government recently approved the site. It remains to be seen whether we can operate fission reactors and dispose of the waste safely and economically.

## The Promise of Nuclear Fusion

Nuclear fusion is the ultimate source of nearly all the energy on Earth because almost all other sources depend, directly or indirectly, on the energy produced by nuclear fusion in the Sun. But the Sun and other stars generate more than energy; in fact, all the elements larger than hydrogen were formed in fusion and decay processes within stars, as the next Chemical Connections essay describes.

Much research is being devoted to making nuclear fusion a practical, direct source of energy on Earth. To understand the advantages of fusion, let's consider one of the most discussed fusion reactions, in which deuterium and tritium react:

$$
{ }_{1}^{2} \mathrm{H}+{ }_{1}^{3} \mathrm{H} \longrightarrow{ }_{2}^{4} \mathrm{He}+{ }_{0}^{1} \mathrm{n}
$$

This reaction produces $1.7 \times 10^{9} \mathrm{~kJ} / \mathrm{mol}$, an enormous quantity of energy with no radioactive byproducts. Moreover, the reactant nuclei are relatively easy to come by. We obtain deuterium from the electrolysis of water (Section 22.4). In nature, tritium forms through the cosmic (neutron) irradiation of ${ }^{14} \mathrm{~N}$ :

$$
{ }_{7}^{14} \mathrm{~N}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{1}^{3} \mathrm{H}+{ }_{6}^{12} \mathrm{C}
$$

However, this process results in a natural abundance of only $10^{-7} \%{ }^{3} \mathrm{H}$. More practically, tritium is produced in nuclear accelerators by bombarding lithium-6 or by surrounding the fusion reactor itself with material containing lithium-6:

## Apago PDF E ${ }^{6} 4^{4} \mathrm{H}^{1} \mathrm{MC}{ }^{3} \mathrm{H}^{+}{ }_{2}^{4} \mathrm{He}$

Thus, in principle, fusion seems very promising and may represent an ideal source of power. However, some extremely difficult technical problems remain. Fusion requires enormous energy in the form of heat to give the positively charged nuclei enough kinetic energy to force themselves together. The fusion of deuterium and tritium, for example, occurs at practical rates at about $10^{8} \mathrm{~K}$, a temperature hotter than the Sun's core! How can such conditions be achieved? Two current research approaches have promise. In one, atoms are stripped of their electrons at high temperatures, which results in a gaseous plasma, a neutral mixture of positive nuclei and electrons. Because of the extreme temperatures needed for fusion, no material can contain the plasma. The most successful approach to date has been to enclose the plasma within a magnetic field. The tokamak design has a donut-shaped container in which a helical magnetic field confines the plasma and prevents it from contacting the walls (Figure 24.17). Scientists at the Princeton University Plasma Physics facility have achieved some success in generating energy from fusion this way. In another approach, the high temperature is reached by using many focused lasers to compress and heat the fusion reactants. In any event, one or more major breakthroughs are needed before fusion will be realized as a practical, everyday source of energy.

## Section Summary

In nuclear fission, neutron bombardment causes a nucleus to split into two smaller nuclei and release neutrons that split other nuclei, giving rise to a chain reaction. - A nuclear power plant controls the rate of the chain reaction to produce heat that creates steam, which is used to generate electricity. - Potential hazards, such as radiation leaks, thermal pollution, and disposal of nuclear waste, remain current concerns. - Nuclear fusion holds great promise as a source of clean abundant energy, but it requires extremely high temperatures and is not yet practical. - The elements were formed through a complex series of nuclear reactions in evolving stars.

## Origin of the Elements in the Stars

How did the universe begin? Where did matter come from? How were the elements formed? Every culture has creation myths that deal with similar questions, but only recently have astronomers, physicists, and chemists begun to offer a scientific explanation. The most accepted current model proposes that a sphere of unimaginable properties-diameter of $10^{-28} \mathrm{~cm}$, density of $10^{96} \mathrm{~g} / \mathrm{mL}$ (density of a nucleus $\approx 10^{14} \mathrm{~g} / \mathrm{mL}$ ), and temperature of $10^{32} \mathrm{~K}$-exploded in a "Big Bang," for reasons not yet known, and distributed its contents through the void of space. Cosmologists consider this moment the beginning of time.

One second later, the universe was an expanding mixture of neutrons, protons, and electrons, denser than rock and hotter than an exploding hydrogen bomb (about $10^{10} \mathrm{~K}$ ). In the next few minutes, it became a gigantic fusion reactor creating the first atomic nuclei: ${ }^{2} \mathrm{H},{ }^{3} \mathrm{He}$, and ${ }^{4} \mathrm{He}$. After 10 min , more than $25 \%$ of the mass of the universe existed as ${ }^{4} \mathrm{He}$, and only about $0.025 \%$ as ${ }^{2} \mathrm{H}$. About 100 million years later, or about 15 billion years ago, gravitational forces pulled this cosmic mixture into primitive, contracting stars.

This account of the origin of the universe is based on the observation of spectra from the Sun, other stars, nearby galaxies, and cosmic (interstellar) dust. Spectral analysis of planets and chemical analysis of Earth and Moon rocks, meteorites, and cosmic-ray particles furnish data about isotope abundance. From these, a model has been developed for stellar nucleosynthesis, the creation of the elements in stars. The overall process occurs in several stages during a star's evolution, and the entire sequence of steps occurs only in very massive stars, having 10 to 100 times the mass of the Sun. Each step involves a contraction of chotar Thationduces higher temperature and heavier nüclei. Such events are forming elements in stars today. The key stages in the process are shown in Figure B24.3 and described below:

1. Hydrogen burning produces He. The initial contraction of a star heats its core to about $10^{7} \mathrm{~K}$, at which point a fusion process called hydrogen burning begins. Through three possible reaction cycles, helium is produced from the abundant protons:

$$
4{ }_{1}^{1} \mathrm{H} \longrightarrow{ }_{2}^{4} \mathrm{He}+2{ }_{1}^{0} \beta+2 v+\text { energy }
$$

2. Helium burning produces $\mathrm{C}, \mathrm{O}, \mathrm{Ne}$, and Mg . After several billion years of hydrogen burning, about $10 \%$ of the ${ }^{1} \mathrm{H}$ is consumed, and the star contracts further. The ${ }^{4} \mathrm{He}$ forms a dense core, hot enough $\left(2 \times 10^{8} \mathrm{~K}\right)$ to fuse ${ }^{4} \mathrm{He}$. The energy released during helium burning expands the remaining ${ }^{1} \mathrm{H}$ into a vast envelope: the star becomes a red giant, more than 100 times its original diameter. Within its core, pairs of ${ }^{4} \mathrm{He}$ nuclei ( $\alpha$ particles) fuse into unstable ${ }^{8} \mathrm{Be}$ nuclei $\left(t_{1 / 2}=7 \times 10^{-17} \mathrm{~s}\right.$ ), which play the role of an activated complex in chemical reactions. $\mathrm{A}^{8} \mathrm{Be}$ nucleus collides with another ${ }^{4} \mathrm{He}$ to form ${ }^{12} \mathrm{C}$. Then, further fusion with ${ }^{4} \mathrm{He}$ creates nuclei up to ${ }^{24} \mathrm{Mg}$ :

$$
{ }^{12} \mathrm{C} \xrightarrow{\alpha}{ }^{16} \mathrm{O} \xrightarrow{\alpha}{ }^{20} \mathrm{Ne} \xrightarrow{\alpha}{ }^{24} \mathrm{Mg}
$$

3. Elements through Fe and Ni form. For another 10 million years, ${ }^{4} \mathrm{He}$ is consumed, and the heavier nuclei created form a core. This core contracts and heats, expanding the star into a supergiant. Within the hot core $\left(7 \times 10^{8} \mathrm{~K}\right)$, carbon and oxygen burning occur:

$$
\begin{aligned}
& { }^{12} \mathrm{C}+{ }^{12} \mathrm{C} \longrightarrow{ }^{23} \mathrm{Na}+{ }^{1} \mathrm{H} \\
& { }^{12} \mathrm{C}+{ }^{16} \mathrm{O} \longrightarrow{ }^{28} \mathrm{Si}+\gamma
\end{aligned}
$$

Absorption of $\alpha$ particles forms nuclei up to ${ }^{40} \mathrm{Ca}$ :

Further contraction and heating to a temperature of $3 \times 10^{9} \mathrm{~K}$ allow reactions in which nuclei release neutrons, protons, and $\alpha$ particles and then recapture them. As a result, nuclei with lower binding energies supply nucleons to create those with higher binding energies. In stars of moderate mass, less than 10 times the mass of the Sun, this process stops at iron-56 and nickel-58, the nuclei with the highest binding energies.
4. Heavier elements form. In very massive stars, the next stage is the most spectacular. With all the fuel consumed, the core collapses within a second. Many Fe and Ni nuclei break down into neutrons and protons. Protons capture electrons to form neutrons, and the entire core forms an incredibly dense neutron star. (An Earth-sized star that became a neutron star would fit in the Houston Astrodome!) As the core implodes, the outer layers explode in a supernova, which expels material throughout space. A supernova occurs an average of every few hundred years in each galaxy or once every second somewhere in the universe. Figure B24.4 shows a few recently detected supernovae. The heavier elements are formed during supernova events and are found in secondgeneration stars, those that coalesce from interstellar ${ }^{1} \mathrm{H}$ and ${ }^{4} \mathrm{He}$ and the debris of exploded first-generation stars.
FnlHeavier elements form through neutron-capture processes. In the $s$-process (stow neutron-capture process), a nucleus captures a neutron, sometime over a period of 10 to 1000 years. If the resulting nucleus is unstable, it undergoes $\beta^{-}$decay to form the next element, as in this conversion of ${ }^{68} \mathrm{Zn}$ to ${ }^{70} \mathrm{Ge}$ :

$$
{ }^{68} \mathrm{Zn} \xrightarrow{\mathrm{n}}{ }^{69} \mathrm{Zn} \xrightarrow{\beta^{-}}{ }^{69} \mathrm{Ga} \xrightarrow{\text { n }}{ }^{70} \mathrm{Ga} \xrightarrow{\beta^{-}}{ }^{70} \mathrm{Ge}
$$

The stable isotopes of most heavy elements up to ${ }^{209} \mathrm{Bi}$ form by the s-process.

Less stable isotopes and those with $A$ greater than 230 cannot form by the s-process because their half-lives are too short. These form by the $r$-process (rapid neutron-capture process) during the fury of the supernova. Many neutron captures, followed by many $\beta^{-}$decays, occur in a second, as when ${ }^{56} \mathrm{Fe}$ is converted to ${ }^{79} \mathrm{Br}$ :

$$
{ }_{26}^{56} \mathrm{Fe}+23{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{26}^{79} \mathrm{Fe} \longrightarrow{ }_{35}^{79} \mathrm{Br}+9-{ }_{-1}^{0} \beta
$$

We know from the heavy elements present in the Sun that it is at least a second-generation star presently undergoing hydrogen burning. Together with its planets, it was formed from the dust of exploded stars about $4.6 \times 10^{9}$ years ago. This means that many of the atoms on Earth, including some within you, came from exploded stars and are older than the Solar System itself!

Any theory of element formation must be consistent with the element abundances we observe (Section 22.1). Although local compositions, such as those of Earth and the Sun, differ, and mineral grains in meteorites may have abnormal isotopic compositions, large regions of the universe have, on average, similar compositions. Scientists believe element forming reaches a dynamic equilibrium, resulting in relatively constant amounts of the isotopes.

## Chemical Connections continued

## Chapter Perspective and Epilog

With this chapter, our earlier picture of the nucleus as a static point of positive mass at the atom's core has changed radically. Now we picture a dynamic body, capable of a host of changes that involve incredible quantities of energy. Our attempts to apply the behavior of this minute system to benefit society have created some of the most fascinating and challenging fields in science today.

We began our investigation of chemistry 24 chapters ago, by seeing how the chemical elements and the products we make from them influence nearly every aspect of our material existence. Now we have come full circle to learn that these elements, whose patterns of behavior we have become familiar with, yet still marvel at, are continually being born in countless infernos twinkling in the night sky.

For you, the end of this course is a beginning-a chance to apply your new abilities to visualize molecular events and solve problems in whatever field you choose. For the science of chemistry, future challenges are great: What greener energy sources can satisfy our needs while minimizing climate change? What new products can feed, clothe, and house the world's people and maintain precious resources? How can we apply our new genetic insight to defend against cancer, AIDS, and other dread diseases? What new materials and technologies can make life more productive and meaningful? The questions are many, but the science of chemistry will always be one of our most powerful means of answering them.

CHAPTER REVIEW GUIDE
The following sections provide many aids to help you study this chapter. (Numbers in parentheses refer to pages, unless noted otherwise.)
Learning Objectives These are concepts and skills you should know after studying this chapter.

Relevant section and/or sample problem (SP) numbers appear in parentheses.

## Understand These Concepts

1. How nuclear changes differ, in general, from chemical changes (Introduction)
2. The meanings of radioactivity, nucleon, nuclide, and isotope (Section 24.1)
3. Characteristics of three types of radioactive emissions: $\alpha, \beta$, and $\gamma$ (Section 24.1)
4. The various modes of radioactive decay and how each changes the values of $A$ and $Z$ (Section 24.1)
5. How the $N / Z$ ratio, the even-odd nature of $N$ and $Z$, and magic numbers correlate with nuclear stability (Section 24.1)
6. How an unstable nuclide's mass number or $N / Z$ ratio correlates with its mode of decay (Section 24.1)
7. How a decay series combines numerous decay steps and ends with a stable nuclide (Section 24.1)
8. Why radioactive decay is a first-order process; the meanings of decay rate and specific activity (Section 24.2)
9. The meaning of half-life in the context of radioactive decay (Section 24.2)
10. How the specific activity of an isotope in an object is used to determine the object's age (Section 24.2)
11. How particle accelerators and reactors are used to synthesize new nuclides (Section 24.3)
12. The units of radiation dose; the effects on living tissue of various dosage levels; the inverse relationship between the mass and charge of an emission and its penetrating power (Section 24.4)
13. How ionizing radiation creates free radicals that damage tissue; sources and risks of ionizing radiation (Section 24.4)
14. How radioisotopes are used in research, analysis, and medical diagnosis (Section 24.5)
15. Why the mass of a nucleus is less than the total mass of its nucleons and how this mass difference is related to the nuclear bind-
Finglenegg (Section 24.6)
16. How nuclear stability is related to binding energy per nucleon (Section 24.6)
17. How heavy nuclides undergo fission and lighter ones undergo fusion to increase the binding energy per nucleon (Section 24.6)
18. The current application of fission and potential application of fusion to produce energy (Section 24.7)

## Master These Skills

1. Expressing the mass and charge of a particle with the ${ }_{Z}^{A} \mathrm{X}$ notation (Section 24.1; see also Section 2.5)
2. Using changes in the values of $A$ and $Z$ to write and balance nuclear equations (SP 24.1)
3 . Using the $N / Z$ ratio, the even-odd nature of $N$ and $Z$, and the presence of magic numbers to predict nuclear stability (SP 24.2)
3. Using the atomic mass of the element or the $N / Z$ ratio to predict the mode of decay of an unstable nuclide (SP 24.3)
4. Converting units of radioactivity (Section 24.2)
5. Calculating specific activity, decay constant, half-life, and number of nuclei (Section 24.2 and SP 24.4)
6. Estimating the age of an object from the specific activity and half-life of carbon-14 (SP 24.5)
7. Writing notations and balancing equations for nuclear transmutation (Section 24.3)
8. Calculating radiation dose and converting units (Section 24.4)
9. Calculating the mass difference between a nucleus and its nucleons and the energy equivalent (Section 24.6)
10. Calculating the binding energy per nucleon and using it to compare stabilities of nuclides (SP 24.6)

Key Terms These important terms appear in boldface in the chapter and are defined again in the Glossary.

## Section 24.1

radioactivity (1066)
nucleon (1066)
nuclide (1066)
isotope (1066)
alpha ( $\alpha$ ) particle (1067)
beta $(\beta)$ particle (1067)
$\operatorname{gamma}(\gamma)$ ray (1067)
$\alpha$ decay (1069)
$\beta^{-}$decay (1069)
positron emission (1069)
positron $\left(\beta^{+}\right)(1069)$
electron ( $\mathrm{e}^{-}$) capture (EC)
(1069)
gamma emission (1070)
band of stability (1071)
strong force (1072)
decay (disintegration) series (1074)

## Section 24.2

activity (A) (1074)
Geiger-Müller counter (1075)
scintillation counter (1075)
becquerel (Bq) (1076)
curie (Ci) (1076)
decay constant (1076)
half-life ( $t_{1 / 2}$ ) (1076)
radioisotopic dating (1078)
radioisotope (1078)

## Section 24.3

nuclear transmutation (1080) deuteron (1081) particle accelerator (1081) transuranium element (1082)

## Section 24.4

ionization (1082)
ionizing radiation (1082)
gray (Gy) (1083)
rad (radiation- $a$ bsorbed $d$ ose) (1083)
rem (roentgen equivalent for man) (1083)
sievert (Sv) (1083)
free radical (1084)
background radiation (1084)

## Section 24.5

tracer (1087)

## Section 24.6

fission (1090)
fusion (1090)
nuclear binding energy (1092) electron volt (eV) (1092)

## Section 24.7

chain reaction (1094)
critical mass (1095)
reactor core (1096)
stellar nucleosynthesis (1099)

Key Equations and Relationships Numbered and screened concepts are listed for you to refer to or memorize.
24.1 Balancing a nuclear equation (1067):
$\underset{\text { Total }}{Z}{ }_{Z}^{\text {Tota }}$ Reactants $={ }_{\text {Total }}^{\text {Total }}{ }_{Z}$ Products
24.2 Defining the unit of radioactivity (curie, Ci ) (1076):
$1 \mathrm{Ci}=3.70 \times 10^{10}$ disintegrations per second ( $\mathrm{d} / \mathrm{s}$ )
24.3 Expressing the decay rate (activity) for radioactive nuclei (1076):

$$
\text { Decay rate }(\mathscr{A})=-\frac{\Delta \mathcal{N}}{\Delta t}=k \mathcal{N}
$$

24.6 Calculating the time to reach a given specific activity (age of an object in radioisotopic dating) (1079):

$$
t=\frac{1}{k} \ln \frac{\mathscr{A}_{0}}{\mathscr{A}_{t}}
$$

24.7 Writing a transmutation in shorthand notation (1080): reactant nucleus (particle in, particle(s) out) product nucleus 24.8 Adapting Einstein's equation to calculate mass difference and or nuclear binding energy (1091):

$$
\Delta m=\frac{\Delta E}{c^{2}} \quad \text { or } \quad \Delta E=\Delta m c^{2}
$$

24.9 Relating the atomic mass unit to its energy equivalent in MeV (1092):

$$
1 \mathrm{amu}=931.5 \times 10^{6} \mathrm{eV}=931.5 \mathrm{MeV}
$$

Highlighted Figures and Tables These figures ( F ) and tables ( T ) provide a visual review of key ideas.

T24.1 Chemical vs. nuclear reactions (1065)
F24.1 Radioactive emissions in an electric field (1067)
T24.2 Modes of radioactive decay (1068)

F24.2 $N$ vs. $Z$ for the stable nuclides (1071)
F24.4 Decrease in number of ${ }^{14} \mathrm{C}$ nuclei over time (1076)
F24.12 The variation in binding energy per nucleon (1093)

## Brief Solutions to FOLLOW-UP PROBLEMS Compare your solutions to these calculation steps and answers.

## $24.1{ }_{54}^{133} \mathrm{Xe} \longrightarrow{ }_{55}^{133} \mathrm{Cs}+{ }_{-1}^{0} \beta$

$24.2{ }^{31} \mathrm{P}$ has an even $N(16)$, but ${ }^{30} \mathrm{P}$ has both $N$ and $Z$ odd. ${ }^{31} \mathrm{P}$ also has a slightly higher $N / Z$ ratio that is closer to the band of stability. 24.3 (a) $Z=26$ is iron (Fe), and the atomic mass is 55.85 . The $A$ value of 61 is higher: $\beta^{-}$decay; (b) $Z>83$, which is too high for stability: $\alpha$ decay

$$
24.4 \ln \mathscr{A}_{t}=-k t+\ln \mathscr{A}_{0}
$$

$$
\begin{aligned}
& =-\left(\frac{\ln 2}{15 \mathrm{~h}} \times 4.0 \text { days } \times \frac{24 \mathrm{~h}}{1 \text { day }}\right)+\ln \left(2.5 \times 10^{9}\right) \\
& =17.20 \\
\mathscr{A}_{t} & =3.0 \times 10^{7} \mathrm{~d} / \mathrm{s}
\end{aligned}
$$

$24.5 t=\frac{1}{k} \ln \frac{\mathscr{A}_{0}}{\mathscr{A}_{t}}=\frac{5730 \mathrm{yr}}{\ln 2} \ln \left(\frac{15.3 \mathrm{~d} / \mathrm{min} \cdot \mathrm{g}}{9.41 \mathrm{~d} / \mathrm{min} \cdot \mathrm{g}}\right)=4.02 \times 10^{3} \mathrm{yr}$ The mummy case is about 4000 years old.
$24.6{ }^{235} \mathrm{U}$ has $92{ }_{1}^{1} \mathrm{p}$ and $143{ }_{0}^{1} \mathrm{n}$.
$\Delta m=[(92 \times 1.007825 \mathrm{amu})+(143 \times 1.008665 \mathrm{amu})]$

$$
-235.043924 \mathrm{amu}=1.9151 \mathrm{amu}
$$

$\frac{\text { Binding energy }}{\text { nucleon }}=\frac{1.9151 \mathrm{amu} \times \frac{931.5 \mathrm{MeV}}{1 \mathrm{amu}}}{235 \text { nucleons }}$

$$
=7.591 \mathrm{MeV} / \text { nucleon }
$$

Therefore, ${ }^{235} \mathrm{U}$ is less stable than ${ }^{12} \mathrm{C}$.

## PROBLEMS

Problems with colored numbers are answered in Appendix E and worked in detail in the Student Solutions Manual. Problem sections match those in the text and provide the numbers of relevant sample problems. Most offer Concept Review Questions, Skill-Building Exercises (grouped in pairs covering the same concept), and Problems in Context. The Comprehensive Problems are based on material from any section or previous chapter.

## Radioactive Decay and Nuclear Stability

(Sample Problems 24.1 to 24.3)

## - Concept Review Questions

24.1 How do chemical and nuclear reactions differ in
(a) Magnitude of the energy change?
(b) Effect on rate of increasing temperature?
(c) Effect on rate of higher reactant concentration?
(d) Effect on yield of higher reactant concentration?
24.2 Sulfur has four naturally occurring stable isotopes. The one with the lowest mass number is sulfur-32, which is also the most abundant (95.02\%).
(a) What percentage of the S atoms in a matchhead are ${ }^{32} \mathrm{~S}$ ?
(b) The isotopic mass of ${ }^{32} \mathrm{~S}$ is 31.972070 amu . Is the atomic mass of $S$ larger, smaller, or equal to this mass? Explain.
24.3 What led Marie Curie to draw the following conclusions?
(a) Radioactivity is a property of the element and not the compound in which it is found. (b) A highly radioactive element, aside from uranium, occurs in pitchbleutde OOO PDE
24.4 Which of the following produce an atom of a different element: (a) $\alpha$ decay; (b) $\beta^{-}$decay; (c) $\gamma$ emission; (d) $\beta^{+}$emission; (e) $\mathrm{e}^{-}$capture? Show how $Z$ and $N$ change, if at all, with each process.
24.5 Why is ${ }_{2}^{3} \mathrm{He}$ stable, but ${ }_{2}^{2} \mathrm{He}$ has never been detected?
24.6 How do the modes of decay differ for a neutron-rich nuclide and a proton-rich nuclide?
24.7 Why might it be difficult to use only a nuclide's $N / Z$ ratio to predict whether it will decay by $\beta^{+}$emission or by $\mathrm{e}^{-}$capture? What other factor is important?

## - Skill-Building Exercises (grouped in similar pairs)

24.8 Write balanced nuclear equations for the following:
(a) Alpha decay of ${ }_{92}^{234} \mathrm{U}$
(b) Electron capture by neptunium-232
(c) Positron emission by ${ }_{7}^{12} \mathrm{~N}$
24.9 Write balanced nuclear equations for the following:
(a) $\beta^{-}$decay of sodium -26
(b) $\beta^{-}$decay of francium- 223
(c) Alpha decay of ${ }_{83}^{212} \mathrm{Bi}$
24.10 Write balanced nuclear equations for the following:
(a) $\beta^{-}$emission by magnesium -27
(b) $\beta^{+}$emission by ${ }_{12}^{23} \mathrm{Mg}$
(c) Electron capture by ${ }_{46}^{103} \mathrm{Pd}$
24.11 Write balanced nuclear equations for the following:
(a) $\beta^{-}$decay of silicon- 32
(b) Alpha decay of polonium-218
(c) Electron capture by ${ }_{49}^{110} \mathrm{In}$
24.12 Write balanced nuclear equations for the following:
(a) Formation of ${ }_{22}^{48} \mathrm{Ti}$ through positron emission
(b) Formation of silver-107 through electron capture
(c) Formation of polonium-206 through $\alpha$ decay
24.13 Write balanced nuclear equations for the following:
(a) Formation of ${ }_{95}^{241} \mathrm{Am}$ through $\beta^{-}$decay
(b) Formation of ${ }_{89}^{228} \mathrm{Ac}$ through $\beta^{-}$decay
(c) Formation of ${ }_{83}^{203} \mathrm{Bi}$ through $\alpha$ decay
24.14 Write balanced nuclear equations for the following:
(a) Formation of ${ }^{186}$ Ir through electron capture
(b) Formation of francium-221 through $\alpha$ decay
(c) Formation of iodine-129 through $\beta^{-}$decay
24.15 Write balanced nuclear equations for the following:
(a) Formation of ${ }^{52} \mathrm{Mn}$ through positron emission
(b) Formation of polonium-215 through $\alpha$ decay
(c) Formation of ${ }^{81} \mathrm{Kr}$ through electron capture
24.16 Which nuclide(s) would you predict to be stable? Why?
(a) ${ }_{8}^{20} \mathrm{O}$
(b) ${ }_{27}^{9} \mathrm{Co}$
(c) ${ }_{3}^{9} \mathrm{Li}$
24.17 Which nuclide(s) would you predict to be stable? Why?
(a) ${ }_{60}^{146} \mathrm{Nd}$
(b) ${ }_{48}^{114} \mathrm{Cd}$
(c) ${ }_{42}^{88} \mathrm{Mo}$
24.18 Which nuclide(s) would you predict to be stable? Why?
(a) ${ }^{127}$ I
(b) tin-106
(c) ${ }^{68} \mathrm{As}$
24.19 Which nuclide(s) would you predict to be stable? Why?
(a) ${ }^{48} \mathrm{~K}$
(b) ${ }^{79} \mathrm{Br}$
(c) argon-32
24.20 What is the most likely mode of decay for each?
(a) ${ }_{92}^{238} \mathrm{U}$
(b) ${ }_{24}^{48} \mathrm{Cr}$
(c) ${ }_{25}^{50} \mathrm{Mn}$
24.21 What is the most likely mode of decay for each?

(c) ${ }_{44}^{110} \mathrm{Ru}$
24.22 What is the most likely mode of decay for each?
(a) ${ }^{15} \mathrm{C}$
(b) ${ }^{120} \mathrm{Xe}$
(c) ${ }^{224} \mathrm{Th}$
24.23 What is the most likely mode of decay for each?
(a) ${ }^{106}$ In
(b) ${ }^{141} \mathrm{Eu}$
(c) ${ }^{241} \mathrm{Am}$
24.24 Why is ${ }_{24}^{52} \mathrm{Cr}$ the most stable isotope of chromium?
24.25 Why is ${ }_{20}^{40} \mathrm{Ca}$ the most stable isotope of calcium?

## Problems in Context

$24.26{ }^{237} \mathrm{~Np}$ is the parent nuclide of a decay series that starts with $\alpha$ emission, followed by $\beta^{-}$emission, and then two more $\alpha$ emissions. Write a balanced nuclear equation for each step.
24.27 Why is helium found in deposits of uranium and thorium ores? What kind of radioactive emission produces it?
24.28 In a natural decay series, how many $\alpha$ and $\beta^{-}$emissions per atom of uranium- 235 result in an atom of lead-207?

## The Kinetics of Radioactive Decay

(Sample Problems 24.4 and 24.5)

## - Concept Review Questions

24.29 What electronic process is the basis for detecting radioactivity in (a) a scintillation counter; (b) a Geiger-Müller counter?
24.30 What is the reaction order of radioactive decay? Explain.
24.31 After 1 minute, three radioactive nuclei remain from an original sample of six. Is it valid to conclude that $t_{1 / 2}$ equals 1 minute? Is this conclusion valid if the original sample contained $6 \times 10^{12}$ nuclei and $3 \times 10^{12}$ remain after 1 minute? Explain.
24.32 Radioisotopic dating depends on the constant rate of decay and formation of various nuclides in a sample. How is the proportion of ${ }^{14} \mathrm{C}$ kept relatively constant in living organisms?

Skill-Building Exercises (grouped in similar pairs)
24.33 What is the specific activity (in $\mathrm{Ci} / \mathrm{g}$ ) if 1.65 mg of an isotope emits $1.56 \times 10^{6} \alpha$ particles per second?
24.34 What is the specific activity (in $\mathrm{Ci} / \mathrm{g}$ ) if 2.6 g of an isotope emits $4.13 \times 10^{8} \beta^{-}$particles per hour?
24.35 What is the specific activity (in $\mathrm{Bq} / \mathrm{g}$ ) if $8.58 \mu \mathrm{~g}$ of an isotope emits $7.4 \times 10^{4} \alpha$ particles per minute?
24.36 What is the specific activity (in $\mathrm{Bq} / \mathrm{g}$ ) if 1.07 kg of an isotope emits $3.77 \times 10^{7} \beta^{-}$particles per minute?
24.37 If one-trillionth of the atoms of a radioactive isotope disintegrate each day, what is the decay constant of the process?
24.38 If $2.8 \times 10^{-10} \%$ of the atoms of a radioactive isotope disintegrate in 1.0 yr , what is the decay constant of the process?
24.39 If $1.00 \times 10^{-12} \mathrm{~mol}$ of ${ }^{135} \mathrm{Cs}$ emits $1.39 \times 10^{5} \beta^{-}$particles in 1.00 yr , what is the decay constant?
24.40 If $6.40 \times 10^{-9} \mathrm{~mol}$ of ${ }^{176} \mathrm{~W}$ emits $1.07 \times 10^{15} \beta^{+}$in 1.00 h , what is the decay constant?
24.41 The isotope ${ }_{83}^{212} \mathrm{Bi}$ has a half-life of 1.01 yr . What mass (in mg ) of a $2.00-\mathrm{mg}$ sample will remain after $3.75 \times 10^{3} \mathrm{~h}$ ?
24.42 The half-life of radium-226 is $1.60 \times 10^{3} \mathrm{yr}$. How many hours will it take for a $2.50-\mathrm{g}$ sample to decay to the point where 0.185 g of the isotope remains?
24.43 A rock contains $270 \mu \mathrm{~mol}$ of ${ }^{238} \mathrm{U}\left(t_{1 / 2}=4.5 \times 10^{9} \mathrm{yr}\right)$ and $110 \mu \mathrm{~mol}$ of ${ }^{206} \mathrm{~Pb}$. Assuming that all the ${ }^{206} \mathrm{~Pb}$ comes from decay of the ${ }^{238} \mathrm{U}$, estimate the rock's age.
24.44 A fabric remnant from a burial site has a ${ }^{14} \mathrm{C} /{ }^{12} \mathrm{C}$ ratio of 0.735 of the original value. How old is the fabric?

Apago PDE

## - Problems in Context

24.45 Due to decay of ${ }^{40} \mathrm{~K}$, cow's milk has a specific activity of about $6 \times 10^{-11} \mathrm{mCi}$ per milliliter. How many disintegrations of ${ }^{40} \mathrm{~K}$ nuclei are there per minute in an $8.0-\mathrm{oz}$ glass of milk?
24.46 Plutonium-239 $\left(t_{1 / 2}=2.41 \times 10^{4} \mathrm{yr}\right)$ represents a serious nuclear waste hazard. If seven half-lives are required to reach a tolerable level of radioactivity, how long must ${ }^{239} \mathrm{Pu}$ be stored?
24.47 A rock that contains $3.1 \times 10^{-15} \mathrm{~mol}$ of ${ }^{232} \mathrm{Th}\left(t_{1 / 2}=\right.$ $1.4 \times 10^{10} \mathrm{yr}$ ) has $9.5 \times 10^{4}$ fission tracks, each track representing the fission of one atom of ${ }^{232} \mathrm{Th}$. How old is the rock?
24.48 A volcanic eruption melts a large area of rock, and all gases are expelled. After cooling, ${ }_{18}^{40} \mathrm{Ar}$ accumulates from the ongoing decay of ${ }_{19}^{40} \mathrm{~K}$ in the rock ( $\left.t_{1 / 2}=1.25 \times 10^{9} \mathrm{yr}\right)$. When a piece of rock is analyzed, it is found to contain 1.38 mmol of ${ }^{40} \mathrm{~K}$ and 1.14 mmol of ${ }^{40} \mathrm{Ar}$. How long ago did the rock cool?

## Nuclear Transmutation: Induced Changes in Nuclei

## - Concept Review Questions

24.49 Irene and Frederic Joliot-Curie converted ${ }_{13}^{27} \mathrm{Al}$ to ${ }_{15}^{30} \mathrm{P}$ in 1933. Why was this transmutation significant?
24.50 Early workers mistakenly thought neutron beams were $\gamma$ radiation. Why? What evidence led to the correct conclusion?
24.51 Why must the electrical polarity of the tubes in a linear accelerator be reversed at very short time intervals?
24.52 Why does bombardment with protons usually require higher energies than bombardment with neutrons?

## Skill-Building Exercises (grouped in similar pairs)

24.53 Determine the missing species in these transmutations, and write a full nuclear equation from the shorthand notation:
(a) ${ }^{10} \mathrm{~B}(\alpha, n)$ _
(b) ${ }^{28} \mathrm{Si}(\mathrm{d}, \ldots){ }^{29} \mathrm{P}\left(\right.$ where d is a deuteron, $\left.{ }^{2} \mathrm{H}^{+}\right)$
(c) _ $(\alpha, 2 \mathrm{n}){ }^{244} \mathrm{Cf}$
24.54 Name the unidentified species, and write each transmutation process in shorthand notation: (a) gamma irradiation of a nuclide yields a proton, a neutron, and ${ }^{29} \mathrm{Si}$; (b) bombardment of ${ }^{252} \mathrm{Cf}$ with ${ }^{10} \mathrm{~B}$ yields five neutrons and a nuclide; (c) bombardment of ${ }^{238} \mathrm{U}$ with a particle yields three neutrons and ${ }^{239} \mathrm{Pu}$.

## - Problems in Context

24.55 Elements 104, 105, and 106 have been named rutherfordium ( Rf ), dubnium ( Db ), and seaborgium ( Sg ), respectively. These elements are synthesized from californium-249 by bombarding with carbon -12 , nitrogen -15 , and oxygen- 18 nuclei, respectively. Four neutrons are formed in each reaction as well. (a) Write balanced nuclear equations for the formation of these elements. (b) Write the equations in shorthand notation.

## The Effects of Nuclear Radiation on Matter

## - Concept Review Questions

24.56 The effects on matter of $\gamma$ rays and $\alpha$ particles differ. Explain.
24.57 What is a cation-electron pair, and how does it form?
24.58 Why is ionizing radiation more harmful to children than adults?
24.59 Why is $\cdot \mathrm{OH}$ more dangerous than $\mathrm{OH}^{-}$in an organism?

Skill-Building Exercises (grouped in similar pairs)
24.60 A 135-lb person absorbs $3.3 \times 10^{-7} \mathrm{~J}$ of energy from radioactive emissions. (a) How many rads does she receive? (b) How many grays (Gy) does she receive?
24.61 A $3.6-\mathrm{kg}$ laboratory animal receives a single dose of
 (b) How many joules did the animal absorb?
24.62 A 70.-kg person exposed to ${ }^{90} \mathrm{Sr}$ absorbs $6.0 \times 10^{5} \beta^{-}$particles, each with an energy of $8.74 \times 10^{-14}$ J. (a) How many grays does the person receive? (b) If the RBE is 1.0 , how many millirems is this? (c) What is the equivalent dose in sieverts (Sv)?
24.63 A laboratory rat weighs 265 g and absorbs $1.77 \times 10^{10} \beta^{-}$ particles, each with an energy of $2.20 \times 10^{-13} \mathrm{~J}$. (a) How many rads does the animal receive? (b) What is this dose in Gy? (c) If the RBE is 0.75 , what is the equivalent dose in Sv ?

## - Problems in Context

24.64 If $2.50 \mathrm{pCi}\left[1 \mathrm{pCi}\right.$ (picocurie) $\left.=1 \times 10^{-12} \mathrm{Ci}\right]$ of radioactivity from ${ }^{239} \mathrm{Pu}$ is emitted in a $95-\mathrm{kg}$ human for 65 h , and each disintegration has an energy of $8.25 \times 10^{-13} \mathrm{~J}$, how many grays does the person receive?
24.65 A small region of a cancer patient's brain is exposed for 24.0 min to 475 Bq of radioactivity from ${ }^{60} \mathrm{Co}$ for treatment of a tumor. If the brain mass exposed is 1.858 g and each $\beta^{-}$particle emitted has an energy of $5.05 \times 10^{-14} \mathrm{~J}$, what is the dose in rads?

## Applications of Radioisotopes

## Concept Review Questions

24.66 What two ways are radioactive tracers used in organisms?
24.67 Why is neutron activation analysis (NAA) useful to art historians and criminologists?
24.68 Positrons cannot penetrate matter more than a few atomic diameters, but positron emission of radiotracers can be monitored in medical diagnosis. Explain.
24.69 A steel part is treated to form some iron-59. Oil used to lubricate the part emits $298 \beta^{-}$particles (with the energy charac-
teristic of ${ }^{59} \mathrm{Fe}$ ) per minute per milliliter of oil. What other information would you need to calculate the rate of removal of the steel from the part during use?

## - Problem in Context

24.70 The oxidation of methanol to formaldehyde can be accomplished by reaction with chromic acid:

$$
\begin{aligned}
6 \mathrm{H}^{+}(a q)+3 \mathrm{CH}_{3} \mathrm{OH}(a q)+ & 2 \mathrm{H}_{2} \mathrm{CrO}_{4}(a q) \longrightarrow \\
& 3 \mathrm{CH}_{2} \mathrm{O}(a q)+2 \mathrm{Cr}^{3+}(a q)+8 \mathrm{H}_{2} \mathrm{O}(l)
\end{aligned}
$$

The reaction can be studied with the stable isotope tracer ${ }^{18} \mathrm{O}$ and mass spectrometry. When a small amount of $\mathrm{CH}_{3}{ }^{18} \mathrm{OH}$ is present in the alcohol reactant, $\mathrm{CH}_{2}{ }^{18} \mathrm{O}$ forms. When a small amount of $\mathrm{H}_{2} \mathrm{Cr}^{18} \mathrm{O}_{4}$ is present, $\mathrm{H}_{2}{ }^{18} \mathrm{O}$ forms. Does chromic acid or methanol supply the O atom to the aldehyde? Explain.

## The Interconversion of Mass and Energy

(Sample Problem 24.6)
Note: Data for solving problems in this section: mass of ${ }^{1} \mathrm{H}$ atom $=1.007825 \mathrm{amu}$; mass of neutron $=1.008665 \mathrm{amu}$.

## - Concept Review Questions

24.71 Many scientists at first reacted skeptically to Einstein's equation, $E=m c^{2}$. Why?
24.72 How does a change in mass arise when a nuclide forms from nucleons?
24.73 When a nucleus forms from nucleons, is energy absorbed or released? Why?
24.74 What is the binding energy per nucleon? Why is the binding energy per nucleon, rather than per nuclide, used to compare nuclide stability?

Apago PDF

## - Skill-Building Exercises (grouped in similar pairs)

$24.75 \mathrm{~A}^{3} \mathrm{H}$ nucleus decays with an energy of 0.01861 MeV . Convert this energy into (a) electron volts; (b) joules.
24.76 Arsenic- 84 decays with an energy of $1.57 \times 10^{-15} \mathrm{~kJ}$ per nucleus. Convert this energy into (a) eV ; (b) MeV .
24.77 How many joules are released when 1.5 mol of ${ }^{239} \mathrm{Pu}$ decays, if each nucleus releases 5.243 MeV ?
24.78 How many MeV are released per nucleus when $3.2 \times 10^{-3} \mathrm{~mol}$ of chromium-49 releases $8.11 \times 10^{5} \mathrm{~kJ}$ ?
24.79 Oxygen-16 is one of the most stable nuclides. The mass of a ${ }^{16} \mathrm{O}$ atom is 15.994915 amu . Calculate the binding energy (a) per nucleon in MeV ; (b) per atom in MeV ; (c) per mole in kJ .
24.80 Lead-206 is the end product of ${ }^{238} \mathrm{U}$ decay. One ${ }^{206} \mathrm{~Pb}$ atom has a mass of 205.974440 amu . Calculate the binding energy (a) per nucleon in MeV ; (b) per atom in MeV ; (c) per mole in kJ .
24.81 Cobalt-59 is the only stable isotope of this transition metal. One ${ }^{59} \mathrm{Co}$ atom has a mass of 58.933198 amu. Calculate the binding energy (a) per nucleon in MeV ; (b) per atom in MeV ; (c) per mole in kJ .
24.82 Iodine-131 is one of the most important isotopes used in the diagnosis of thyroid cancer. One atom has a mass of 130.906114 amu. Calculate the binding energy (a) per nucleon in MeV ; (b) per atom in MeV ; (c) per mole in kJ .

## - Problem in Context

24.83 The ${ }^{80} \mathrm{Br}$ nuclide decays either by $\beta^{-}$decay or by electron capture. (a) What is the product of each process? (b) Which process releases more energy? (Masses of atoms: ${ }^{80} \mathrm{Br}=79.918528 \mathrm{amu} ;{ }^{80} \mathrm{Kr}=79.916380 \mathrm{amu} ;{ }^{80} \mathrm{Se}=$
79.916520 amu ; neglect the mass of electrons involved because these are atomic, not nuclear, masses.)

## Applications of Fission and Fusion

## - Concept Review Questions

24.84 What is the minimum number of neutrons from each fission event that must be absorbed by other nuclei for a chain reaction to be sustained?
24.85 In what main way is fission different from radioactive decay? Are all fission events in a chain reaction identical? Explain.
24.86 What is the purpose of enrichment in the preparation of fuel rods? How is it accomplished?
24.87 Describe the nature and purpose of these components of a nuclear reactor: (a) control rods; (b) moderator; (c) reflector.
24.88 State an advantage and a disadvantage of heavy-water reactors compared to light-water reactors.
24.89 What are the expected advantages of fusion reactors over fission reactors?
24.90 Why is iron the most abundant element in Earth's core?
24.91 Compare the $s$ - and $r$-processes in stellar nucleosynthesis.
24.92 What is the cosmic importance of unstable ${ }^{8} \mathrm{Be}$ ?

## Problem in Context

24.93 The reaction that will probably power the first commercial fusion reactor is

$$
{ }_{1}^{3} \mathrm{H}+{ }_{1}^{2} \mathrm{H} \longrightarrow{ }_{2}^{4} \mathrm{He}+{ }_{0}^{1} \mathrm{n}
$$ How much energy would be produced per mole of reaction? (Masses of atoms: ${ }_{1}^{3} \mathrm{H}=3.01605 \mathrm{amu} ;{ }_{1}^{2} \mathrm{H}=2.0140 \mathrm{amu}$; ${ }_{2}^{4} \mathrm{He}=4.00260 \mathrm{amu}$; mass of ${ }_{0}^{1} \mathrm{n}=1.008665 \mathrm{amu}$.)

## ECompretransiee Problems

24.94 Some ${ }_{95}^{243} \mathrm{Am}$ was present when Earth formed, but it all decayed in the next billion years. The first three steps in this decay series are emission of an $\alpha$ particle, a $\beta^{-}$particle, and another $\alpha$ particle. What other isotopes were present on the young Earth in a rock that contained some ${ }_{95}^{243} \mathrm{Am}$ ?
24.95 Curium-243 undergoes $\alpha$ decay to plutonium-239:

$$
{ }^{243} \mathrm{Cm} \longrightarrow{ }^{239} \mathrm{Pu}+\alpha
$$

(a) Find the change in mass, $\Delta m$ (in kg). (Masses: ${ }^{243} \mathrm{Cm}=$ $243.0614 \mathrm{amu} ;{ }^{239} \mathrm{Pu}=239.0522 \mathrm{amu} ;{ }^{4} \mathrm{He}=4.0026 \mathrm{amu}$; $1 \mathrm{amu}=1.661 \times 10^{-24} \mathrm{~g}$.) (b) Find the energy released in joules. (c) Find the energy released in $\mathrm{kJ} / \mathrm{mol}$ of reaction, and comment on the difference between this value and a typical heat of reaction for a chemical change, which is a few hundred $\mathrm{kJ} / \mathrm{mol}$.
24.96 Plutonium "triggers" for nuclear weapons were manufactured at the Rocky Flats plant in Colorado. An $85-\mathrm{kg}$ worker inhaled a dust particle containing $1.00 \mu \mathrm{~g}$ of ${ }_{94}^{239} \mathrm{Pu}$, which resided in his body for $16 \mathrm{~h}\left(t_{1 / 2}\right.$ of ${ }^{239} \mathrm{Pu}=2.41 \times 10^{4} \mathrm{yr}$; each disintegration released 5.15 MeV ). (a) How many rads did he receive? (b) How many grays?
24.97 Archeologists removed some charcoal from a Native American campfire, burned it in $\mathrm{O}_{2}$, and bubbled the $\mathrm{CO}_{2}$ formed into $\mathrm{Ca}(\mathrm{OH})_{2}$ solution (limewater). The $\mathrm{CaCO}_{3}$ that precipitated was filtered and dried. If 4.58 g of the $\mathrm{CaCO}_{3}$ had a radioactivity of $3.2 \mathrm{~d} / \mathrm{min}$, how long ago was the campfire?
24.98 A $5.4-\mu \mathrm{g}$ sample of ${ }^{226} \mathrm{RaCl}_{2}$ has a radioactivity of $1.5 \times 10^{5} \mathrm{~Bq}$. Calculate $t_{1 / 2}$ of ${ }^{226} \mathrm{Ra}$.
24.99 How many rads does a $65-\mathrm{kg}$ human receive each year from the approximately $10^{-8} \mathrm{~g}$ of ${ }_{6}^{14} \mathrm{C}$ naturally present in her body $\left(t_{1 / 2}=5730 \mathrm{yr}\right.$, each disintegration releases 0.156 MeV$)$ ?
24.100 The overall reaction taking place during hydrogen burning in a young star is

$$
4{ }_{1}^{1} \mathrm{H} \longrightarrow{ }_{2}^{4} \mathrm{He}+2{ }_{1}^{0} \beta+2 v+\text { energy }
$$

How much energy (in MeV ) is released per He nucleus formed? Per mole of He ? (Masses: ${ }_{1}^{1} \mathrm{H}$ atom $=1.007825 \mathrm{amu}$; ${ }_{2}^{4} \mathrm{He}$ atom $=4.00260 \mathrm{amu}$; positron $=5.48580 \times 10^{-4} \mathrm{amu}$.)
24.101 A sample of AgCl emits $175 \mathrm{nCi} / \mathrm{g}$. A saturated solution prepared from the solid emits $1.25 \times 10^{-2} \mathrm{~Bq} / \mathrm{mL}$ due to radioactive $\mathrm{Ag}^{+}$ions. What is the molar solubility of AgCl ?
24.102 The scene below depicts a neutron bombarding ${ }^{235} \mathrm{U}$ :

(a) Is this an example of fission or of fusion? (b) Identify the other nuclide formed. (c) What is the most likely mode of decay of the nuclide with $Z=55$ ?
24.103 What fraction of the ${ }^{235} \mathrm{U}\left(t_{1 / 2}=7.0 \times 10^{8} \mathrm{yr}\right)$ created when Earth was formed would remain after $2.8 \times 10^{9} \mathrm{yr}$ ?
$24.104{ }^{238} \mathrm{U}\left(t_{1 / 2}=4.5 \times 10^{9} \mathrm{yr}\right)$ begins a decay series that ultimately forms ${ }^{206} \mathrm{~Pb}$. The scene below depicts the relative number of ${ }^{238} \mathrm{U}$ atoms (red) and ${ }^{206} \mathrm{~Pb}$ atoms (green) in a mineral. If all the Pb comes from ${ }^{238} \mathrm{U}$, calculate the age of the sample.

24.105 Cosmologists modeling the origin of the elements postulate nuclides with very short half-lives. One of these nuclides, ${ }^{8} \operatorname{Be}\left(t_{1 / 2}=7 \times 10^{-17} \mathrm{~s}\right)$, plays a key role in stellar nucleosynthesis (p. 1099) because it must fuse with ${ }^{4} \mathrm{He}$ to form ${ }^{12} \mathrm{C}$ before decaying. Another explanation involves the simultaneous fusion of three ${ }^{4} \mathrm{He}$ nuclei to form ${ }^{12} \mathrm{C}$. Comment on the validity of this alternative mechanism.
24.106 Technetium-99m is a metastable nuclide used in numerous cancer diagnostic and treatment programs. It is prepared just before use because it decays rapidly through $\gamma$ emission:

$$
{ }^{99 \mathrm{~m}} \mathrm{Tc} \longrightarrow{ }^{99} \mathrm{Tc}+\gamma
$$

Use the data below to determine (a) the half-life of ${ }^{99 \mathrm{~m}} \mathrm{Tc}$; (b) the percentage of the isotope that is lost if it takes 2.0 h to prepare and administer the dose.

| Time (h) | $\boldsymbol{\gamma}$ Emission (photons/s) |
| :---: | :---: |
| 0 | 5000. |
| 4 | 3150. |
| 8 | 2000. |
| 12 | 1250. |
| 16 | 788 |
| 20 | 495 |

24.107 How many curies are produced by 1.0 mol of ${ }^{40} \mathrm{~K}\left(t_{1 / 2}=\right.$ $\left.1.25 \times 10^{9} \mathrm{yr}\right)$ ? How many becquerels?
24.108 The fraction of a radioactive isotope remaining at time $t$ is $\left(\frac{1}{2}\right)^{t / t_{1 / 2}}$, where $t_{1 / 2}$ is the half-life. If the half-life of carbon-14 is 5730 yr , what fraction of carbon-14 in a piece of charcoal remains after (a) 10.0 yr ; (b) $10.0 \times 10^{3} \mathrm{yr}$; (c) $10.0 \times 10^{4} \mathrm{yr}$ ?
(d) Why is radiocarbon dating more reliable for the fraction remaining in part (b) than that in part (a) or in part (c)?
24.109 The isotopic mass of ${ }_{86}^{210} \mathrm{Rn}$ is 209.989669 amu . When this nuclide decays by electron capture, it emits 2.368 MeV . What is the isotopic mass of the resulting nuclide?
24.110 Exactly 0.1 of the radioactive nuclei in a sample decay per hour. Thus, after $n$ hours, the fraction of nuclei remaining is $(0.900)^{n}$. Find the value of $n$ equal to one half-life.
24.111 In neutron activation analysis (NAA), stable isotopes are bombarded with neutrons. Depending on the isotope and the energy of the neutron, various emissions are observed. What are the products when the following neutron-activated species decay? Write an overall equation in shorthand notation for the reaction starting with the stable isotope before neutron activation.
(a) ${ }_{23}^{52} \mathrm{~V}^{*} \longrightarrow\left[\beta^{-}\right.$emission $]$
(b) ${ }_{29}^{64} \mathrm{Cu}^{*} \longrightarrow\left[\beta^{+}\right.$emission $]$
(c) ${ }_{13}^{28} \mathrm{Al}^{*} \longrightarrow\left[\beta^{-}\right.$emission $]$
24.112 In the 1950s, radioactive material was spread over the land from aboveground nuclear tests. A woman drinks some contaminated milk and ingests 0.0500 g of ${ }^{90} \mathrm{Sr}$, which is taken up by bones and teeth and not eliminated. (a) How much ${ }^{90} \mathrm{Sr}\left(t_{1 / 2}=\right.$ 29 yr ) is present in her body after 10 yr ? (b) How long will it take for $99.9 \%$ of the ${ }^{90}$ Sr to decay?
24.113 The scene below represents a reaction (with neutrons gray and protons purple) that occurs during the lifetime of a star. (a) Write a balanced nuclear equation for the reaction. (b) If the mass difference is $7.7 \times 10^{-2} \mathrm{amu}$, find the energy ( kJ ) released.

24.114 What volume of radon will be produced per hour at STP from 1.000 g of ${ }^{226} \mathrm{Ra}\left(t_{1 / 2}=1599 \mathrm{yr} ; 1 \mathrm{yr}=8766 \mathrm{~h}\right.$; mass of one ${ }^{226} \mathrm{Ra}$ atom $\left.=226.025402 \mathrm{amu}\right)$ ?
$24.115{ }^{90} \mathrm{Kr}\left(t_{1 / 2}=32 \mathrm{~s}\right)$ is used to study respiration. How soon after being made must a sample be administered to the patient if the activity must be at least $90 \%$ of the original activity?
24.116 Which isotope in each pair is more stable? Why?
(a) ${ }_{55}^{140} \mathrm{Cs}$ or ${ }_{55}^{133} \mathrm{Cs}$
(b) ${ }_{35}^{79} \mathrm{Br}$ or ${ }_{35}^{78} \mathrm{Br}$
(c) ${ }_{12}^{28} \mathrm{Mg}$ or ${ }_{12}^{24} \mathrm{Mg}$
(d) ${ }_{7}^{14} \mathrm{~N}$ or ${ }_{7}^{18} \mathrm{~N}$
24.117 A bone sample containing strontium-90 ( $\left.t_{1 / 2}=29 \mathrm{yr}\right)$ emits $7.0 \times 10^{4} \beta^{-}$particles per month. How long will it take for the emission to decrease to $1.0 \times 10^{4}$ particles per month?
24.118 The $23^{\text {rd }}$-century starship Enterprise uses a substance called "dilithium crystals" as its fuel.
(a) Assuming this material is the result of fusion, what is the product of the fusion of two ${ }^{6} \mathrm{Li}$ nuclei?
(b) How much energy is released per kilogram of dilithium formed? (Mass of one ${ }^{6} \mathrm{Li}$ atom is 6.015121 amu .)
(c) When four ${ }^{1} \mathrm{H}$ atoms fuse to form ${ }^{4} \mathrm{He}$, how many positrons are released?
(d) To determine the energy potential of the fusion processes in parts (b) and (c), compare the changes in mass per kilogram of dilithium and of ${ }^{4} \mathrm{He}$.
(e) Compare the change in mass per kilogram in part (b) to that for the formation of ${ }^{4} \mathrm{He}$ by the method used in current fusion reactors (see p. 1098). (For masses, see Problem 24.93.)
(f) Using early $21^{\text {st }}$-century fusion technology, how much tritium can be produced per kilogram of ${ }^{6} \mathrm{Li}$ in the following reaction: ${ }_{3}^{6} \mathrm{Li}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{2}^{4} \mathrm{He}+{ }_{1}^{3} \mathrm{H}$ ? When this amount of tritium is
fused with deuterium, what is the change in mass? How does this quantity compare with the use of dilithium in part (b)?
24.119 Uranium and radium are found in many rocky soils throughout the world. Both undergo radioactive decay, and one of the products is radon-222, the heaviest noble gas ( $t_{1 / 2}=$ 3.82 days). Inhalation of this gas contributes to many lung cancers. According to Environmental Protection Agency recommendations, the level of radioactivity from radon in homes should not exceed $4.0 \mathrm{pCi} / \mathrm{L}$ of air.
(a) What is the safe level of radon in $\mathrm{Bq} / \mathrm{L}$ of air?
(b) A home has a radon measurement of $41.5 \mathrm{pCi} / \mathrm{L}$. The owner vents the basement in such a way that no more radon enters the living area. What is the activity of the radon remaining in the room air (in $\mathrm{Bq} / \mathrm{L}$ ) after 9.5 days?
(c) How many more days does it take to reach the EPA recommended level?
24.120 Nuclear disarmament could be accomplished if weapons were not "replenished." The tritium in warheads decays to helium with a half-life of 12.26 yr and must be replaced or the weapon is useless. What fraction of the tritium is lost in 5.50 yr ?
24.121 A decay series starts with the synthetic isotope ${ }_{92}^{239} \mathrm{U}$. The first four steps are emissions of a $\beta^{-}$particle, another $\beta^{-}$, an $\alpha$ particle, and another $\alpha$. Write a balanced nuclear equation for each step. Which natural series could start by this sequence?
24.122 How long can a $54-\mathrm{lb}$ child be exposed to 1.0 mCi of radiation from ${ }^{222} \mathrm{Rn}$ before accumulating 1.0 mrad if the energy of each disintegration is 5.59 MeV ?
24.123 An earthquake in the area of present-day San Francisco is to be dated by measuring the ${ }^{14} \mathrm{C}$ activity $\left(t_{1 / 2}=5730 \mathrm{yr}\right)$ of parts of a tree uprooted during the event The weepartshayem activity of $12.9 \mathrm{~d} / \mathrm{min} \cdot \mathrm{g} \mathrm{C}$, and a living tree has an activity of $15.3 \mathrm{~d} / \mathrm{min} \cdot \mathrm{g} \mathrm{C}$. How long ago did the earthquake occur?
24.124 Were organisms a billion years ago exposed to more or less ionizing radiation than similar organisms today? Explain.
24.125 Tritium $\left({ }^{3} \mathrm{H} ; t_{1 / 2}=12.26 \mathrm{yr}\right)$ is continually formed in the upper troposphere by interaction of solar particles with nitrogen. As a result, natural waters contain a small amount of tritium. Two samples of wine are analyzed, one known to be made in 1941 and another made earlier. The water in the 1941 wine has 2.23 times as much tritium as the water in the other. When was the other wine produced?
24.126 Even though plutonium-239 $\left(t_{1 / 2}=2.41 \times 10^{4} \mathrm{yr}\right)$ is one of the main fission fuels, it is still a radiation hazard present in spent uranium fuel from nuclear power plants. How many years does it take for $99 \%$ of the plutonium-239 in spent fuel to decay?
24.127 Carbon from the remains of an extinct Australian marsupial, called Diprotodon, has a specific activity of $0.61 \mathrm{pCi} / \mathrm{g}$. Modern carbon has a specific activity of $6.89 \mathrm{pCi} / \mathrm{g}$. How long ago did the Diprotodon apparently become extinct?
24.128 The reaction that allows for radiocarbon dating is the continual formation of carbon-14 in the upper atmosphere:

$$
{ }_{7}^{14} \mathrm{~N}+{ }_{0}^{1} \mathrm{n} \longrightarrow{ }_{6}^{14} \mathrm{C}+{ }_{1}^{1} \mathrm{H}
$$

What is the energy change associated with this process in $\mathrm{eV} /$ reaction and in $\mathrm{kJ} / \mathrm{mol}$ reaction? (Masses of atoms: ${ }_{7}^{14} \mathrm{~N}=$ $14.003074 \mathrm{amu} ;{ }_{6}^{14} \mathrm{C}=14.003241 \mathrm{amu} ;{ }_{1}^{1} \mathrm{H}=1.007825 \mathrm{amu}$; mass of ${ }_{0}^{1} \mathrm{n}=1.008665 \mathrm{amu}$.)
24.129 What is the nuclear binding energy of a lithium-7 nucleus in units of $\mathrm{kJ} / \mathrm{mol}$ and $\mathrm{eV} /$ nucleus? (Mass of a lithium-7 atom $=$ 7.016003 amu.$)$
24.130 Gadolinium-146 undergoes electron capture. Identify the product, and use Figure 24.2 to find the modes of decay and the other two nuclides in the series below:

24.131 Using $21^{\text {st }}$-century technology, hydrogen fusion requires temperatures around $10^{8} \mathrm{~K}$. But, lower initial temperatures are used if the hydrogen is compressed. In the late $24^{\text {th }}$ century, the starship Leinad uses such methods to fuse hydrogen at $10^{6} \mathrm{~K}$.
(a) What is the kinetic energy of an H atom at $1.00 \times 10^{6} \mathrm{~K}$ ?
(b) How many H atoms are heated to $1.00 \times 10^{6} \mathrm{~K}$ from the energy of one H and one anti- H atom annihilating each other?
(c) If these H atoms fuse into ${ }^{4} \mathrm{He}$ atoms (with the loss of two positrons per ${ }^{4} \mathrm{He}$ formed), how much energy (in J ) is generated?
(d) How much more energy is generated by the fusion in (c) than by the hydrogen-antihydrogen collision in (b)?
(e) Should the captain of the Leinad change the technology and produce ${ }^{3} \mathrm{He}$ (mass $=3.01603 \mathrm{amu}$ ) instead of ${ }^{4} \mathrm{He}$ ?
24.132 A metastable (excited) form of ${ }^{50} \mathrm{Sc}$ changes to its stable form by emitting $\gamma$ radiation with a wavelength of 8.73 pm . What is the change in mass of 1 mol of the isotope when it undergoes this change?
24.133 A sample of cobalt-60 $\left(t_{1 / 2}=5.27 \mathrm{yr}\right)$, a powerful $\gamma$ emitter used to treat cancer, was purchased by a hospital on March 1, 2007. The sample must be replaced when its activity reaches $70 . \%$ of the original value. On what date must it be replaced?
24.134 Uranium-233 decays to thorium-229 by $\alpha$ decay, but the

Ereminssions have different energies and products: $83 \%$ emit an $\alpha$ particle with energy of 4.816 MeV and give ${ }^{229} \mathrm{Th}$ in its ground state; $15 \%$ emit an $\alpha$ particle of 4.773 MeV and give ${ }^{229} \mathrm{Th}$ in excited state I; and $2 \%$ emit a lower energy $\alpha$ particle and give ${ }^{229} \mathrm{Th}$ in the higher excited state II. Excited state II emits a $\gamma$ ray of 0.060 MeV to reach excited state I. (a) Find the $\gamma$-ray energy and wavelength that would convert excited state I to the ground state. (b) Find the energy of the $\alpha$ particle that would convert ${ }^{233} \mathrm{U}$ to excited state II.
24.135 Uranium-238 undergoes a slow decay step $\left(t_{1 / 2}=4.5 \times 10^{9}\right.$ $\mathrm{yr})$ followed by a series of fast steps to form the stable isotope ${ }^{206} \mathrm{~Pb}$. Thus, on a time scale of billions of years, ${ }^{238} \mathrm{U}$ effectively decays "directly" to ${ }^{206} \mathrm{~Pb}$, and the relative amounts of these isotopes are used to find the age of some rocks (see margin note, p. 1079). Two students derive equations relating number of halflives $(n)$ since the rock formed to the amounts of the isotopes:

Student 1:

$$
\left(\frac{1}{2}\right)^{n}=\frac{{ }^{238}}{{ }_{92} \mathrm{U}}{ }_{82} \mathrm{~Pb}
$$

Student 2:

$$
\left(\frac{1}{2}\right)^{n}=\frac{{ }_{92}^{238} \mathrm{U}}{{ }_{92}^{238} \mathrm{U}+{ }_{82}^{206} \mathrm{~Pb}}
$$

(a) Which equation is correct, and why?
(b) If a rock contains exactly twice as much ${ }^{238} \mathrm{U}$ as ${ }^{206} \mathrm{~Pb}$, what is its age in years?
24.136 In the naturally occurring thorium-232 decay series, the steps emit this sequence of particles: $\alpha, \beta^{-}, \beta^{-}, \alpha, \alpha, \alpha, \alpha, \beta^{-}$, $\beta^{-}$, and $\alpha$. Write a balanced equation for each step.
24.137 At death, a nobleman in ancient Egypt was mummified and his body contained $1.4 \times 10^{-3} \mathrm{~g}$ of ${ }^{40} \mathrm{~K}\left(t_{1 / 2}=1.25 \times 10^{9} \mathrm{yr}\right)$, $1.2 \times 10^{-8} \mathrm{~g}$ of ${ }^{14} \mathrm{C}\left(t_{1 / 2}=5730 \mathrm{yr}\right)$, and $4.8 \times 10^{-14} \mathrm{~g}$ of ${ }^{3} \mathrm{H}$
$\left(t_{1 / 2}=12.26 \mathrm{yr}\right)$. Which nuclide would give the most accurate estimate of the mummy's age? Explain.
24.138 Assuming that many radioactive nuclides can be considered safe after 20 half-lives, how long will it take for each of the following nuclides to be safe: (a) ${ }^{242} \mathrm{Cm}\left(t_{1 / 2}=163\right.$ days); (b) ${ }^{214} \mathrm{Po}\left(t_{1 / 2}=1.6 \times 10^{-4} \mathrm{~s}\right)$; (c) ${ }^{232} \mathrm{Th}\left(t_{1 / 2}=1.39 \times 10^{10} \mathrm{yr}\right)$ ?
24.139 An ancient sword has a blade from the early Roman Empire, around 100 AD , but the wooden handle, inlaid wooden decorations, leather ribbon, and leather sheath have different styles. Given the following activities, estimate the age of each part. Which part was made near the time of the blade ( $t_{1 / 2}$ of ${ }^{14} \mathrm{C}=$ $\left.5730 \mathrm{yr} ; \mathscr{A}_{0}=15.3 \mathrm{~d} / \mathrm{min} \cdot \mathrm{g}\right)$ ?

| Part | $\mathscr{A}_{t}(\mathrm{~d} / \mathrm{min} \cdot \mathrm{g})$ |
| :--- | :---: |
| Handle | 10.1 |
| Inlaid wood | 13.8 |
| Ribbon | 12.1 |
| Sheath | 15.0 |

24.140 The starship Voyager, like many other vessels of the newly designed $24^{\text {th }}$-century fleet, uses antimatter as fuel.
(a) How much energy is released when 1.00 kg each of antimatter and matter annihilate each other?
(b) When the antimatter is atomic antihydrogen, a small amount of it is mixed with excess atomic hydrogen (gathered from interstellar space during flight). The annihilation releases so much heat that the remaining hydrogen nuclei fuse to form ${ }^{4} \mathrm{He}$. If each hydrogen-antihydrogen collision releases enough heat to fuse $1.00 \times 10^{5}$ hydrogen atoms, how much energy (in kJ ) is released per kilogram of antihydrogen?

AOAgO PDE
(c) Which produces more energy per kilogram of antihydrogen, the procedure in part (a) or that in part (b)?
24.141 Use Einstein's equation, the mass in grams of 1 amu , and the relation between electron volts and joules to find the energy equivalent (in MeV ) of a mass difference of 1 amu .
24.142 Determine the age of a rock containing 0.065 g of uranium$238\left(t_{1 / 2}=4.5 \times 10^{9} \mathrm{yr}\right)$ and 0.023 g of lead-206. (Assume all the lead-206 came from ${ }^{238} \mathrm{U}$ decay.)
24.143 Plutonium-242 decays to uranium- 238 by emission of an $\alpha$ particle with an energy of 4.853 MeV . The ${ }^{238} \mathrm{U}$ that forms is unstable and emits a $\gamma$ ray $(\lambda=0.02757 \mathrm{~nm})$. (a) Write balanced equations for these reactions. (b) What would be the energy of the $\alpha$ particle if ${ }^{242} \mathrm{Pu}$ decayed directly to the more stable ${ }^{238} \mathrm{U}$ ?
24.144 Seaborgium-263 (Sg), the first isotope of element 106 synthesized, was made, together with four neutrons, by bombarding californium- 249 with oxygen-18. It then underwent a series of decays starting with three $\alpha$ emissions. Write balanced equations for the synthesis and the three $\alpha$ emissions of ${ }^{263} \mathrm{Sg}$.
24.145 Some nuclear power plants use plutonium-239, which is produced in breeder reactors (see margin note, p. 1097). The rate-determining step is the second $\beta^{-}$emission. How long does
it take to make 1.00 kg of ${ }^{239} \mathrm{Pu}$ if the reaction is complete when the product is $90 . \%{ }^{239} \mathrm{Pu}$ ?
24.146 A random-number generator can be used to simulate the probability of a given atom decaying over a given time. For example, the formula " $=\operatorname{RAND}($ )" in the Excel spreadsheet returns a random number between 0 and 1 ; thus, for one radioactive atom and a time of one half-life, a number less than 0.5 means the atom decays and a number greater than 0.5 means it doesn't.
(a) Place the " $=$ RAND () " formula in cells A1 to A10 of an Excel spreadsheet. In cell B1, place " $=\mathrm{IF}(\mathrm{A} 1<0.5,0,1)$." This formula returns 0 if A 1 is $<0.5$ (the atom decays) and 1 if A 1 is $>0.5$ (the atom does not decay). Place analogous formulas in cells B2 to B10 (using the "Fill Down" procedure in Excel). To determine the number of atoms remaining after one half-life, sum cells B1 to B10 by placing " $=\operatorname{SUM}(\mathrm{B} 1: \mathrm{B} 10)$ " in cell B12. To create a new set of random numbers, click on an empty cell (e.g., B13) and hit "Delete." Perform 10 simulations, each time recording the total number of atoms remaining. Do half of the atoms remain after each half-life? If not, why not?
(b) Increase the number of atoms to 100 by placing suitable formulas in cells A1 to A100, B1 to B100, and B102. Perform 10 simulations, and record the number of atoms remaining each time. Are these results more realistic for radioactive decay? Explain.
24.147 In the following Excel-based simulation, the fate of 256 atoms is followed over five half-lives. Set up formulas in columns A and B, as in Problem 24.146, and simulate the fate of the sample of 256 atoms over one half-life. Cells B1 to B256 should contain 1 or 0 . In cell C 1 , enter " $\mathrm{FF}\left(\mathrm{B}=\theta \mathrm{O}_{1}\right.$ RANP())." This returns 0 if the original atom decayed in the previous half-life or a random number between 0 and 1 if it did not. Fill the formula in C 1 down to cell C 256 . Column D should have formulas similar to those in B, but with modified references, as should columns F, H, and J. Columns E, G, and I should have formulas similar to those in C, but with modified references. In cell B258, enter " $=\operatorname{SUM}(\mathrm{B} 1: \mathrm{B} 256)$." This records the number of atoms remaining after the first half-life. Put formulas in cells D258, F258, H258, and J258 to record atoms remaining after subsequent half-lives.
(a) Ideally, how many atoms should remain after each half-life? (b) Make a table of the atoms remaining after each half-life in four separate simulations. Compare these outcomes to the ideal outcome. How would you make the results more realistic?
24.148 Representations of three nuclei (with neutrons gray and protons purple) are shown below. Nucleus 1 is stable, but 2 and 3 are not. (a) Write the symbol for each isotope. (b) What is (are) the most likely mode(s) of decay for 2 and 3 ?

## COMMON MATHEMATICAL OPERATIONS IN CHEMISTRY

|n addition to basic arithmetic and algebra, four mathematical operations are used frequently in general chemistry: manipulating logarithms, using exponential notation, solving quadratic equations, and graphing data. Each is discussed briefly below.

## MANIPULATING LOGARITHMS

## Meaning and Properties of Logarithms

A logarithm is an exponent. Specifically, if $x^{n}=A$, we can say that the logarithm to the base $x$ of the number $A$ is $n$, and we can denote it as

$$
\log _{x} A=n
$$

Because logarithms are exponents, they have the following properties:

$$
\begin{aligned}
\log _{x} 1 & =0 \\
\log _{x}(A \times B) & =\log _{x} A+\log _{x} B \\
\log _{x} \frac{A}{B} & =\log _{x} A-\log _{x} B \\
\log _{x} A & =y \log _{x} A \text { PDE Fnhancer }
\end{aligned}
$$

## Types of Logarithms

Common and natural logarithms are used frequently in chemistry and the other sciences. For common logarithms, the base ( $x$ in the examples above) is 10 , but they are written without specifying the base; that is, $\log _{10} A$ is written more simply as $\log A$. The common logarithm of 1000 is 3 ; in other words, you must raise 10 to the 3 rd power to obtain 1000 :

$$
\log 1000=3 \quad \text { or } \quad 10^{3}=1000
$$

Similarly, we have

| $\log 10$ | $=1$ |  | or | $10^{1}=10$ |
| ---: | :--- | ---: | :--- | ---: |
| $\log 1,000,000$ | $=6$ |  | or | $10^{6}=1,000,000$ |
| $\log 0.001$ | $=-3$ |  | or | $10^{-3}=0.001$ |
| $\log 853$ | $=2.931$ |  | or | $10^{2.931}=853$ |

The last example illustrates an important point about significant figures with all logarithms: the number of significant figures in the number equals the number of digits to the right of the decimal point in the logarithm. That is, the number 853 has three significant figures, and the logarithm 2.931 has three digits to the right of the decimal point.

To find a common logarithm with an electronic calculator, you simply enter the number and press the LOG button.

For natural logarithms, the base is the number $e$, which is $2.71828 \ldots$, and $\log _{e} A$ is written $\ln A$. The relationship between the common and natural logarithms is easily obtained: because

$$
\log 10=1 \quad \text { and } \quad \ln 10=2.303
$$

Therefore, we have

$$
\ln A=2.303 \log A
$$

To find a natural logarithm with an electronic calculator, you simply enter the number and press the LN button. If your calculator does not have an LN button, enter the number, press the LOG button, and multiply by 2.303 .

## Antilogarithms

The antilogarithm is the number you obtain when you raise the base to the logarithm: antilogarithm (antilog) of $n$ is $10^{n}$
Using two of the earlier examples, the antilog of 3 is 1000 , and the antilog of 2.931 is 853 . To obtain the antilog with a calculator, you enter the number and press the $10^{x}$ button. Similarly, to obtain the natural antilogarithm, you enter the number and press the $e^{x}$ button. [On some calculators, you enter the number and first press INV and then the LOG (or LN ) button.]

## USING EXPONENTIAL (SCIENTIFIC) NOTATION

Many quantities in chemistry are very large or very small. For example, in the conventional way of writing numbers, the number of gold atoms in 1 gram of gold is
$59,060,000,000,000,000,000,000$ atoms (to four significant figures)
As another example, the mass in grams of one gold atom is
0.0000000000000000000003272 g (to four significant figures)

Exponential (scientific) notation provides a much more practical way of writing such numbers In exponential notation, we express numbers in the form
where $A$ (the coefficient) is greater than or equal to 1 and less than 10 (that is, $1 \leq A<10$ ), and $n$ (the exponent) is an integer.

If the number we want to express in exponential notation is larger than 1 , the exponent is positive $(n>0)$; if the number is smaller than 1 , the exponent is negative $(n<0)$. The size of $n$ tells the number of places the decimal point (in conventional notation) must be moved to obtain a coefficient $A$ greater than or equal to 1 and less than 10 (in exponential notation). In exponential notation, 1 gram of gold contains $5.906 \times 10^{22}$ atoms, and each gold atom has a mass of $3.272 \times 10^{-22} \mathrm{~g}$.

## Changing Between Conventional and Exponential Notation

In order to use exponential notation, you must be able to convert to it from conventional notation, and vice versa.

1. To change a number from conventional to exponential notation, move the decimal point to the left for numbers equal to or greater than 10 and to the right for numbers between 0 and 1:
$75,000,000$ changes to $7.5 \times 10^{7}$ (decimal point 7 places to the left)
0.006042 changes to $6.042 \times 10^{-3}$ (decimal point 3 places to the right)
2. To change a number from exponential to conventional notation, move the decimal point the number of places indicated by the exponent to the right for numbers with positive exponents and to the left for numbers with negative exponents:
$1.38 \times 10^{5}$ changes to 138,000 (decimal point 5 places to the right)
$8.41 \times 10^{-6}$ changes to 0.00000841 (decimal point 6 places to the left)
3. An exponential number with a coefficient greater than 10 or less than 1 can be changed to the standard exponential form by converting the coefficient to the standard form and adding the exponents:

$$
\begin{gathered}
582.3 \times 10^{6} \text { changes to } 5.823 \times 10^{2} \times 10^{6}=5.823 \times 10^{(2+6)}=5.823 \times 10^{8} \\
0.0043 \times 10^{-4} \text { changes to } 4.3 \times 10^{-3} \times 10^{-4}=4.3 \times 10^{[(-3)+(-4)]}=4.3 \times 10^{-7}
\end{gathered}
$$

## Using Exponential Notation in Calculations

In calculations, you can treat the coefficient and exponents separately and apply the properties of exponents (see earlier section on logarithms).

1. To multiply exponential numbers, multiply the coefficients, add the exponents, and reconstruct the number in standard exponential notation:

$$
\begin{aligned}
\left(5.5 \times 10^{3}\right)\left(3.1 \times 10^{5}\right) & =(5.5 \times 3.1) \times 10^{(3+5)}=17 \times 10^{8}=1.7 \times 10^{9} \\
\left(9.7 \times 10^{14}\right)\left(4.3 \times 10^{-20}\right) & =(9.7 \times 4.3) \times 10^{[14+(-20)]}=42 \times 10^{-6}=4.2 \times 10^{-5}
\end{aligned}
$$

2. To divide exponential numbers, divide the coefficients, subtract the exponents, and reconstruct the number in standard exponential notation:

$$
\begin{aligned}
& \frac{2.6 \times 10^{6}}{5.8 \times 10^{2}}= \frac{2.6}{5.8} \times 10^{(6-2)}=0.45 \times 10^{4}=4.5 \times 10^{3} \\
& \frac{1.7 \times 10^{-5}}{8.2 \times 10^{-8}}=\frac{1.7}{8.2} \times 10^{[(-5)-(-8)]}=0.21 \times 10^{3}=2.1 \times 10^{2}
\end{aligned}
$$

3. To add or subtract exponential numbers, change all numbers so that they have the same exponent, then add or subtract the coefficients:

$$
\begin{aligned}
\left(1.45 \times 10^{4}\right)+\left(3.2 \times 10^{3}\right) & =\left(1.45 \times 10^{4}\right)+\left(0.32 \times 10^{4}\right)=1.77 \times 10^{4} \\
\left(3.22 \times 10^{5}\right)-\left(9.02 \times 10^{4}\right) & =\left(3.22 \times 10^{5}\right)-\left(0.902 \times 10^{5}\right)=2.32 \times 10^{5}
\end{aligned}
$$

## SOLVING QUADRATIC EQBATIONS PDF Enhancer

A quadratic equation is one in which the highest power of $x$ is 2 . The general form of a quadratic equation is

$$
a x^{2}+b x+c=0
$$

where $a, b$, and $c$ are numbers. For given values of $a, b$, and $c$, the values of $x$ that satisfy the equation are called solutions of the equation. We calculate $x$ with the quadratic formula:

$$
x=\frac{-b \pm \sqrt{b^{2}-4 a c}}{2 a}
$$

We commonly require the quadratic formula when solving for some concentration in an equilibrium problem. For example, we might have an expression that is rearranged into the quadratic equation

$$
4.3 x^{2}+0.65 x-8.7=0
$$

Applying the quadratic formula, with $a=4.3, b=0.65$, and $c=-8.7$, gives

$$
x=\frac{-0.65 \pm \sqrt{(0.65)^{2}-4(4.3)(-8.7)}}{2(4.3)}
$$

The "plus or minus" sign ( $\pm$ ) indicates that there are always two possible values for $x$. In this case, they are

$$
x=1.3 \quad \text { and } \quad x=-1.5
$$

In any real physical system, however, only one of the values will have any meaning. For example, if $x$ were $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$, the negative value would mean a negative concentration, which has no meaning.

## GRAPHING DATA IN THE FORM OF A STRAIGHT LINE

Visualizing changes in variables by means of a graph is a very useful technique in science. In many cases, it is most useful if the data can be graphed in the form of a straight line. Any equation will appear as a straight line if it has, or can be rearranged to have, the following general form:

$$
y=m x+b
$$

where $y$ is the dependent variable (typically plotted along the vertical axis), $x$ is the independent variable (typically plotted along the horizontal axis), $m$ is the slope of the line, and $b$ is the intercept of the line on the $y$ axis. The intercept is the value of $y$ when $x=0$ :

$$
y=m(0)+b=b
$$

The slope of the line is the change in $y$ for a given change in $x$ :

$$
\text { Slope }(m)=\frac{y_{2}-y_{1}}{x_{2}-x_{1}}=\frac{\Delta y}{\Delta x}
$$

The sign of the slope tells the direction of the line. If $y$ increases as $x$ increases, $m$ is positive, and the line slopes upward with higher values of $x$; if $y$ decreases as $x$ increases, $m$ is negative, and the line slopes downward with higher values of $x$. The magnitude of the slope indicates the steepness of the line. A line with $m=3$ is three times as steep ( $y$ changes three times as much for a given change in $x$ ) as a line with $m=1$.

Consider the linear equation $y=2 x+1$. A graph of this equation is shown in Figure A.1. In practice, you can find the slope by drawing a right triangle to the line, using the line as the hypotenuse. Then, one leg gives $\Delta y$, and the other gives $\Delta x$. In the figure, $\Delta y=8$ and $\Delta x=4$.
At Alyeral places in the text, anequation is rearranged into the form of a stratght lime in order to determine information from the slope and/or the intercept. For example, in Chapter 16, we obtained the following expression:

$$
\ln \frac{[A]_{0}}{[A]_{t}}=k t
$$

Based on the properties of logarithms, we have

$$
\ln [A]_{0}-\ln [A]_{t}=k t
$$

Rearranging into the form of an equation for a straight line gives

$$
\begin{aligned}
\ln [A]_{t} & =-k t+\ln [A]_{0} \\
y & =m x+b
\end{aligned}
$$

Thus, a plot of $\ln [A]_{t}$ vs. $t$ is a straight line, from which you can see that the slope is $-k$ (the negative of the rate constant) and the intercept is $\ln [A]_{0}$ (the natural logarithm of the initial concentration of $A$ ).

At many other places in the text, linear relationships occur that were not shown in graphical terms. For example, the conversion of temperature scales in Chapter 1 can also be expressed in the form of a straight line:

$$
\begin{aligned}
& { }^{\circ} \mathrm{F}=\frac{9}{5}{ }^{\circ} \mathrm{C}+32 \\
& y=m x+b
\end{aligned}
$$

## APPENDIX C

## EQUILIBRIUM CONSTANTS FOR SELECTED SUBSTANCES*

## Dissociation (lonization) Constants $\left(K_{\mathrm{a}}\right)$ of Selected Acids

[^41](continued)

## A-8

## Dissociation (lonization) Constants ( $K_{\mathrm{a}}$ ) of Selected Acids

| Name and Formula | Lewis Structure | $K_{\mathrm{a}}$ | $K_{\mathrm{a} 1}$ |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |

## Dissociation (lonization) Constants ( $K_{\mathrm{a}}$ ) of Selected Acids (continued)

| Name and Formula | Lewis Structure ${ }^{\dagger}$ | $K_{\text {a1 }}$ | $K_{\text {a2 }}$ | $K_{\text {a3 }}$ |
| :---: | :---: | :---: | :---: | :---: |
| Malonic acid $\mathrm{HOOCCH}_{2} \mathrm{COOH}$ |  | $1.4 \times 10^{-3}$ | $2.0 \times 10^{-6}$ |  |
| Nitrous acid $\mathrm{HNO}_{2}$ | $\mathrm{H}-\mathrm{O}-\ddot{\mathrm{N}}=\ddot{O}$ | $7.1 \times 10^{-4}$ |  |  |
| Oxalic acid <br> HOOCCOOH |  | $5.6 \times 10^{-2}$ | $5.4 \times 10^{-5}$ |  |
| Phenol $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}$ |  | $1.0 \times 10^{-10}$ |  |  |
| Phenylacetic acid $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{CH}_{2} \mathrm{COOH}$ |  | $4.9 \times 10^{-5}$ |  |  |
| Phosphoric acid $\mathrm{H}_{3} \mathrm{PO}_{4}$ |  | Fnhangerior | $6.3 \times 10^{-8}$ | $4.2 \times 10^{-13}$ |
| Phosphorous acid $\mathrm{HPO}(\mathrm{OH})_{2}$ |  | $3 \times 10^{-2}$ | $1.7 \times 10^{-7}$ |  |
| Propanoic acid $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{COOH}$ |  | $1.3 \times 10^{-5}$ |  |  |
| Pyruvic acid $\mathrm{CH}_{3} \mathrm{C}(\mathrm{O}) \mathrm{COOH}$ |  | $2.8 \times 10^{-3}$ |  |  |
| Succinic acid $\mathrm{HOOCCH}_{2} \mathrm{CH}_{2} \mathrm{COOH}$ |  | $6.2 \times 10^{-5}$ | $2.3 \times 10^{-6}$ |  |
| Sulfuric acid $\mathrm{H}_{2} \mathrm{SO}_{4}$ |  | Very large | $1.0 \times 10^{-2}$ |  |
| Sulfurous acid $\mathrm{H}_{2} \mathrm{SO}_{3}$ |  | $1.4 \times 10^{-2}$ | $6.5 \times 10^{-8}$ |  |

Dissociation (lonization) Constants $\left(K_{b}\right)$ of Selected Amine Bases

| Name and Formula | Lewis Structure ${ }^{\dagger}$ | $K_{\text {b1 }} \quad K_{\text {b2 }}$ |
| :---: | :---: | :---: |
| Ammonia $\mathrm{NH}_{3}$ |  | $1.76 \times 10^{-5}$ |
| Aniline $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}$ |  | $4.0 \times 10^{-10}$ |
| Diethylamine $\left(\mathrm{CH}_{3} \mathrm{CH}_{2}\right)_{2} \mathrm{NH}$ |  | $8.6 \times 10^{-4}$ |
| Dimethylamine $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}$ |  | $5.9 \times 10^{-4}$ |
| Ethanolamine $\mathrm{HOCH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}$ |  | $3.2 \times 10^{-5}$ |
| Ethylamine $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{NH}_{2}$ |  | $\text { PDF } \stackrel{4.3 \times 10^{-4}}{\text { Enhancer }}$ |
| Ethylenediamine $\mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}$ |  | $8.5 \times 10^{-5} \quad 7.1 \times 10^{-8}$ |
| Methylamine $\mathrm{CH}_{3} \mathrm{NH}_{2}$ |  | $4.4 \times 10^{-4}$ |
| tert-Butylamine $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CNH}_{2}$ |  | $4.8 \times 10^{-4}$ |
| Piperidine $\mathrm{C}_{5} \mathrm{H}_{10} \mathrm{NH}$ |  | $1.3 \times 10^{-3}$ |
| n-Propylamine $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}$ |  | $3.5 \times 10^{-4}$ |

[^42]Dissociation (lonization) Constants ( $K_{\mathrm{b}}$ ) of Selected Amine Bases (continued)

| Name and Formula | Lewis Structure $^{\dagger}$ | $K_{\mathrm{b} 1}$ | $K_{\mathrm{b} 2}$ |  |
| :--- | :---: | :---: | :---: | :---: |
|  | $\mathrm{H} \mathrm{H}-\mathrm{N}-\mathrm{H}$ | H |  |  |
| Isopropylamine | $\mathrm{H}-\mathrm{C}$ | C | $\mathrm{C}-\mathrm{H}$ | $4.7 \times 10^{-4}$ |
| $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHNH}_{2}$ | H | H | H |  |
|  |  |  |  |  |

1,3-Propylenediamine $\mathrm{H}_{2} \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}$

$3.1 \times 10^{-4} \quad 3.0 \times 10^{-6}$

Pyridine
$\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}$

$1.7 \times 10^{-9}$

Triethylamine $\left(\mathrm{CH}_{3} \mathrm{CH}_{2}\right)_{3} \mathrm{~N}$

## Dissociation (Ionization) Constants $\left(K_{\mathrm{a}}\right)$ of Some Hydrated Metal Ions

| Free <br> lon | Hydrated <br> lon | $\boldsymbol{K}_{\mathbf{a}}$ |
| :--- | :--- | :---: |
| $\mathrm{Fe}^{3+}$ | $\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{3+}(a q)$ | $6 \times 10^{-3}$ |

## APPENDIX E

## ANSWERS TO SELECTED PROBLEMS

## Chapter 1

1.2 Gas molecules fill the entire container; the volume of a gas is the volume of the container. Solids and liquids have a definite volume. The volume of the container does not affect the volume of a solid or liquid. (a) gas (b) liquid (c) liquid 1.4 Physical property: a characteristic shown by a substance itself, without any interaction with or change into other substances. Chemical property: a characteristic of a substance that appears as it interacts with, or transforms into, other substances. (a) Color (yellow-green and silvery to white) and physical state (gas and metal to crystals) are physical properties. The interaction between chlorine gas and sodium metal is a chemical property.
(b) Color and magnetism are physical properties. No chemical changes. 1.6(a) Physical change; there is only a temperature change. (b) Chemical change; the change in appearance indicates an irreversible chemical change. (c) Physical change; there is only a change in size, not composition. (d) Chemical change; the wood (and air) become different substances with different compositions. 1.8(a) fuel (b) wood 1.13 Lavoisier measured the total mass of the reactants and products, not just the mass of the solids. The total mass of the reactants and products remained constant. His measurements $\$$ oued that agas was involved in the reaction. He called this gas oxygen (one of his key discoveries). 1.16 A well-designed experiment must have the following essential features: (1) There must be at least two variables that are expected to be related; (2) there must be a way to control all the variables, so that only one at a time may be changed; (3) the results must be reproducible. $\quad 1.19(\mathrm{a})(2.54 \mathrm{~cm})^{2} /$ $(1 \mathrm{in})^{2}$ and $(1 \mathrm{~m})^{2} /(100 \mathrm{~cm})^{2} \quad$ (b) $(1000 \mathrm{~m})^{2} /(1 \mathrm{~km})^{2}$ and $(100 \mathrm{~cm})^{2} /(1 \mathrm{~m})^{2} \quad$ (c) $\left(1.609 \times 10^{3} \mathrm{~m} / \mathrm{mi}\right)$ and $(1 \mathrm{~h} / 3600 \mathrm{~s})$ (d) $(1000 \mathrm{~g} / 2.205 \mathrm{lb})$ and $\left(3.531 \times 10^{-5} \mathrm{ft}^{3} / \mathrm{cm}^{3}\right)$ 1.21 An extensive property depends on the amount of material present. An intensive property is the same regardless of how much material is present. ## Chapter 2

2.1 Compounds contain different types of atoms; there is only one type of atom in an element. 2.4(a) The presence of more than one element makes pure calcium chloride a compound.
(b) There is only one kind of atom, so sulfur is an element.
(c) The presence of more than one compound makes baking powder a mixture. (d) The presence of more than one type of atom means cytosine cannot be an element. The specific, not variable, arrangement means it is a compound. 2.12(a) elements, compounds, and mixtures (b) compounds (c) compounds 2.14(a) Law of definite composition: the composition is the same regardless of its source. (b) Law of mass conservation: the total quantity of matter does not change. (c) Law of multiple proportions: two elements can combine to form two different compounds that have different proportions of those elements. 2.16(a) No, the percent by mass of each element in a compound is fixed. (b) Yes, the mass of each element in a compound depends on the mass of the compound. 2.18 The two experiments demonstrate the law of definite composition. The unknown compound decomposes the same way both times. The experiments also demonstrate the law of conservation of mass since the total mass before reaction equals the total mass after reaction. $\quad \mathbf{2 . 2 0}$ (a) 1.34 g F (b) 0.514 Ca ; 0.486 F (c) 51.4 mass $\% \mathrm{Ca}$; 48.6 mass $\% \mathrm{~F}$ 2.22(a) 0.603 (b) $322 \mathrm{~g} \mathrm{Mg} \quad 2.243 .498 \times 10^{6} \mathrm{~g} \mathrm{Cu} ; 1.766 \times 10^{6} \mathrm{~g} \mathrm{~S}$ 2.26 compound $1: 0.905 \mathrm{~S} / \mathrm{Cl}$; compound 2: $0.451 \mathrm{~S} / \mathrm{Cl}$; ratio: 2.00/1.00 2.29 Coal A 2.31 Dalton postulated that atoms of an element are identical and that compounds result from the chemical combination of specific ratios of different elements. 2.32 If you know the ratio of any two quantities and the value of
 charge and the charge-to-mass ratio were known. 2.36 The identity of an element is based on the number of protons, not the number of neutrons. The mass number can vary (by a change in number of neutrons) without changing the identity of the element. 2.39 All three isotopes have 18 protons and 18 electrons. Their respective mass numbers are 36,38 , and 40 , with the respective numbers of neutrons being 18, 20, and 22. 2.41(a) These have the same number of protons and electrons, but different numbers of neutrons; same Z. (b) These have the same number of neutrons, but different numbers of protons and electrons; same $N$. (c) These have different numbers of protons, neutrons, and electrons; same A. 2.43(a) ${ }_{18}^{38} \mathrm{Ar}$ (b) ${ }_{25}^{55} \mathrm{Mn} \quad$ (c) ${ }_{47}^{109} \mathrm{Ag}$ 2.45(a) ${ }_{22}^{48} \mathrm{Ti}$
(b) ${ }_{34} \mathrm{Se}$
(c) ${ }_{5}^{11} \mathrm{~B}$

$2.4769 .72 \mathrm{amu} \quad 2.49{ }^{35} \mathrm{Cl}=75.774 \%,{ }^{37} \mathrm{Cl}=24.226 \%$ 2.52(a) In the modern periodic table, the elements are arranged in order of increasing atomic number. (b) Elements in a group (or family) have similar chemical properties. (c) Elements can be classified as metals, metalloids, or nonmetals. 2.55 The alkali metals [Group $1 \mathrm{~A}(1)$ ] are metals and readily lose one electron to form cations; the halogens [Group 7A(17)] are nonmetals and
readily gain one electron to form anions. 2.56(a) germanium; Ge; 4A(14); metalloid (b) phosphorus; P; 5A(15); nonmetal (c) helium; He ; 8A(18); nonmetal (d) lithium; Li; 1A(1); metal (e) molybdenum; Mo; 6B(6); metal 2.58(a) Ra; 88 (b) Si; 14 (c) $\mathrm{Cu} ; 63.55$ (d) $\mathrm{Br} ; 79.90 \quad$ 2.60 Atoms of these two kinds of substances will form ionic bonds, in which one or more electrons are transferred from the metal atom to the nonmetal atom to form a cation and an anion, respectively. $\quad 2.63$ Coulomb's law states the energy of attraction in an ionic bond is directly proportional to the product of charges and inversely proportional to the distance between charges. The product of charges in $\mathrm{MgO}[(2+)(2-)]$ is greater than that in $\mathrm{LiF}[(1+)(1-)]$. Thus, MgO has stronger ionic bonding. 2.66 The Group $1 \mathrm{~A}(1)$ elements form cations, and the Group 7A(17) elements form anions. 2.68 Each potassium atom loses one electron to form an ion with a $1+$ charge. Each sulfur atom gains two electrons to form an ion with a $2-$ charge. Two potassiums, giving one electron each, are required for each sulfur, which takes two electrons. The oppositely charged ions attract each other to form an ionic solid, $\mathrm{K}_{2} \mathrm{~S}$. $2.70 \mathrm{~K}^{+} ; \mathrm{I}^{-} \quad$ 2.72(a) oxygen; 17; 6A(16); 2 (b) fluorine; 19; 7A(17); 2 (c) calcium; 40; 2A(2); 4 2.74 Lithium forms the $\mathrm{Li}^{+}$ion; oxygen forms the $\mathrm{O}^{2-}$ ion. Number of $\mathrm{O}^{2-}$ ions $=$ $4.2 \times 10^{21} \mathrm{O}^{2-}$ ions. $\quad 2.76 \mathrm{NaCl} \quad 2.78 \mathrm{An}$ empirical formula shows the simplest ratio of atoms of each element present in a compound, whereas a molecular formula describes the type and actual number of atoms of each element in a molecule of the compound. The empirical formula and the molecular formula can be the same. The molecular formula is always a whole-number multiple of the empirical formula. 2.80 The two samples are simpery ind lion hydrogen atoms. They differ in that they contain different types of molecules: $\mathrm{H}_{2} \mathrm{O}_{2}$ molecules in the hydrogen peroxide sample, and $\mathrm{H}_{2}$ and $\mathrm{O}_{2}$ molecules in the mixture. In addition, the mixture contains 20 billion molecules ( 10 billion $\mathrm{H}_{2}$ and 10 billion $\mathrm{O}_{2}$ ), while the hydrogen peroxide sample contains 10 billion molecules. 2.84 (a) $\mathrm{NH}_{2}$ (b) $\mathrm{CH}_{2} \mathrm{O} \quad$ 2.86(a) $\mathrm{Na}_{3} \mathrm{~N}$, sodium nitride (b) SrO , strontium oxide (c) $\mathrm{AlCl}_{3}$, aluminum chloride 2.88(a) $\mathrm{MgF}_{2}$, magnesium fluoride (b) ZnS , zinc sulfide $\begin{array}{lll}\text { (c) } \mathrm{SrCl}_{2} \text {, strontium chloride } 2.90 \text { (a) } \mathrm{SnCl}_{4} & \text { (b) iron(III) bro- }\end{array}$ mide (c) CuBr (d) manganese(III) oxide 2.92(a) cobalt(II) oxide (b) $\mathrm{Hg}_{2} \mathrm{Cl}_{2}$ (c) lead(II) acetate trihydrate (d) $\mathrm{Cr}_{2} \mathrm{O}_{3}$ 2.94(a) BaO (b) $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{2}$ (c) MgS 2.96(a) $\mathrm{H}_{2} \mathrm{SO}_{4}$; sulfuric acid (b) $\mathrm{HIO}_{3}$; iodic acid (c) HCN ; hydrocyanic acid (d) $\mathrm{H}_{2} \mathrm{~S}$; hydrosulfuric acid 2.98(a) ammonium ion, $\mathrm{NH}_{4}{ }^{+}$; ammonia, $\mathrm{NH}_{3}$ (b) magnesium sulfide, MgS ; magnesium sulfite, $\mathrm{MgSO}_{3}$; magnesium sulfate, $\mathrm{MgSO}_{4}$ (c) hydrochloric acid, HCl ; chloric acid, $\mathrm{HClO}_{3}$; chlorous acid, $\mathrm{HClO}_{2}$ (d) cuprous bromide, CuBr ; cupric bromide, $\mathrm{CuBr}_{2} \quad$ 2.100 Disulfur tetrafluoride, $\mathrm{S}_{2} \mathrm{~F}_{4}$ 2.102 (a) calcium chloride (b) copper(I) oxide (c) stannic fluoride (d) hydrochloric acid 2.104(a) 12 oxygen atoms; 342.2 amu (b) 9 hydrogen atoms; 132.06 amu (c) 8 oxygen atoms; $344.6 \mathrm{amu} \quad 2.106(\mathrm{a})\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4} ; 132.15 \mathrm{amu} \quad$ (b) $\mathrm{NaH}_{2} \mathrm{PO}_{4}$; 119.98 amu (c) $\mathrm{KHCO}_{3} ; 100.12 \mathrm{amu} \quad 2.108$ (a) 108.02 amu (b) 331.2 amu (c) $72.08 \mathrm{amu} \quad$ 2.110(a) $\mathrm{SO}_{3}$; sulfur trioxide; 80.07 amu (b) $\mathrm{C}_{3} \mathrm{H}_{8}$; propane; $44.09 \mathrm{amu} \quad 2.112$ disulfur dichloride; $\mathrm{SCl} ; 135.04 \mathrm{amu}$ 2.116 Separating the components of a mixture requires physical methods only; that is, no chemical changes (no changes in composition) take place, and the components maintain their chemical identities and properties
throughout. Separating the components of a compound requires a chemical change (change in composition). $\quad 2.119$ (a) compound (b) homogeneous mixture (c) heterogeneous mixture (d) homogeneous mixture (e) homogeneous mixture 2.121(a) Salt dissolves in water and pepper does not. Procedure: Add water to mixture; filter to remove solid pepper. Evaporate water to recover solid salt. (b) Sugar dissolves in water and sand does not. Procedure: Add water to mixture; filter to remove sand. Evaporate water to recover sugar. (c) Oil is less volatile (lower tendency to vaporize to a gas) than water. Procedure: Separate the components by distillation (boiling), and condense the water from vapor thus leaving the oil in the distillation flask. (d) Vegetable oil and vinegar (solution of acetic acid in water) are not soluble in each other. Procedure: allow mixture to separate into two layers and drain off the lower (denser) layer. 2.123(a) filtration (b) extraction or chromatography (c) extraction and filtration 2.125(a) fraction of volume $=5.2 \times 10^{-13} \quad$ (b) mass of nucleus $=6.64466 \times 10^{-24} \mathrm{~g}$; fraction of mass $=0.999726$ 2.126 strongest ionic bonding: MgO; weakest ionic bonding: RbI 2.1302 .7 mass $\% \mathrm{Fe} ; 2.4$ mass $\% \mathrm{Mg} ; 43.2$ mass $\% \mathrm{Si} ; 51.6$ mass \% O 2.133(a) I = NO; II $=\mathrm{N}_{2} \mathrm{O}_{3} ;$ III $=\mathrm{N}_{2} \mathrm{O}_{5}$ (b) I has 1.14 g O per $1.00 \mathrm{~g} \mathrm{~N} ; \mathrm{II}, 1.71 \mathrm{~g} \mathrm{O}$; III, $2.86 \mathrm{~g} \mathrm{O} \quad 2.139$ (a) $\mathrm{Cl}^{-}$, 1.898 mass $\% ; \mathrm{Na}^{+}, 1.056$ mass $\% ; \mathrm{SO}_{4}{ }^{2-}, 0.265$ mass $\%$; $\mathrm{Mg}^{2+}, 0.127$ mass $\% ; \mathrm{Ca}^{2+}, 0.04$ mass $\% ; \mathrm{K}^{+}, 0.038$ mass $\%$; $\mathrm{HCO}_{3}{ }^{-}, 0.014$ mass $\%$ (b) $30.72 \%$ (c) Alkaline earth metal ions, total mass $\%=0.17 \%$; alkali metal ions, total mass $\%=$ $1.094 \%$ (d) Anions ( 2.177 mass \%) make up a larger mass fraction than cations ( 1.26 mass \%). $\quad 2.142$ Molecular, $\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{O}_{4}$; empirical, $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$; molecular mass, $118.09 \mathrm{amu} ; 40.68 \%$ by mass C; $5.122 \%$ by mass $\mathrm{H} ; 54.20 \%$ bymass $\mathrm{C}^{2} .144 \mathrm{~B} D \mathrm{P}$; $44.05 \mathrm{amu} \quad 2.146$ (a) Formulas and masses in amu: ${ }^{5} \mathrm{~N}_{2}{ }^{48} \mathrm{O}, 48$; ${ }^{15} \mathrm{~N}_{2}{ }^{16} \mathrm{O}, 46 ;{ }^{14} \mathrm{~N}_{2}{ }^{18} \mathrm{O}, 46 ;{ }^{14} \mathrm{~N}_{2}{ }^{16} \mathrm{O}, 44 ;{ }^{15} \mathrm{~N}^{14} \mathrm{~N}{ }^{18} \mathrm{O}, 47$; ${ }^{15} \mathrm{~N}^{14} \mathrm{~N}^{16} \mathrm{O}, 45 \quad$ (b) ${ }^{15} \mathrm{~N}_{2}{ }^{18} \mathrm{O}$, least common; ${ }^{14} \mathrm{~N}_{2}{ }^{16} \mathrm{O}$, most common $\quad 2.14958 .091 \mathrm{amu} \quad 2.151$ nitroglycerin, 39.64 mass \% NO; isoamyl nitrate, 22.54 mass \% NO. $\quad \mathbf{2 . 1 5 2} 0.370 \mathrm{lb} \mathrm{C}$; $0.0222 \mathrm{lb} \mathrm{H} ; 0.423 \mathrm{lb} \mathrm{O} ; 0.185 \mathrm{lb} \mathrm{N} \quad$ 2.156(a) 20.39 mass $\% ~ \mathrm{Mg}$ (b) 12.84 mass $\% \mathrm{Mg} \quad$ (c) $x=2 \quad 2.159(1)$ chemical change (2) physical change (3) chemical change (4) chemical change (5) physical change

## Chapter 4

4.2 Ionic or polar covalent compounds 4.3 Ions must be present, and they come from ionic compounds or from electrolytes such as acids and bases. 4.6(2) 4.10(a) Benzene is likely to be insoluble in water because it is nonpolar and water is polar. (b) Sodium hydroxide, an ionic compound, is likely to be very soluble in water. (c) Ethanol $\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}\right)$ is likely to be soluble in water because the alcohol group ( -OH ) will hydrogen bond with a water molecule. (d) Potassium acetate, an ionic compound, is likely to be very soluble in water.
4.12(a) Yes, CsBr is a soluble salt. (b) Yes, HI is a strong acid. 4.14(a) 0.64 mol (b) 0.242 mol (c) $1.18 \times 10^{-4} \mathrm{~mol}$
4.16(a) 3.0 mol
(b) $7.57 \times 10^{-5} \mathrm{~mol}$
(c) $0,148 \mathrm{~mol}$
4.18(a) $0.058 \mathrm{~mol} \mathrm{Al}{ }^{3+} ; 3.5 \times 10^{22} \mathrm{Al}^{3+}{ }^{\text {ons }}$ ion 98 คel $\mathrm{Cl}^{-} ;$PDE $1.1 \times 10^{23} \mathrm{Cl}^{-}$ions (b) $4.62 \times 10^{-4} \mathrm{~mol} \mathrm{Li}^{+} ; 2.78 \times 10^{20} \mathrm{Li}^{+}$ ions; $2.31 \times 10^{-4} \mathrm{~mol} \mathrm{SO}_{4}{ }^{2-} ; 1.39 \times 10^{20} \mathrm{SO}_{4}{ }^{2-}$ ions (c) $1.50 \times 10^{-2} \mathrm{~mol} \mathrm{~K}^{+} ; 9.02 \times 10^{21} \mathrm{~K}^{+}$ions; $1.50 \times 10^{-2} \mathrm{~mol}$ $\mathrm{Br}^{-} ; 9.02 \times 10^{21} \mathrm{Br}^{-}$ions 4.20 (a) $0.35 \mathrm{~mol} \mathrm{H}+\quad$ (b) $6.3 \times 10^{-3}$ $\mathrm{mol} \mathrm{H}{ }^{+}$(c) $0.22 \mathrm{~mol} \mathrm{H}^{+} \quad 4.24$ Spectator ions do not appear because they are not involved in the reaction and are present only to balance charge. 4.28 Assuming that the left beaker contains $\mathrm{AgNO}_{3}$ (because it has gray $\mathrm{Ag}^{+}$ion), the right must contain NaCl . Then, $\mathrm{NO}_{3}{ }^{-}$is blue, $\mathrm{Na}^{+}$is brown, and $\mathrm{Cl}^{-}$is green.
Molecular equation: $\mathrm{AgNO}_{3}(a q)+\mathrm{NaCl}(a q) \longrightarrow$

$$
\operatorname{AgCl}(s)+\mathrm{NaNO}_{3}(a q)
$$

Total ionic equation: $\mathrm{Ag}^{+}(a q)+\mathrm{NO}_{3}{ }^{-}(a q)+\mathrm{Na}^{+}(a q)+$ $\mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{AgCl}(s)+\mathrm{Na}^{+}(a q)+\mathrm{NO}_{3}{ }^{-}(a q)$
Net ionic equation: $\mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{AgCl}(s)$
4.29(a) Molecular: $\mathrm{Hg}_{2}\left(\mathrm{NO}_{3}\right)_{2}(a q)+2 \mathrm{KI}(a q) \longrightarrow$
$\mathrm{Hg}_{2} \mathrm{I}_{2}(s)+2 \mathrm{KNO}_{3}(a q)$
Total ionic: $\mathrm{Hg}_{2}{ }^{2+}(a q)+2 \mathrm{NO}_{3}{ }^{-}(a q)+2 \mathrm{~K}^{+}(a q)+$ $2 \mathrm{I}^{-}(a q) \longrightarrow \mathrm{Hg}_{2} \mathrm{I}_{2}(s)+2 \mathrm{~K}^{+}(a q)+2 \mathrm{NO}_{3}^{-}(a q)$
Net ionic: $\mathrm{Hg}_{2}{ }^{2+}(a q)+2 \mathrm{I}^{-}(a q) \longrightarrow \mathrm{Hg}_{2} \mathrm{I}_{2}(s)$
Spectator ions are $\mathrm{K}^{+}$and $\mathrm{NO}_{3}^{-}$.
(b) Molecular: $\mathrm{FeSO}_{4}(a q)+\mathrm{Sr}(\mathrm{OH})_{2}(a q) \longrightarrow$

$$
\mathrm{Fe}(\mathrm{OH})_{2}(s)+\mathrm{SrSO}_{4}(s)
$$

Total ionic: $\mathrm{Fe}^{2+}(a q)+\mathrm{SO}_{4}{ }^{2-}(a q)+\mathrm{Sr}^{2+}(a q)+$
$2 \mathrm{OH}^{-}(a q) \longrightarrow \mathrm{Fe}(\mathrm{OH})_{2}(s)+\mathrm{SrSO}_{4}(s)$
Net ionic: This is the same as the total ionic equation, because there are no spectator ions.
4.31(a) No precipitate will form. (b) A precipitate will form because silver ions, $\mathrm{Ag}^{+}$, and bromide ions, $\mathrm{Br}^{-}$, will combine to form a solid salt, silver bromide, AgBr . The ammonium and nitrate ions do not form a precipitate.
Molecular: $\mathrm{NH}_{4} \mathrm{Br}(a q)+\mathrm{AgNO}_{3}(a q) \longrightarrow$

$$
\mathrm{AgBr}(s)+\mathrm{NH}_{4} \mathrm{NO}_{3}(a q)
$$

Total ionic: $\mathrm{NH}_{4}{ }^{+}(a q)+\mathrm{Br}^{-}(a q)+\mathrm{Ag}^{+}(a q)+\mathrm{NO}_{3}^{-}(a q) \longrightarrow$ $\mathrm{AgBr}(s)+\mathrm{NH}_{4}{ }^{+}(a q)+\mathrm{NO}_{3}^{-}(a q)$
Net ionic: $\mathrm{Ag}^{+}(a q)+\mathrm{Br}^{-}(a q) \longrightarrow \mathrm{AgBr}(s)$
4.33(a) No precipitate will form.
(b) $\mathrm{BaSO}_{4}$ will precipitate.

$$
\text { Molecular: }\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}(a q)+\underset{\mathrm{BaSO}_{4}(s)+2 \mathrm{NH}_{4} \mathrm{Cl}(a q)}{\mathrm{BaCl}_{2}(a q) \longrightarrow}
$$

Total ionic: $2 \mathrm{NH}_{4}{ }^{+}(a q)+\mathrm{SO}_{4}{ }^{2-}(a q)+\mathrm{Ba}^{2+}(a q)+$

$$
2 \mathrm{Cl}^{-}(a q) \longrightarrow \mathrm{BaSO}_{4}(s)+2 \mathrm{NH}_{4}^{+}(a q)+\mathrm{Cl}^{-}(a q)
$$

Net ionic: $\mathrm{SO}_{4}{ }^{2-}(a q)+\mathrm{Ba}^{2+}(a q) \longrightarrow \mathrm{BaSO}_{4}(s)$
$4.350 .0354 \mathrm{M} \mathrm{Pb}^{2+} \quad 4.392 .206$ mass $\% \mathrm{Cl}^{-} \quad$ 4.45(a) Formation of a gas, $\mathrm{SO}_{2}(g)$, and of a nonelectrolyte (water) will cause the reaction to go to completion. (b) Formation of a precipitate $\mathrm{Ba}_{3}\left(\mathrm{PO}_{4}\right)_{2}(s)$, and of a nonelectrolyte (water) will cause the reaction to go to completion.
4.47(a) Molecular equation: $\mathrm{KOH}(a q)+\operatorname{HBr}(a q) \longrightarrow$

$$
\mathrm{KBr}(a q)+\mathrm{H}_{2} \mathrm{O}(l)
$$

Total ionic equation: $\mathrm{K}^{+}(a q)+\mathrm{OH}^{-}(a q)+\mathrm{H}^{+}(a q)+$ $\mathrm{Br}^{-}(a q) \longrightarrow \mathrm{K}^{+}(a q)+\mathrm{Br}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)$
Net ionic equation: $\mathrm{OH}^{-}(a q)+\mathrm{H}^{+}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)$
The spectator ions are $\mathrm{K}^{+}(a q)$ and $\mathrm{Br}^{-}(a q)$.
(b) Molecular equation: $\mathrm{NH}_{3}(a q)+\mathrm{HCl}(a q) \longrightarrow$
$\mathrm{NH}_{4} \mathrm{Cl}(a q)$
EnTotetionicequatien: $\mathrm{NH}_{3}(a q)+\mathrm{H}^{+}(a q)+\mathrm{Cl}^{-}(a q) \longrightarrow$ $\mathrm{NH}_{4}^{+}(a q)+\mathrm{Cl}^{-}(a q)$
$\mathrm{NH}_{3}$, a weak base, is written in the molecular (undis-
sociated) form. HCl , a strong acid, is written as dissociated ions. $\mathrm{NH}_{4} \mathrm{Cl}$ is a soluble compound, because all ammonium compounds are soluble.
Net ionic equation: $\mathrm{NH}_{3}(a q)+\mathrm{H}^{+}(a q) \longrightarrow \mathrm{NH}_{4}{ }^{+}(a q)$ $\mathrm{Cl}^{-}$is the only spectator ion.
4.49 Total ionic equation: $\mathrm{CaCO}_{3}(s)+2 \mathrm{H}^{+}(a q)+2 \mathrm{Cl}^{-}(a q) \longrightarrow$

$$
\mathrm{Ca}^{2+}(a q)+2 \mathrm{Cl}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g)
$$

Net ionic equation: $\mathrm{CaCO}_{3}(s)+2 \mathrm{H}^{+}(a q) \longrightarrow$
$\mathrm{Ca}^{2+}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g)$
$4.510 .05839 \mathrm{M} \mathrm{CH}_{3} \mathrm{COOH}$ 4.62(a) S has $\mathrm{O} . \mathrm{N}$. $=+6$ in
$\mathrm{SO}_{4}{ }^{2-}$ (i.e., $\mathrm{H}_{2} \mathrm{SO}_{4}$ ), and O.N. $=+4$ in $\mathrm{SO}_{2}$, so S has been reduced (and I ${ }^{-}$oxidized); $\mathrm{H}_{2} \mathrm{SO}_{4}$ acts as an oxidizing agent. (b) The oxidation numbers remain constant throughout; $\mathrm{H}_{2} \mathrm{SO}_{4}$ transfers a proton to $\mathrm{F}^{-}$to produce HF , so it acts as an acid.
4.64(a) +4

4.72 (a) $\mathrm{MnO}^{2}$
$4^{-}$is the oxidizing agent;
$\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$ is the reducing agent. (b) Cu is the reducing agent; $\mathrm{NO}_{3}{ }^{-}$is the oxidizing agent. 4.74(a) Oxidizing agent is $\mathrm{NO}_{3}{ }^{-}$; reducing agent is Sn . (b) Oxidizing agent is $\mathrm{MnO}_{4}{ }^{-}$; reducing agent is $\mathrm{Cl}^{-}$. 4.76 S is in Group $6 \mathrm{~A}(16)$, so its highest possible O.N. is +6 and its lowest possible O.N. is $6-8=-2$. (a) $\mathrm{S}=-2$. The S can only increase its O.N. (oxidize), so $\mathrm{S}^{2-}$ can function only as a reducing agent. (b) $\mathrm{S}=+6$. The S can only decrease its O.N. (reduce), so $\mathrm{SO}_{4}{ }^{2-}$ can function only as an oxidizing agent. (c) $S=+4$.

The S can increase or decrease its O.N. Therefore, $\mathrm{SO}_{2}$ can function as either an oxidizing or reducing agent.
4.78(a) $8 \mathrm{HNO}_{3}(a q)+\mathrm{K}_{2} \mathrm{CrO}_{4}(a q)+3 \mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{2}(a q) \longrightarrow$

$$
\approx \overbrace{\substack{\mathrm{H}_{2} \mathrm{O}(l) \text { (initial) } \\ \mathrm{H}_{2} \mathrm{O}(s)(\text { final }) \downarrow}} \Delta H=(-),(\text { exothermic) }
$$

6.26(a) $2 \mathrm{CH}_{3} \mathrm{OH}(l)+3 \mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(g)+$ heat

(b) ${ }_{2} \mathrm{~N}_{2}(g)+\mathrm{O}_{2}(g)+$ heat $\longrightarrow \mathrm{NO}_{2}(g)$

$$
\approx \xlongequal{\left.\frac{\mathrm{NO}_{2} \text { (final) }}{\frac{1}{2} \mathrm{~N}_{2}+\mathrm{O}_{2} \text { (initial) }} \right\rvert\,} \quad \Delta H=(+ \text { ), (endothermic) }
$$

6.28(a) This is a phase change from the solid phase to the gas phase. Heat is absorbed by the system so $q_{\text {sys }}$ is positive $(+)$.
(b) The volume of the system is expanding as more moles of gas are present after the phase change than were present before the phase change. So the system has done work of expansion, and $w$
is negative. Since $\Delta E_{\text {sys }}=q+w, q$ is positive, and $w$ is negative, the sign of $\Delta E_{\text {sys }}$ cannot be predicted. It will be positive if $q>w$ and negative if $q<w$. (c) $\Delta E_{\text {univ }}=0$. If the system loses energy, the surroundings gain an equal amount of energy. The sum of the energy of the system and the energy of the surroundings remains constant. $\quad 6.31$ To determine the specific heat capacity of a substance, you need its mass, the heat added (or lost), and the change in temperature. 6.33 Specific heat capacity is the quantity of heat required to raise one gram of a substance by one kelvin. Heat capacity is also the quantity of heat required for a one-kelvin temperature change, but it applies to an object instead of a specified amount of a substance. (a) Heat capacity, because the fixture is a combination of substances
(b) Specific heat capacity, because the copper wire is a pure substance (c) Specific heat capacity, because the water is a pure substance $\quad 6.356 .9 \times 10^{3} \mathrm{~J} \quad 6.37295^{\circ} \mathrm{C} \quad 6.3977 .5^{\circ} \mathrm{C} \quad 6.4145^{\circ} \mathrm{C}$ 6.43 $36.6^{\circ} \mathrm{C}$ 6.50 The reaction has a positive $\Delta H_{\mathrm{rxn}}$, because this reaction requires the input of energy to break the oxygenoxygen bond. $6.51 \Delta H$ is negative; it is opposite in sign and half of the value for the vaporization of 2 mol of $\mathrm{H}_{2} \mathrm{O}$.
$\begin{array}{llll}\text { 6.52(a) exothermic } & \text { (b) } 20.2 \mathrm{~kJ} & \text { (c) }-4.2 \times 10^{2} \mathrm{~kJ} & \text { (d) }-15.7 \mathrm{~kJ}\end{array}$

## Chapter 7

7.2(a) x-ray $<$ ultraviolet $<$ visible $<$ infrared $<$ microwave $<$ radio waves (b) radio $<$ microwave $<$ infrared $<$ visible $<$ ultraviolet $<$ x-ray (c) radio $<$ microwave $<$ infrared $<$ visible
<ultraviolet < x-ray $7.7316 \mathrm{~m} ; 3.16 \times 10^{11} \mathrm{~nm} ; 3.16 \times 10^{12} \AA$ $7.92 .5 \times 10^{-23} \mathrm{~J} \quad 7.11 \mathrm{~b}<\mathrm{c}<\mathrm{a} \quad 7.131 .3483 \times 10^{9} \mathrm{~nm}$; $1.3483 \times 10^{8} \AA \quad 7.16(a) 1.24 \times 10^{15} \mathrm{~s}^{-1} ; 8.21 \times 10^{-19} \mathrm{~J}$ (b) $1.4 \times 10^{15} \mathrm{~s}^{-1} ; 9.0 \times 10^{-19} \mathrm{~J} \quad 7.18$ Bohr's key assumption was that the electron in an atom does not radiate energy while in a stationary state, and it can move to a different orbit only by absorbing or emitting a photon whose energy is equal to the difference in energy between two states. These differences in energy correspond to the wavelengths in the known line spectra for the hydrogen atom. 7.20(a) absorption (b) emission (c) emission (d) absorption 7.22 Yes, the predicted line spectra are accurate. The energies could be predicted from
$E_{n}=\frac{-\left(Z^{2}\right)\left(2.18 \times 10^{-18} \mathrm{~J}\right)}{n^{2}}$, where $Z$ is the atomic number for the atom or ion. The energy levels for $\mathrm{Be}^{3+}$ will be greater by a factor of $16(Z=4)$ than those for the hydrogen atom. This means that the pattern of lines will be similar, but at different wavelengths. $7.23434 .17 \mathrm{~nm} \quad 7.251875 .6 \mathrm{~nm} \quad 7.27-2.76 \times 10^{5} \mathrm{~J} / \mathrm{mol}$ $7.29 \mathrm{~d}<\mathrm{a}<\mathrm{c}<\mathrm{b} \quad 7.31 n=4$ 7.37 Macroscopic objects do exhibit a wavelike motion, but the wavelength is too small for humans to perceive. $\quad 7.39$ (a) $7.10 \times 10^{-37} \mathrm{~m} \quad$ (b) $1 \times 10^{-35} \mathrm{~m}$ $7.412 .2 \times 10^{-26} \mathrm{~m} / \mathrm{s} \quad 7.433 .75 \times 10^{-36} \mathrm{~kg} \quad 7.47$ The total probability of finding the $1 s$ electron in any distance $r$ from the nucleus is greatest when the value of $r$ is $0.529 \AA$. 7.48(a) principal determinant of the electron's energy or distance from the nucleus (b) determines the shape of the orbital (c) determines the orientation of the orbital in three-dimensional space

## Chapter 8

8.1 Elements are listed in the periodic table in an ordered, systematic way that correlates with a periodicity of their chemical and physical properties. The theoretical basis for the table in terms of atomic number and electron configuration does not allow for a "new element" between Sn and Sb . 8.3(a) predicted atomic mass $=54.23 \mathrm{amu}$ (b) predicted melting point $=6.3^{\circ} \mathrm{C}$ 8.6 The quantum number $m_{s}$ relates to just the electron; all the others describe the orbital. 8.9 Shielding occurs when inner electrons protect, or shield, outer electrons from the full nuclear attraction. The effective nuclear charge is the nuclear charge an Felectron actualy experiences. As the number of inner electrons increases, the effective nuclear charge decreases. 8.11(a) 6 $\begin{array}{llll}\text { (b) } 10 & \text { (c) } 2 & \mathbf{8 . 1 3}(a) 6 & \text { (b) } 2\end{array}$ (c) $14 \quad \mathbf{8 . 1 3}$ Degenerate orbitals (those of identical energy) will be filled in such a way that the electron spins will have the same value.

8.18 Main-group elements from the same group have similar outer electron configurations, and the (old) group number equals the number of outer electrons. Outer electron configurations vary in a periodic manner within a period, with each succeeding element having an additional electron. 8.20 The maximum number of electrons in any energy level $n$ is $2 n^{2}$, so the $n=4$ energy level holds a maximum of $2\left(4^{2}\right)=32$ electrons.
8.21 (a) $n=5, l=0, m_{l}=0$, and $m_{s}=+\frac{1}{2} \quad$ (b) $n=3, l=1$,
$m_{l}=+1$, and $m_{s}=-\frac{1}{2} \quad$ (c) $n=5, l=0, m_{l}=0$, and

(b) $2 \mathrm{~A}(2) \quad$ (c) $6 \mathrm{~A}(16) \quad 9.26(\mathrm{a}) \mathrm{BaS}$; the charge on each ion is twice the charge on the ions in CsCl . (b) $\mathrm{LiCl} ; \mathrm{Li}^{+}$is smaller
than $\mathrm{Cs}^{+}$. 9.28(a) $\mathrm{BaS} ; \mathrm{Ba}^{2+}$ is larger than $\mathrm{Ca}^{2+}$. (b) NaF ; the charge on each ion is less than the charge on Mg and O . 9.30788 kJ ; the lattice energy for NaCl is less than that for LiF , because the $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions are larger than $\mathrm{Li}^{+}$and $\mathrm{F}^{-}$ions. $9.33-336 \mathrm{~kJ}$ 9.34 When two chlorine atoms are far apart, there is no interaction between them. As the atoms move closer together, the nucleus of each atom attracts the electrons of the other atom. The closer the atoms, the greater this attraction; however, the repulsions of the two nuclei and two electrons also increase at the same time. The final internuclear distance is the distance at which maximum attraction is achieved in spite of the repulsion. 9.35 The bond energy is the energy required to break the bond between H atoms and Cl atoms in one mole of HCl molecules in the gaseous state. Energy is needed to break bonds, so bond energy is always endothermic and $\Delta H_{\text {bond breaking }}^{\circ}$ is positive. The amount of energy needed to break the bond is released upon its formation, so $\Delta H_{\text {bond forming }}^{\circ}$ has the same magnitude as $\Delta H_{\text {bond breaking }}^{\circ}$ but is opposite in sign (always exothermic and negative). $\quad$ 9.39(a) $\mathrm{I}-\mathrm{I}<\mathrm{Br}-\mathrm{Br}<\mathrm{Cl}-\mathrm{Cl} \quad$ (b) $\mathrm{S}-\mathrm{Br}<$ $\mathrm{S}-\mathrm{Cl}<\mathrm{S}-\mathrm{H} \quad$ (c) $\mathrm{C}-\mathrm{N}<\mathrm{C}=\mathrm{N}<\mathrm{C} \equiv \mathrm{N} \quad$ 9.41(a) $\mathrm{C}-\mathrm{O}$ $<\mathrm{C}=\mathrm{O}$; the $\mathrm{C}=\mathrm{O}$ bond (bond order $=2$ ) is stronger than the $\mathrm{C}-\mathrm{O}$ bond (bond order $=1$ ). (b) $\mathrm{C}-\mathrm{H}<\mathrm{O}-\mathrm{H}$; O is smaller than C so the $\mathrm{O}-\mathrm{H}$ bond is shorter and stronger than the $\mathrm{C}-\mathrm{H}$ bond. 9.44 Less energy is required to break weak bonds. 9.46 Both are one-carbon molecules. Since methane contains fewer $\mathrm{C}=\mathrm{O}$ bonds, it will have the greater heat of reaction per mole for combustion. $\quad 9.48-168 \mathrm{~kJ} \quad 9.50-22 \mathrm{~kJ} \quad 9.51-59 \mathrm{~kJ}$ 9.52 Electronegativity increases from left to right and increases from bottom to top within a group. Fluorine and oxygen are the two most electronegative elements. Cesmpand fraciumpethe two least electronegative elements. 9.54 The $\mathrm{H}-\mathrm{O}$ bond in water is polar covalent. A nonpolar covalent bond occurs between two atoms with identical electronegativities. A polar covalent bond occurs when the atoms have differing electronegativities. Ionic bonds result from electron transfer between atoms.

much more negative than that for MgCl . $\quad 9.78$ (a) 406 nm (b) $2.93 \times 10^{-19} \mathrm{~J} \quad$ (c) $1.87 \times 10^{4} \mathrm{~m} / \mathrm{s} \quad 9.82 \mathrm{C}-\mathrm{Cl}: 3.53 \times 10^{-7} \mathrm{~m}$; bond in $\mathrm{O}_{2}: 2.40 \times 10^{-7} \mathrm{~m} \quad 9.83 \mathrm{XeF}_{2}: 132 \mathrm{~kJ} / \mathrm{mol} ; \mathrm{XeF}_{4}$ : $150 \mathrm{~kJ} / \mathrm{mol} ; \mathrm{XeF}_{6}: 146 \mathrm{~kJ} / \mathrm{mol} \quad$ 9.85(a) The presence of the very electronegative fluorine atoms bonded to one of the carbons makes the $\mathrm{C}-\mathrm{C}$ bond polar. This polar bond will tend to undergo heterolytic rather than homolytic cleavage. More energy is required to achieve heterolytic cleavage. (b) 1420 kJ
$9.88-13,286 \mathrm{~kJ} \quad 9.908 .70 \times 10^{14} \mathrm{~s}^{-1} ; 3.45 \times 10^{-7} \mathrm{~m}$, which is in the ultraviolet region of the electromagnetic spectrum.
9.92(a) $\mathrm{CH}_{3} \mathrm{OCH}_{3}(\mathrm{~g}):-326 \mathrm{~kJ} ; \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}(\mathrm{g}):-369 \mathrm{~kJ}$ (b) The formation of gaseous ethanol is more exothermic. (c) 43 kJ

## Chapter 10

10.1 He and H cannot serve as central atoms in a Lewis structure. Both can have no more than two valence electrons. Fluorine needs only one electron to complete its valence level, and it does not have $d$ orbitals available to expand its valence level. Thus, it can bond to only one other atom. 10.3 All the structures obey the octet rule except c and g .

(b)

10.15(a) $[: \mathrm{C} \equiv \mathrm{N}:]^{-}$formal charges: $\mathrm{C}=-1, \mathrm{~N}=0$

Y

Z

Yes, compound Y has a dipole moment.
10.61(a)

$\mathrm{H}-\ddot{\mathrm{N}}=\dot{\mathrm{N}}-\mathrm{H}$
$: N \equiv N$ :

Hydrazine
Diazene
Nitrogen
The single $\mathrm{N}-\mathrm{N}$ bond (bond order $=1$ ) is weaker and longer than the others. The triple bond (bond order $=3$ ) is stronger and shorter than the others. The double bond (bond order $=2$ ) has an intermediate strength and length.
(b) $\Delta H_{\mathrm{rxn}}^{\circ}=-367 \mathrm{~kJ}$

10.65(a) formal charges: $\mathrm{Al}=-1$, end $\mathrm{Cl}=0$, bridging $\mathrm{Cl}=$ $+1 ; \mathrm{I}=-1$, end $\mathrm{Cl}=0$, bridging $\mathrm{Cl}=+1 \quad$ (b) The iodine atoms are each $\mathrm{AX}_{4} \mathrm{E}_{2}$, and the shape around each is square planar. Placing these square planar portions adjacent gives a planar molecule.
10.70

(a) In propylene oxide, the C's have ideal angles of $109.5^{\circ}$.
(b) The C that is not part of the three-membered ring should have close to the ideal angle. The atoms in the ring form an equilateral triangle, so the angles around the two C's in the ring are reduced from the ideal $109.5^{\circ}$ to $60^{\circ}$.
10.72

The $\mathrm{Cl}-\mathrm{O}-\mathrm{Cl}$ bond angle is less than $109.5^{\circ}$ because of the lone pairs. $\quad 10.76$ (a) $-1267 \mathrm{~kJ} / \mathrm{mol}$ (b) $-1226 \mathrm{~kJ} / \mathrm{mol}$ (c) $-1234.8 \mathrm{~kJ} / \mathrm{mol}$. The two answers differ by less than $10 \mathrm{~kJ} / \mathrm{mol}$. This is very good agreement since average bond energies were used to calculate answers $a$ and $b$. (d) -37 kJ
10.79

$10.82 \mathrm{CH}_{4}:-409 \mathrm{~kJ} / \mathrm{mol} \mathrm{O}_{2} ; \mathrm{H}_{2} \mathrm{~S}:-398 \mathrm{~kJ} / \mathrm{mol} \mathrm{O}_{2}$
10.84(a) The O in the OH species only has 7 valence electrons, which is less than an octet, and 1 electron is unpaired. (b) 426 kJ (c) $508 \mathrm{~kJ} \quad$ 10.86(a) The F atoms will substitute at the axial positions first.
(b) $\mathrm{PF}_{5}$ and $\mathrm{PCl}_{3} \mathrm{~F}_{2}$
$10.88 \mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$ :

In $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}$, there are two shorter and stronger $\mathrm{C}=\mathrm{O}$ bonds and two longer and weaker $\mathrm{C}-\mathrm{O}$ bonds. In $\mathrm{HC}_{2} \mathrm{O}_{4}{ }^{-}$, the carbonoxygen bonds on the side retaining the H remain as one long, weak $\mathrm{C}-\mathrm{O}$ and one short, strong $\mathrm{C}=\mathrm{O}$. The carbon-oxygen bonds on the other side of the molecule have resonance forms with a bond order of 1.5 , so they are intermediate in length and strength. In $\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}$, all the carbon-oxygen bonds have a bond order of 1.5 . $10.9222 \mathrm{~kJ} \quad 10.93$ Trigonal planar molecules are nonpolar, so $\mathrm{AY}_{3}$ cannot be that shape. Trigonal pyramidal moleccles and T-shaped molecules are polar, so either could represent $\mathrm{AY}_{3} . \quad 10.98$ (a) $339 \mathrm{pm} \quad$ (b) 316 pm and 223 pm (c) 271 pm

(b) eight

## Chapter 12

12.1 In a solid, the energy of attraction of the particles is greater than their energy of motion; in a gas, it is less. Gases have high compressibility and the ability to flow, while solids have neither. 12.4(a) Because the intermolecular forces are only partially overcome when fusion occurs but need to be totally overcome in vaporization. (b) Because solids have greater intermolecular forces than liquids do. (c) $\Delta H_{\text {vap }}=-\Delta H_{\text {cond }} \quad 12.5$ (a) intermolecular (b) intermolecular (c) intramolecular
(d) intramolecular 12.7(a) condensation (b) fusion (c) vaporization 12.9 The gas molecules slow down as the gas is compressed. Therefore, much of the kinetic energy lost by the propane molecules is released to the surroundings. 12.13 At first, the vaporization of liquid molecules from the surface predominates, which increases the number of gas molecules and hence the vapor pressure. As more molecules entep hegasphase, DE gas molecules hit the surface of the liquid and "stick" more frequently, so the condensation rate increases. When the vaporization and condensation rates become equal, the vapor pressure becomes constant. 12.14 As intermolecular forces increase, (a) critical temperature increases, (b) boiling point increases, (c) vapor pressure decreases, and (d) heat of vaporization increases. 12.18 because the condensation of the vapor supplies an additional $40.7 \mathrm{~kJ} / \mathrm{mol} \quad 12.197 .67 \times 10^{3} \mathrm{~J}$ $12.210 .777 \mathrm{~atm} \quad 12.232 \times 10^{4} \mathrm{~J} / \mathrm{mol}$
12.25

Solid ethylene is more dense than liquid ethylene.
$12.2832 \mathrm{~atm} \quad 12.32 \mathrm{O}$ is smaller and more electronegative than Se ; so the electron density on O is greater, which attracts H more strongly. 12.34 All particles (atoms and molecules) exhibit dispersion forces, but the total force is weak for small molecules. Dipole-dipole forces between small polar molecules dominate
the dispersion forces. 12.37(a) hydrogen bonding (b) dispersion forces (c) dispersion forces 12.39(a) dipole-dipole forces
(b) dispersion forces
(c) hydrogen bonding
12.41(a)

(b)

12.43 (a) dispersion forces (b) hydrogen bonding (c) dispersion forces $12.45\left(\right.$ a) $\mathrm{I}^{-} \quad$ (b) $\mathrm{CH}_{2}=\mathrm{CH}_{2} \quad$ (c) $\mathrm{H}_{2} \mathrm{Se}$. In (a) and (c) the larger particle has the higher polarizability. In (b), the less tightly held $\pi$ electron clouds are more easily distorted.
$12.47\left(\right.$ a) $\mathrm{C}_{2} \mathrm{H}_{6}$; it is a smaller molecule exhibiting weaker dispersion forces than $\mathrm{C}_{4} \mathrm{H}_{10}$. (b) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{~F}$; it has no $\mathrm{H}-\mathrm{F}$ bonds, so it only exhibits dipole-dipole forces, which are weaker than the hydrogen bonds of $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$. (c) $\mathrm{PH}_{3}$; it has weaker intermolecular forces (dipole-dipole) than $\mathrm{NH}_{3}$ (hydrogen bonding). $\quad 12.49$ (a) HCl ; it has dipole-dipole forces, and there are stronger ionic bonds in LiCl . (b) $\mathrm{PH}_{3}$; it has dipole-dipole forces, and there is stronger hydrogen bonding in $\mathrm{NH}_{3}$. (c) Xe ; it exhibits weaker dispersion forces since its smaller size results in lower polarizability than the larger $\mathrm{I}_{2}$ molecules. $\quad 12.51$ (a) $\mathrm{C}_{4} \mathrm{H}_{8}$ (cyclobutane), because it is more compact than $\mathrm{C}_{4} \mathrm{H}_{10}$. (b) $\mathrm{PBr}_{3}$; the dipole-dipole forces in $\mathrm{PBr}_{3}$ are weaker than the ionic bonds in NaBr . (c) HBr ; the dipole-dipole forces in HBr are weaker than the hydrogen bonds in water. 12.53 As atomic size decreases and electronegativity increases, the electron density of an atomincreases. High electron density strengthens the attraction to an H atom on another molecule and makes its attached H atom more positive. Fluorine is the smallest of the three and the most electronegative, so the H bonds in hydrogen fluoride are the strongest. Oxygen is smaller and more electronegative than nitrogen, so H bonds in water are stronger than H bonds in ammonia. 12.57 The cohesive forces in water and mercury are stronger than the adhesive forces to the nonpolar wax on the floor. Weak adhesive forces result in spherical drops. The adhesive forces overcome the even weaker cohesive forces in the oil, and so the oil drop spreads out. 12.59 Surface tension is defined as the energy needed to increase the surface area by a given amount, so units of energy per area are appropriate. $12.61 \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}<\mathrm{HOCH}_{2} \mathrm{CH}_{2} \mathrm{OH}<$ $\mathrm{HOCH}_{2} \mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{2} \mathrm{OH}$. More hydrogen bonding means more attraction between molecules so more energy is needed to increase surface area. $\quad 12.63 \mathrm{HOCH}_{2} \mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{2} \mathrm{OH}>$ $\mathrm{HOCH}_{2} \mathrm{CH}_{2} \mathrm{OH}>\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$. More hydrogen bonding means more attraction between molecules, so they flow less easily. 12.68 Water is a good solvent for polar and ionic substances and a poor solvent for nonpolar substances. Water is a polar molecule and dissolves polar substances because their intermolecular forces are of similar strength. 12.69 A single water molecule can form four H bonds. The two hydrogen atoms each form one H bond to oxygen atoms on neighboring water molecules. The two lone pairs on the oxygen atom form H bonds with two hydrogen atoms on neighboring molecules. 12.72 Water exhibits strong capillary action, which allows it to be easily absorbed by the narrow spaces in the plant's roots and transported upward to the leaves. $\quad 12.78$ simple cubic 12.81 The energy gap is the energy difference between the highest filled energy level
(valence band) and the lowest unfilled energy level (conduction band). In conductors and superconductors, the energy gap is zero because the valence band overlaps the conduction band. In semiconductors, the energy gap is small. In insulators, the gap is large. 12.83 atomic mass and atomic radius 12.84(a) facecentered cubic (b) body-centered cubic (c) face-centered cubic 12.86(a) The change in unit cell is from a sodium chloride structure in CdO to a zinc blende structure in CdSe .
(b) Yes, the coordination number of Cd changes from 6 in CdO to 4 in CdSe. 12.88(a) Nickel forms a metallic solid since it is a metal whose atoms are held together by metallic bonds.
(b) Fluorine forms a molecular solid since the $\mathrm{F}_{2}$ molecules are held together by dispersion forces. (c) Methanol forms a molecular solid since the $\mathrm{CH}_{3} \mathrm{OH}$ molecules are held together by hydrogen bonds. (d) Tin forms a metallic solid since it is a metal whose atoms are held together by metallic bonds. (e) Silicon is in the same group as carbon, so it exhibits similar bonding properties. Since diamond and graphite are both network covalent solids, it makes sense that Si forms a network covalent solid as well.
(f) Xe is an atomic solid since its individual atoms are held together by dispersion forces. $\quad 12.90$ four 12.92 (a) four $\mathrm{Se}^{2-}$ ions, four $\mathrm{Zn}^{2+}$ ions (b) $577.48 \mathrm{amu} \quad$ (c) $1.77 \times 10^{-22} \mathrm{~cm}^{3}$

## Chapter 13

13.2 When a salt such as NaCl dissolves, ion-dipole forces cause the ions to separate, and many water molecules cluster around each ion in hydration shells. 13.4 Sodium stearate would be a more effective soap because the hydrocarbon chain in the stearate ion is longer than that in the acetate ion. The longer chain allows for more dispersion forces with grease molecules. $13.7 \mathrm{KNO}_{3}$ is an ionic compound and is therefore more soluble in water. 13.9(a) ion-dipole forces (b) hydrogen bonding
(c) dipole-induced dipole forces
13.11(a) hydrogen bonding
(b) dipole-induced dipole forces
(c) dispersion forces
13.13(a) $\mathrm{HCl}(g)$, because the molecular interactions (dipoledipole forces) in ether are like those in HCl but not like the ionic bonding in NaCl . (b) $\mathrm{CH}_{3} \mathrm{CHO}(l)$, because the molecular interactions with ether (dipole-dipole) can replace those between ${ }_{5} \mathrm{CH}_{3} \mathrm{CHO}_{\text {but }}$ not the H bonds in water. (c) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{MgBr}(s)$, because the molecular interactions (dispersion forces) are greater than between ether and the ions in $\mathrm{MgBr}_{2}$. 13.16 Gluconic acid is soluble in water due to extensive hydrogen bonding by the - OH groups attached to five of its carbons. The dispersion forces in the nonpolar tail of caproic acid are more similar to the dispersion forces in hexane; thus, caproic acid is soluble in hexane. 13.18 The nitrogen-containing bases form H bonds to their complementary bases. The flat, N -containing bases stack above each other, which allows extensive dispersion forces. The exterior negatively charged sugar-phosphate chains form iondipole and H bonds with water molecules in the aqueous surroundings, which also stabilizes the structure. 13.20 Dispersion forces are present between the nonpolar tails of the lipid molecules within the bilayer. Polar heads form H bonds and iondipole forces with the aqueous surroundings. 13.25 The energy change needed to separate the solvent $\left(\Delta H_{\text {solvent }}\right)$ and that needed to mix the solvent and solute ( $\Delta H_{\text {mix }}$ ) combine to obtain
$\Delta H_{\text {solution }}$ 13.29 Very soluble because a decrease in enthalpy and an increase in entropy both favor the formation of a solution. 13.30

13.32(a) The volume of $\mathrm{Na}^{+}$is smaller, so it has the greater charge density. (b) $\mathrm{Sr}^{2+}$ has a larger ionic charge and a smaller volume, so it has the greater charge density. (c) $\mathrm{Na}^{+}$is smaller than $\mathrm{Cl}^{-}$, so it has the greater charge density. (d) $\mathrm{O}^{2-}$ has a larger ionic charge with a similar ion volume, so it has the greater charge density. (e) $\mathrm{OH}^{-}$has a smaller volume than $\mathrm{SH}^{-}$, so it has the greater charge density. (f) $\mathrm{Mg}^{2+}$ has a smaller volume, so it has the greater charge density. (g) $\mathrm{Mg}^{2+}$ has both a smaller volume and a larger ionic charge, so it has the greater charge density. (h) $\mathrm{CO}_{3}{ }^{2-}$ has both a smaller volume and a larger ionic charge, so it has the greater charge density.
13.34(a) $\mathrm{Na}^{+}$
(b) $\mathrm{Sr}^{2+}$
(c) $\mathrm{Na}^{+}$
(d) $\mathrm{O}^{2-}$
(e) $\mathrm{OH}^{-}$
(f) $\mathrm{Mg}^{2+}$
(g) $\mathrm{Mg}^{2+}$
(h) $\mathrm{CO}_{3}{ }^{2-}$
13.36(a) $-704 \mathrm{~kJ} / \mathrm{mol}$
(b) The $\mathrm{K}^{+}$ion contributes more because it is smaller and, therefore, has a greater charge density. 13.38(a) increases (b) decreases (c) increases 13.41 Add a pinch of the solid solute to each solution. Addition of a "seed" crystal of solute to a supersaturated solution causes the excess solute to crystallize immediately, leaving behind a saturated solution. The solution in which the added solid solute dissolves is the unsaturated solution. The solution in which the added solid solute remains undissolved is the saturated solution. 13.44 (a) increase (b) decrease $\quad 13.46$ (a) $0.102 \mathrm{~g} \mathrm{O}_{2} \quad$ (b) $0.0214 \mathrm{~g} \mathrm{O}_{2}$ $13.490 .20 \mathrm{~mol} / \mathrm{L} \quad 13.52$ (a) molarity and $\% \mathrm{w} / \mathrm{v}$ or $\% \mathrm{v} / \mathrm{v}$ (b) parts-by-mass (\% w/w) (c) molality 13.54 With just this information, you can convert between molality and molarity, but you need to know the molar mass of the solvent to convert to mole fraction. $\quad 13.56$ (a) $0.944 M \mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11} \quad$ (b) $0.167 M \mathrm{LiNO}_{3}$ 13.58(a) 0.0749 M NaOH (b) $0.36 \mathrm{M} \mathrm{HNO}_{3} \quad$ 13.60(a) Add 4.25 g $\mathrm{KH}_{2} \mathrm{PO}_{4}$ to enough water to make 365 mL of aquep efelution PD (b) Add 125 mL of 1.25 M NaOH to enough water to make 465 mL of solution. $\quad 13.62$ (a) Weigh out 48.0 g KBr , dissolve it in about 1 L distilled water, and then dilute to 1.40 L with distilled water. (b) Measure 82.7 mL of the $0.264 M$ solution and add distilled water to make a total of $255 \mathrm{~mL} . \quad$ 13.64(a) 0.896 m glycine (b) 1.21 m glycerol $\quad 13.664 .48 \mathrm{~m}_{6} \mathrm{H}_{6} \quad$ 13.68(a) Add $2.39 \mathrm{~g} \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}$ to $308 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$. (b) Add 0.0508 kg of $52.0 \%$ $\mathrm{HNO}_{3}$ by mass to $1.15 \mathrm{~kg} \mathrm{H}_{2} \mathrm{O}$ to make 1.20 kg of $2.20 \% \mathrm{HNO}_{3}$ by mass. 13.70 (a) 0.29 (b) 58 mass $\%$ (c) $23 m \mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}$ 13.7242 .6 g CsBr ; mole fraction $=7.82 \times 10^{-3} ; 8.51 \%$ by mass $13.745 .11 \mathrm{~m} \mathrm{NH}_{3} ; 4.53 \mathrm{M} \mathrm{NH}_{3}$; mole fraction $=0.0843$
13.76 $2.5 \mathrm{ppm} \mathrm{Ca}{ }^{2+}, 0.56 \mathrm{ppm} \mathrm{Mg}{ }^{2+} \quad 13.80$ It creates a "strong" current. A strong electrolyte dissociates completely in solution. 13.82 The boiling point is higher and the freezing point is lower for the solution compared to the solvent. 13.85 A dilute solution of an electrolyte behaves more ideally than a concentrated one. With increasing concentration, the effective concentration deviates from the molar concentration because of ionic attractions. Thus, 0.050 m NaF has a boiling point closer to its predicted value. 13.88(a) strong electrolyte (b) strong electrolyte (c) nonelectrolyte (d) weak electrolyte 13.90 (a) 0.6 mol of $\begin{array}{llll}\text { solute particles } & \text { (b) } 0.13 \mathrm{~mol} & \text { (c) } 2 \times 10^{-4} \mathrm{~mol} & \text { (d) } 0.06 \mathrm{~mol}\end{array}$ 13.92(a) $\mathrm{CH}_{3} \mathrm{OH}$ in $\mathrm{H}_{2} \mathrm{O} \quad$ (b) $\mathrm{H}_{2} \mathrm{O}$ in $\mathrm{CH}_{3} \mathrm{OH}$ solution 13.94(a) $\Pi_{\text {II }}<\Pi_{\text {I }}<\Pi_{\text {III }}$
(b) $b p_{\text {II }}<b p_{\text {I }}<b p_{\text {III }}$
(c) $\mathrm{fp}_{\text {III }}<\mathrm{fp}_{\text {I }}<\mathrm{fp}_{\text {II }}$ (d) $\mathrm{vp}_{\text {III }}<\mathrm{vp}_{\text {I }}<\mathrm{vp}_{\text {II }} \quad 13.9623 .4$ torr $13.98-0.467^{\circ} \mathrm{C} \quad 13.100 \quad 79.5^{\circ} \mathrm{C} \quad 13.1021 .18 \times 10^{4} \mathrm{~g} \mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{2}$ 13.104(a) NaCl : $0.173 m$ and $i=1.84$ (b) $\mathrm{CH}_{3} \mathrm{COOH}: 0.0837 m$ and $i=1.02 \quad 13.1060 .249 \mathrm{~atm} \quad 13.108209$ torr for $\mathrm{CH}_{2} \mathrm{Cl}_{2}$; 48.1 torr for $\mathrm{CCl}_{4}$ 13.109 The fluid inside a bacterial cell is both a solution and a colloid. It is a solution of ions and small
molecules and a colloid of large molecules (proteins and nucleic acids). 13.113 Soap micelles have nonpolar tails pointed inward and anionic heads pointed outward. The charges on the heads of one micelle repel those on the heads of a neighboring micelle because the charges are the same. This repulsion between micelles keeps them from coagulating. Soap is more effective in freshwater than in seawater because the divalent cations in seawater combine with the anionic heads to form a precipitate.
$13.1173 .4 \times 10^{9} \mathrm{~L} \quad 13.1210 .0^{\circ} \mathrm{C}: 4.53 \times 10^{-4} \mathrm{M} \mathrm{O}_{2}$; $20.0^{\circ} \mathrm{C}: 2.83 \times 10^{-4} \mathrm{M} \mathrm{O}_{2} ; 40.0^{\circ} \mathrm{C}: 2.00 \times 10^{-4} \mathrm{M} \mathrm{O}_{2}$
13.123(a) $89.9 \mathrm{~g} / \mathrm{mol} \quad$ (b) $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{O} ; \mathrm{C}_{4} \mathrm{H}_{10} \mathrm{O}_{2}$
(c) Forms H bonds:

Does not form H bonds:

13.127 (a) $9.45 \mathrm{~g} \mathrm{NaF} \quad$ (b) $0.0017 \mathrm{~g} \mathrm{~F}^{-} \quad$ 13.131(a) $68 \mathrm{~g} / \mathrm{mol}$ (b) $2.1 \times 10^{2} \mathrm{~g} / \mathrm{mol} \quad$ (c) The molar mass of $\mathrm{CaN}_{2} \mathrm{O}_{6}$ is $164.10 \mathrm{~g} / \mathrm{mol}$. This value is less than the $2.1 \times 10^{2} \mathrm{~g} / \mathrm{mol}$ calculated when the compound is assumed to be a strong electrolyte and is greater than the $68 \mathrm{~g} / \mathrm{mol}$ calculated when the compound is assumed to be a nonelectrolyte. Thus, the compound forms a nonideal solution because the ions interact but do not dissociate completely in solution. (d) $i=2.4 \quad 13.135$ (a) $1.82 \times 10^{4} \mathrm{~g} / \mathrm{mol}$ (b) $3.4 \times 4 \emptyset^{\text {aq }}$ C $13.1369 .4 \times 10^{5} \mathrm{ng} / \mathrm{L} \quad 13.140$ (a) 0.02
(b) $5 \times 10^{-3} \mathrm{~atm} \cdot \mathrm{~L} / \mathrm{mol}$
(c) $6.3 \times 10^{-6} \mathrm{~atm} \cdot \mathrm{~m}^{3} / \mathrm{mol}$
13.142 Weigh $3.11 \mathrm{~g} \mathrm{NaHCO}_{3}$ and dissolve in 247 g water. 13.146 $M=m$ (kg solvent/L solution) $=m \times d_{\text {solution. }}$. Thus, for very dilute solutions molality $\times$ density $=$ molarity. In an aqueous solution, the liters of solution have approximately the same value as the kg of solvent because the density of water is close to $1 \mathrm{~kg} / \mathrm{L}$, so $m=M . \quad 13.148$ (a) $2.5 \times 10^{-3} M \mathrm{SO}_{2} \quad$ (b) The base reacts with the sulfur dioxide to produce calcium sulfite. The reaction of sulfur dioxide makes "room" for more sulfur dioxide to dissolve. 13.153 Mass percents: iodine in chloroform: $2.6 \% \mathrm{I}_{2}$; iodine in carbon tetrachloride: $2.4 \% \mathrm{I}_{2}$; iodine in carbon disulfide: $14 \% \mathrm{I}_{2}$; Mole fractions: iodine in chloroform: 0.012 ; iodine in carbon tetrachloride: 0.015 ; iodine in carbon disulfide: 0.046 ; Molality: iodine in chloroform: $0.11 \mathrm{~m}_{2}$; iodine in carbon tetrachloride: $0.098 \mathrm{~m}_{2}$; iodine in carbon disulfide: $0.63 \mathrm{~m}_{2}$ 13.157(a) $0.0212 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{atm} \quad$ (b) $8.90 \mathrm{ppm} \quad$ (c) $\mathrm{k}_{\mathrm{H}}: \mathrm{C}_{6} \mathrm{~F}_{14}>$ $\mathrm{C}_{6} \mathrm{H}_{14}>$ ethanol $>$ water. To dissolve oxygen in a solvent, the solvent molecules must be moved apart to make room for the gas. The stronger the intermolecular forces in the solvent, the more difficult it is to separate solvent particles and the lower the solubility of the gas. Both $\mathrm{C}_{6} \mathrm{~F}_{14}$ and $\mathrm{C}_{6} \mathrm{H}_{14}$ have weak dispersion forces, with $\mathrm{C}_{6} \mathrm{~F}_{14}$ having the weaker forces due to the electronegative fluorine atoms repelling each other. Both ethanol and water are held together by strong hydrogen bonds with those bonds being stronger in water, as the boiling point indicates. 13.159(a) Yes, the phases of water can still coexist at some temperature and can therefore establish equilibrium. (b) The triple point would occur at a lower pressure and lower temperature because the dissolved air would lower the vapor pressure of the
solvent. (c) Yes, this is possible because the gas-solid phase boundary exists below the new triple point. (d) No; at both temperatures, the presence of the solute lowers the vapor pressure of the liquid. $\quad 13.161$ (a) $2.8 \times 10^{-4} \mathrm{~g} / \mathrm{mL} \quad$ (b) 81 mL

## Chapter 14

14.2(a) $Z_{\text {eff }}$, the effective nuclear charge, increases significantly across a period and decreases slightly down a group. (b) Moving across a period, atomic size decreases, $\mathrm{IE}_{1}$ increases, and EN increases, all because of the increased $Z_{\text {eff. }} \quad$ 14.3(a) Polarity is the molecular property that is responsible for the difference in boiling points between iodine monochloride (polar) and bromine (nonpolar). It arises from different EN values of the bonded atoms. (b) The boiling point of polar ICl is higher than the boiling point of $\mathrm{Br}_{2}$. 14.7 The leftmost element in a period is an alkali metal [except for hydrogen in Group 1A(1)]. As we move to the right, the bonding to the other atom changes from metallic to polar covalent to ionic. The IE, EA, and EN of the two atoms become increasingly different, causing changes in the character of the bond. 14.9 The elements on the left side in Period 3 form cations. The loss of electrons leads to an ion smaller than the atom. The elements on the right side form anions. The gain of electrons leads to an ion larger than the atom. 14.11(a) The greater the electronegativity of the element, the more covalent the bonding is in its oxide. (b) The more electronegative the element, the more acidic the oxide is. 14.14 In general, network solids have very high melting and boiling points and are very hard, while molecular solids have low melting and boiling points and are soft. The properties of network solids reflect the necessity of breaking chemical bonds throughipthe ¢ibstances, DE whereas the properties of molecular solids reflect the weaker forces between individual molecules. 14.15 (a) $\mathrm{Mg}<\mathrm{Sr}<\mathrm{Ba}$
(b) $\mathrm{Na}<\mathrm{Al}<\mathrm{P}$
(c) $\mathrm{Se}<\mathrm{Br}<\mathrm{Cl}$
(d) $\mathrm{Ga}<\mathrm{Sn}<\mathrm{Bi}$

14.23(a) $\mathrm{Na}^{+}<\mathrm{F}^{-}<\mathrm{O}^{2-}$
(b) $\mathrm{Cl}^{-}<\mathrm{S}^{2-}<\mathrm{P}^{3-}$
$14.25 \mathrm{O}<\mathrm{O}^{-}<\mathrm{O}^{2-}$
14.27(a) $\mathrm{CaO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$
$\mathrm{Ca}(\mathrm{OH})_{2}(s) \rightleftharpoons \mathrm{Ca}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)$ (more basic)
$\mathrm{SO}_{3}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(a q) \longrightarrow \mathrm{H}^{+}(a q)+\mathrm{HSO}_{4}^{-}(a q)$
(b) BaO
(c) $\mathrm{CO}_{2} \quad$ (d) $\mathrm{K}_{2} \mathrm{O}$
14.29(a) LiCl
(b) $\mathrm{PCl}_{3}$
(c) $\mathrm{NCl}_{3}$ 14.31(a) $\mathrm{Ar}<\mathrm{Na}<\mathrm{Si} \quad$ (b) $\mathrm{Cs}<\mathrm{Rb}<\mathrm{Li} \quad$ 14.33 The outermost electron is attracted by a smaller effective nuclear charge in Li because of shielding by the inner electrons, and it is farther from the nucleus in Li. Both of these factors lead to a lower ionization energy.
14.35(a) $\mathrm{NH}_{3}$ will hydrogen bond.

(b) $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ will hydrogen bond.

14.37(a) $2 \mathrm{Al}(s)+6 \mathrm{HCl}(a q) \longrightarrow 2 \mathrm{AlCl}_{3}(a q)+3 \mathrm{H}_{2}(g)$
(b) $\mathrm{LiH}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{LiOH}(a q)+\mathrm{H}_{2}(g)$
14.39(a) $\mathrm{NaBH}_{4}$ : +1 for $\mathrm{Na},+3$ for $\mathrm{B},-1$ for H $\mathrm{Al}\left(\mathrm{BH}_{4}\right)_{3}:+3$ for $\mathrm{Al},+3$ for $\mathrm{B},-1$ for H $\mathrm{LiAlH}_{4}:+1$ for $\mathrm{Li},+3$ for $\mathrm{Al},-1$ for H
(b) tetrahedral

14.42 For Groups $1 \mathrm{~A}(1)$ to $4 \mathrm{~A}(14)$, the number of covalent bonds equals the (old) group number. For Groups $5 \mathrm{~A}(15)$ to $7 \mathrm{~A}(17)$, it equals 8 minus the (old) group number. There are exceptions in Period 3 to Period 6 because it is possible for the $3 \mathrm{~A}(13)$ to 7A(17) elements to use $d$ orbitals and form more bonds.
14.45(a) Group $3 \mathrm{~A}(13)$ or $3 \mathrm{~B}(3)$ (b) If E is in Group $3 \mathrm{~B}(3)$, the oxide and fluoride will be more ionic. 14.48(a) reducing agent (b) Alkali metals have relatively low ionization energies, which means they easily lose the outermost electron.
(c) $2 \mathrm{Na}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 2 \mathrm{Na}^{+}(a q)+2 \mathrm{OH}^{-}(a q)+\mathrm{H}_{2}(g)$
$2 \mathrm{Na}(s)+\mathrm{Cl}_{2}(g) \longrightarrow 2 \mathrm{NaCl}(s)$
14.50 Density and ionic size increase down a group; the other three properties decrease down a group.
$14.522 \mathrm{Na}(s)+\mathrm{O}_{2}(g) \longrightarrow \mathrm{Na}_{2} \mathrm{O}_{2}(s)$
$14.54 \mathrm{~K}_{2} \mathrm{CO}_{3}(s)+2 \mathrm{HI}(a q) \longrightarrow 2 \mathrm{KI}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(g)$
14.58 Group $2 \mathrm{~A}(2)$ metals have an additional bonding electron to increase the strength of metallic bonding, which leads to higher melting points, higher boiling points, greater hardness, and greater density.
14.59(a) $\mathrm{CaO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(s)$
(b) $2 \mathrm{Ca}(\mathrm{s})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{CaO}(\mathrm{s})$
14.62(a) $\mathrm{BeO}(s)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$ no reaction
(b) $\mathrm{BeCl}_{2}(l)+2 \mathrm{Cl}^{-}$(solvated) $\longrightarrow \mathrm{BeCl}_{4}{ }^{2-}$ (solvated).

FBe behaves like other Group $2 \mathrm{~A}(2)$ elements in reaction (b).
14.65 The electron removed from Group 2A(2) atoms occupies the outer $s$ orbital, whereas in Group 3A(13) atoms, the electron occupies the outer $p$ orbital. For example, the electron configuration for Be is $1 s^{2} 2 s^{2}$ and for B it is $1 s^{2} 2 s^{2} 2 p^{1}$. It is easier to remove the $p$ electron of B than an $s$ electron of Be , because the energy of a $p$ orbital is higher than that of the $s$ orbital of the same level. Even though atomic size decreases because of increasing $Z_{\text {eff }}$, IE decreases from $2 \mathrm{~A}(2)$ to $3 \mathrm{~A}(13)$.
14.66(a) Most atoms form stable compounds when they complete their outer shell (octet). Some compounds of Group 3A(13) elements, like boron, have only six electrons around the central atom. Having fewer than eight electrons is called electron deficiency.
(b) $\mathrm{BF}_{3}(g)+\mathrm{NH}_{3}(g) \longrightarrow \mathrm{F}_{3} \mathrm{~B}-\mathrm{NH}_{3}(g)$
$\mathrm{B}(\mathrm{OH})_{3}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{B}(\mathrm{OH})_{4}{ }^{-}(a q)$
$14.68 \mathrm{In}_{2} \mathrm{O}_{3}<\mathrm{Ga}_{2} \mathrm{O}_{3}<\mathrm{Al}_{2} \mathrm{O}_{3}$ 14.70 Apparent O.N., +3 ; actual
O.N., +1 . $[: \ddot{\mathrm{I}}-\ddot{\mathrm{I}}-\ddot{\mathrm{I}} \cdot]^{-}$The anion $\mathrm{I}_{3}{ }^{-}$has the general formula
$\mathrm{AX}_{2} \mathrm{E}_{3}$ and bond angles of $180^{\circ}$. $\left(\mathrm{Tl}^{3+}\right)\left(\mathrm{I}^{-}\right)_{3}$ does not exist because of the low strength of the $\mathrm{Tl}-\mathrm{I}$ bond.
14.75(a) $\mathrm{B}_{2} \mathrm{O}_{3}(s)+2 \mathrm{NH}_{3}(g) \longrightarrow 2 \mathrm{BN}(s)+3 \mathrm{H}_{2} \mathrm{O}(g)$
(b) $1.30 \times 10^{2} \mathrm{~kJ}$ (c) 5.3 kg borax $\quad 14.76$ Basicity in water is greater for the oxide of a metal. Tin(IV) oxide is more basic in water than carbon dioxide because tin has more metallic character than carbon. 14.78(a) Ionization energy generally decreases down a group. (b) The deviations (increases) from the expected trend are due to the presence of the first transition series between Si and Ge and of the lanthanides between Sn and Pb . (c) Group 3A(13) 14.81 Atomic size increases down a group. As atomic size increases, ionization energy decreases and so it is easier to form a positive ion. An atom that is easier to ionize exhibits greater metallic character.

(b)

The nitronium ion $\left(\mathrm{NO}_{2}{ }^{+}\right)$has a linear shape because the central N atom has two surrounding electron groups, which achieve maximum repulsion at 180 . The nitrite ion $\left(\mathrm{NO}_{2}{ }^{-}\right)$bond angle is more compressed than the nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$ bond angle because the lone pair of electrons takes up more space than the lone electron. $14.1742 .29 \times 10^{4} \mathrm{~g} \mathrm{UF}_{6} \quad 14.179 \mathrm{O}^{+}, \mathrm{O}^{-}$, and $\mathrm{O}^{2+} \quad 14.180$ (a) 39.96 mass $\%$ in $\mathrm{CuHAsO}_{3}$; As, 62.42 mass $\%$ in $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{As} \quad$ (b) $0.35 \mathrm{~g} \mathrm{CuHAsO}_{3}$

## Chapter 15

15.3(a) Carbon's electronegativity is midway between the most metallic and nonmetallic elements of Period 2. To attain a filled outer shell, carbon forms covalent bonds to other atoms in molecules, network covalent solids, and polyatomic ions. (b) Since carbon has four valence shell electrons, it forms four covalent bonds to attain an octet. (c) To reach the He electron configuration, a carbon atom must lose four electrons, requiring too much energy to form the $\mathrm{C}^{4+}$ cation. To reach the Ne electron configuration, the carbon atom must gain four electrons, also requiring too much energy to form the $\mathrm{C}^{4-}$ anion. (d) Carbon is able to bond to itself extensively because its snall size alloys fopglosey approach and great orbital overlap. The extensive orbital overlap results in a strong, stable bond. (e) The $\mathrm{C}-\mathrm{C}$ bond is short enough to allow sideways overlap of unhybridized $p$ orbitals of neighboring C atoms. The sideways overlap of $p$ orbitals results in the $\pi$ bonds that are part of double and triple bonds.
15.4(a) C H, O, N, P, S, and halogens (b) Heteroatoms are atoms of any element other than carbon and hydrogen. (c) More electronegative than $\mathrm{C}: \mathrm{N}, \mathrm{O}, \mathrm{F}, \mathrm{Cl}$, and Br ; less electronegative than C: H and P. Sulfur and iodine have the same electronegativity as carbon. (d) Since carbon can bond to a wide variety of heteroatoms and to carbon atoms, it can form many different compounds. 15.7 The $\mathrm{C}-\mathrm{H}$ and $\mathrm{C}-\mathrm{C}$ bonds are unreactive because electron density is shared equally between the two atoms. The $\mathrm{C}-\mathrm{I}$ bond is somewhat reactive because it is long and weak. The $\mathrm{C}=\mathrm{O}$ bond is reactive because oxygen is more electronegative than carbon and the electron-rich $\pi$ bond makes it attract electron-poor atoms. The $\mathrm{C}-\mathrm{Li}$ bond is also reactive because the bond polarity results in an electron-rich region around carbon and an electron-poor region around lithium. 15.8(a) An alkane and a cycloalkane are organic compounds that consist of carbon and hydrogen and have only single bonds. A cycloalkane has a ring of carbon atoms. An alkene is a hydrocarbon with at least one double bond. An alkyne is a hydrocarbon with at least one triple bond. (b) alkane $=\mathrm{C}_{n} \mathrm{H}_{2 n+2}$, cycloalkane $=\mathrm{C}_{n} \mathrm{H}_{2 n}$, alkene $=\mathrm{C}_{n} \mathrm{H}_{2 n}$, alkyne $=\mathrm{C}_{n} \mathrm{H}_{2 n-2}$ (c) Alkanes and cycloalkanes are saturated hydrocarbons.

## Chapter 16

16.2 Reaction rate is proportional to concentration. An increase in pressure will increase the concentration, resulting in an increased reaction rate. 16.3 The addition of water will dilute the concentrations of all dissolved solutes, and the rate of the reaction will decrease. 16.5 An increase in temperature affects the rate of a reaction by increasing the number of collisions between particles, but more importantly, the energy of collisions increases. Both these factors increase the rate of reaction.
16.8(a) For most reactions, the rate changes as the reaction progresses. The instantaneous rate is the rate at one point, or instant, during the reaction. The average rate is the average of the instantaneous rates over a period of time. On a graph of reactant concentration vs. time of reaction, the instantaneous rate is the slope of the tangent to the curve at any one point. The average rate is the slope of the line connecting two points on the curve. The closer together the two points (the shorter the time interval),
the more closely the average rate agrees with the instantaneous rate. (b) The initial rate is the instantaneous rate at the point on the graph where $t=0$, that is, when reactants are mixed.

16.12(a) rate $=-\left(\frac{1}{2}\right) \frac{\Delta \mathrm{AX}_{2}}{\Delta t}$

$$
=-\left(\frac{1}{2}\right) \frac{(0.0088 M-0.0500 M)}{(20.0 \mathrm{~s}-0 \mathrm{~s})}
$$

$$
=0.0010 \mathrm{M} / \mathrm{s}
$$

(b)

The initial rate is higher than the average rate because the rate will decrease as reactant concentration decreases.
16.14 rate $=-\frac{1}{2} \frac{\Delta[\mathrm{~A}]}{\Delta t}=\frac{\Delta[\mathrm{B}]}{\Delta t}=\frac{\Delta[\mathrm{C}]}{\Delta t} ; 4 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$
16.16 rate $=-\frac{\Delta[\mathrm{A}]}{\Delta t}=-\frac{1}{2} \frac{\Delta[\mathrm{~B}]}{\Delta t}=\frac{\Delta[\mathrm{C}]}{\Delta t} ; 0.2 \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$
$16.182 \mathrm{~N}_{2} \mathrm{O}_{5}(g) \longrightarrow 4 \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)$
16.21 rate $=-\frac{\Delta\left[\mathrm{N}_{2}\right]}{\Delta t}=-\frac{1}{3} \frac{\Delta\left[\mathrm{H}_{2}\right]}{\Delta t}=\frac{1}{2} \frac{\Delta\left[\mathrm{NH}_{3}\right]}{\Delta t}$
16.22(a) rate $=-\frac{1}{3} \frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}=\frac{1}{2} \frac{\left[\Delta \mathrm{O}_{3}\right]}{\Delta t} \quad$ (b) $1.45 \times 10^{-5} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$
16.23 (a) $k$ is the rate constant, the proportionality constant in the rate law; it is reaction and temperature specific. (b) $m$ represents the order of the reaction with respect to [A], and $n$ represents the order of the reaction with respect to $[\mathrm{B}]$. The order of a reactant does not necessarily equal its stoichiometric coefficient in the balanced equation. (c) $\mathrm{L}^{2} / \mathrm{mol}^{2} \cdot \min \quad 16.25$ (a) Rate doubles. (b) Rate decreases by a factor of four. (c) Rate increases by a factor of nine. $\quad 16.26$ first order in $\mathrm{BrO}_{3}{ }^{-}$; first order in $\mathrm{Br}^{-}$; second order in $\mathrm{H}^{+}$; fourth order overall
16.28(a) Rate doubles.
(b) Rate is halved. (c) The rate increases by a factor of $16 . \quad 16.30$ second order in $\mathrm{NO}_{2}$; first order in Cl ; third order overall 16.32(a) Rate increases by a factor of 9 . (b) Rate increases by a factor of 8 . (c) Rate is halved. 16.34(a) second order in A; first order in B (b) rate $=k[\mathrm{~A}]^{2}[\mathrm{~B}]$
(c) $5.00 \times 10^{3} \mathrm{~L}^{2} / \mathrm{mol}^{2} \cdot \mathrm{~min} \quad 16.36$ (a) time ${ }^{-}$
(b) $\mathrm{L} / \mathrm{mol} \cdot \mathrm{time}$
(c) $\mathrm{L}^{2} / \mathrm{mol}^{2} \cdot$ time
(d) $\mathrm{L}^{3 / 2} / \mathrm{mol}^{3 / 2} \cdot$ time
16.39(a) first order
(b) second order
(c) zero order $16.417 \mathrm{~s} \quad$ 16.43(a) $k=$
$0.0660 \mathrm{~min}^{-1}$
(b) 21.0 min

$$
k=3 \times 10^{-3} \mathrm{~s}^{-1}
$$

(b) $t_{1 / 2}=2 \times 10^{2} \mathrm{~s}$
16.47 Measure the rate constant at a series of temperatures and plot $\ln k$ versus $1 / T$. The slope of the line equals $-E_{\mathrm{a}} / R$.
E16.49 $083 \mathrm{~s}^{-1} \mathcal{1}^{16.53 \mathrm{No} \text {, other factors that affect the fraction }}$ of collisions that lead to reaction are the energy and orientation of the collisions. 16.56 No, reaction is reversible and will eventually reach a state where the forward and reverse rates are equal. When this occurs, there are no concentrations equal to zero. Since some reactants are reformed from EF, the amount of EF will be less than $4 \times 10^{-5}$ mol. 16.57 At the same temperature, both reaction mixtures have the same average kinetic energy, but not the same velocity. The trimethylamine molecule has greater mass than the ammonia molecule, so trimethylamine molecules will collide less often with HCl . Moreover, the bulky groups bonded to nitrogen in trimethylamine mean that collisions with HCl having the correct orientation occur less frequently. Therefore, the rate of the first reaction is higher. 16.5812 unique collisions $\quad 16.602 .96 \times 10^{-18}$
16.62(a)

(b) $2.70 \times 10^{2} \mathrm{~kJ} / \mathrm{mol}$
(c)

16.64(a) Because the enthalpy change is positive, the reaction is endothermic.

(b) 3 kJ
(c)

16.65 The rate of an overall reaction depends on the rate of the slowest step. The rate of the overall reaction will be lower than the average of the individual rates because the average includes higher rates as well. 16.69 The probability of three particles colliding with one another with the proper energy and orientation is much less than the probability for two particles. 16.70 No, the overall rate law must contain only reactants (no intermediates), and the overall rate is determined by the slow step.

# 16.72(a) $\mathrm{A}(g)+\mathrm{B}(g)+\mathrm{C}(g) \longrightarrow \mathrm{D}(g)$ 

(b) X and Y are intermediates.

\end{tabular}

(d) yes (e) yes $\quad 16.74$ The proposed mechanism is valid because the individual steps are chemically reasonable and add to give the overall equation. In addition, the rate law for the mechanism matches the observed rate law. 16.77 No. A catalyst changes the mechanism of a reaction to one with lower activation energy. Lower activation energy means a faster reaction. An increase in temperature does not influence the activation energy, but increases the fraction of collisions with sufficient energy to equal or exceed the activation energy. $\quad 16.78$ (a) No. The spark provides energy that is absorbed by the $\mathrm{H}_{2}$ and $\mathrm{O}_{2}$ molecules to achieve the activation energy. (b) Yes. The powdered metal acts as a heterogeneous catalyst, providing a surface on which the oxygen-hydrogen reaction can proceed with a lower activation energy.
16.82(a) Water does not appear as a reactant in the ratedetermining step.
(b) Step 1: $\quad$ rate $_{1}=k_{1}\left[\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr}\right]$

Step 2: $\quad \operatorname{rate}_{2}=k_{2}\left[\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}^{+}\right]$
Step 3: $\quad \operatorname{rate}_{3}=k_{3}\left[\left(\mathrm{CH}_{3}\right)_{3} \mathrm{COH}_{2}{ }^{+}\right]$
(c) $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}^{+}$and $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{COH}_{2}^{+}$
(d) The rate-determining step is step 1 . The rate law for this step agrees with the rate law observed with $k=k_{1}$.
$16.854 .61 \times 10^{4} \mathrm{~J} / \mathrm{mol} \quad 16.89$ (a) Rate increases 2.5 times.
(b) Rate is halved.
(c) Rate decreases by a factor of 0.01 .
(d) Rate does not change. 16.92 second order 16.947 times faster $16.9657 \mathrm{yr} \quad 16.99$ (a) $0.21 \mathrm{~h}^{-1} ; 3.3 \mathrm{~h} \quad$ (b) $6.6 \mathrm{~h} \quad$ (c) If the concentration of sucrose is relatively low, the concentration of water remains nearly constant even with small changes in the amount of water. This gives an apparent zero-order reaction with respect to water. Thus, the reaction is first order overall because the rate does not change with changes in the amount of water.

## Chapter 17

17.1 If the change is one of concentrations, it results temporarily in more products and less reactants. After equilibrium is reestablished, $K_{\mathrm{c}}$ remains unchanged because the ratio of products and reactants remains the same. If the change is one of temperature, [product] and $K_{\mathrm{c}}$ increase and [reactant] decreases.
17.7 The equilibrium constant expression is $K=\left[\mathrm{O}_{2}\right]$. If the temperature remains constant, $K$ remains constant. If the initial amount of $\mathrm{Li}_{2} \mathrm{O}_{2}$ present is sufficient to reach equilibrium, the amount of $\mathrm{O}_{2}$ obtained will be constant.

The value of $Q$ increases as a function of time until it reaches the value of $K$. (b) no $\quad 17.11$ Yes. If $Q_{1}$ is for the formation of
$1 \mathrm{~mol} \mathrm{NH}_{3}$ from $\mathrm{H}_{2}$ and $\mathrm{N}_{2}$, and $Q_{2}$ is for the formation of $\mathrm{NH}_{3}$ from $\mathrm{H}_{2}$ and 1 mol of $\mathrm{N}_{2}$, then $Q_{2}=Q_{1}{ }^{2}$.

## Chapter 18

18.2 All Arrhenius acids contain hydrogen in their formula and produce hydronium ion $\left(\mathrm{H}_{3} \mathrm{O}^{+}\right)$in aqueous solution. All Arrhenius bases produce hydroxide ion $\left(\mathrm{OH}^{-}\right)$in aqueous solution. Neutralization occurs when each $\mathrm{H}_{3} \mathrm{O}^{+}$ion combines with an
$\mathrm{OH}^{-}$ion to form two molecules of $\mathrm{H}_{2} \mathrm{O}$. Chemists found the reaction of any strong base with any strong acid always produced $56 \mathrm{~kJ} / \mathrm{mol}(\Delta H=-56 \mathrm{~kJ} / \mathrm{mol})$. $\quad 18.4$ Strong acids and bases dissociate completely into ions when dissolved in water. Weak acids and bases dissociate only partially. The characteristic property of all weak acids is that a significant number of the acid molecules are undissociated. 18.5 (a), (c), and (d)
18.7 (b) and (d)
18.9(a) $K_{\mathrm{a}}=\frac{\left[\mathrm{CN}^{-}\right]\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]}{[\mathrm{HCN}]}$

(c) weak acid
(d) weak acid
18.22(a) The acid with the smaller $K_{\mathrm{a}}\left(4 \times 10^{-5}\right)$ has the higher pH , because less dissociation yields fewer hydronium ions.
(b) The acid with the larger $\mathrm{p} K_{\mathrm{a}}$ (3.5) has the higher pH , because a larger $\mathrm{p} K_{\mathrm{a}}$ means a smaller $K_{\mathrm{a}}$. (c) Lower concentration $(0.01 M)$ gives fewer hydronium ions. (d) A $91 M$ weak acid
solution gives fewer hydronium ions. (e) The 0.01 Gase solusolution gives fewer hydronium ions. (e) The 0.01 $M$ base
tion has a lower concentration of hydronium ions. (f) The solution has $\mathrm{pOH}=6.0$ because $\mathrm{pH}=14.0-6.0=8.0$

$18.314 .8 \times 10^{-4} \mathrm{~mol} \mathrm{OH}^{-} / \mathrm{L} \quad 18.331 .4 \times 10^{-4} \mathrm{~mol} \mathrm{OH}^{-}$ 18.36(a) Rising temperature increases the value of $K_{\mathrm{w}}$. (b) $K_{\mathrm{w}}=$ $2.5 \times 10^{-14} ; \mathrm{pOH}=6.80 ;\left[\mathrm{OH}^{-}\right]=1.6 \times 10^{-7} \mathrm{M} \quad 18.37$ The Brønsted-Lowry theory defines acids as proton donors and bases as proton acceptors, while the Arrhenius definition looks at acids as containing ionizable hydrogen atoms and at bases as containing hydroxide ions. In both definitions, an acid produces hydronium ions and a base produces hydroxide ions when added to water. Ammonia and carbonate ion are two Brønsted-Lowry bases that are not Arrhenius bases because they do not contain hydroxide ions. Brønsted-Lowry acids must contain an ionizable hydrogen atom in order to be proton donors, so a Brønsted-Lowry acid is also an Arrhenius acid. 18.40 An amphiprotic substance is one that can lose a proton to act as an acid or gain a proton to act as a base. The dihydrogen phosphate ion, $\mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}$, is an example. $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q)+\mathrm{OH}^{-}(a q) \longrightarrow \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{HPO}_{4}{ }^{2-}(a q)$ $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}(a q)+\mathrm{HCl}(a q) \longrightarrow \mathrm{H}_{3} \mathrm{PO}_{4}(a q)+\mathrm{Cl}^{-}(a q)$

18.129 Since both bases produce $\mathrm{OH}^{-}$ions in water, both bases appear equally strong. $\mathrm{CH}_{3} \mathrm{O}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{OH}^{-}(a q)+$ $\mathrm{CH}_{3} \mathrm{OH}(a q)$ and $\mathrm{NH}_{2}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{OH}^{-}(a q)+$ $\mathrm{NH}_{3}(\mathrm{aq})$. 18.131 Ammonia, $\mathrm{NH}_{3}$, is a more basic solvent than $\mathrm{H}_{2} \mathrm{O}$. In a more basic solvent, weak acids such as HF act like strong acids and are $100 \%$ dissociated. 18.133 A Lewis acid is an electron-pair acceptor while a Brønsted-Lowry acid is a proton donor. The proton of a Brønsted-Lowry acid fits the definition of a Lewis acid because it accepts an electron pair when it bonds with a base. All Lewis acids are not BrønstedLowry acids. A Lewis base is an electron-pair donor and a Brønsted-Lowry base is a proton acceptor. All Brønsted-Lowry bases can be Lewis bases, and vice versa. 18.134(a) No, $\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}{ }^{2+}(a q)+6 \mathrm{NH}_{3}(a q) \rightleftharpoons \mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{6}{ }^{2+}+6 \mathrm{H}_{2} \mathrm{O}(l)$; $\mathrm{NH}_{3}$ is a weak Brønsted-Lowry base, but a strong Lewis base. (b) In an oxygen-deficient environment the equilibrium shifts to the left to release oxygen. (c) A decrease in $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$shifts the equilibrium to the right. More oxygen is absorbed, but it will be more difficult to remove the $\mathrm{O}_{2}$. (d) An increase in $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$shifts the equilibrium to the left. Less oxygen is bound to Hb , but it will be easier to remove it.
18.186(a) 1.012 M
(b) 0.004 M
(c) $0.4 \%$
18.187(a) 10.0 (b) The $\mathrm{p} K_{\mathrm{b}}$ for the $3^{\circ}$ amine group is much smaller than that for the aromatic ring, thus the $K_{\mathrm{b}}$ is significantly larger (yielding a much greater amount of $\mathrm{OH}^{-}$).
(c) 4.7
(d) 5.1

## Chapter 19

19.2 The acid component neutralizes added base and the base component neutralizes added acid, so the pH of the buffer solution remains relatively constant. The components of a buffer do not neutralize one another because they are a conjugate acid-base pair. 19.7 The buffer range, the pH over which the buffer acts
effectively, is greatest when the buffer-component ratio is 1 ; the range decreases as the component ratio deviates from 1. 19.9(a) Ratio and pH increase; added $\mathrm{OH}^{-}$reacts with HA. (b) Ratio and pH decrease; added $\mathrm{H}^{+}$reacts with $\mathrm{A}^{-}$. (c) Ratio and pH increase; added $\mathrm{A}^{-}$increases $\left[\mathrm{A}^{-}\right.$]. (d) Ratio and pH decrease; added HA increases [HA]. $\quad 19.11\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=$ $5.6 \times 10^{-6} M ; \mathrm{pH}=5.25 \quad 19.13\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=5.2 \times 10^{-4} \mathrm{M} ; \mathrm{pH}=$ $\begin{array}{llllll}3.28 & 19.15 & 3.89 & 19.17 & 10.03 & 19.19 \\ 9.47 & 19.21(\mathrm{a}) K_{\mathrm{a} 2}\end{array}$ (b) $10.55 \quad 19.233 .6 \quad 19.250 .20 \quad 19.273 .37 \quad 19.298 .82$ 19.31(a) 4.81 (b) $0.49 \mathrm{~g} \mathrm{KOH} \quad 19.33$ (a) $\mathrm{HOOC}\left(\mathrm{CH}_{2}\right)_{4} \mathrm{COOH} /$ $\mathrm{HOOC}\left(\mathrm{CH}_{2}\right)_{4} \mathrm{COO}^{-}$or $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3}^{+} / \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}$
(b) $\mathrm{H}_{2} \mathrm{PO}_{4}^{-} / \mathrm{HPO}_{4}{ }^{2-}$ or $\mathrm{H}_{2} \mathrm{ASO}_{4}^{-} / \mathrm{HASO}_{4}{ }^{2-}$
19.35(a) $\mathrm{HOCH}_{2} \mathrm{CH}(\mathrm{OH}) \mathrm{COOH} / \mathrm{HOCH}_{2} \mathrm{CH}(\mathrm{OH}) \mathrm{COO}^{-}$or $\mathrm{CH}_{3} \mathrm{COOC}_{6} \mathrm{H}_{4} \mathrm{COOH} / \mathrm{CH}_{3} \mathrm{COOC}_{6} \mathrm{H}_{4} \mathrm{COO}^{-}$
(b) $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N} / \mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NH}^{+} \quad 19.381 .6 \quad 19.40$ To see a distinct color in a mixture of two colors, you need one to have about 10 times the intensity of the other. For this to be the case, the concentration ratio $[\mathrm{HIn}] /\left[\mathrm{In}^{-}\right]$has to be greater than $10 / 1$ or less than $1 / 10$. This occurs when $\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}-1$ or $\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+1$, respectively, giving a pH range of about two units. 19.42 The equivalence point in a titration is the point at which the number of moles of base equals the number of moles of acid. The endpoint is the point at which the added indicator changes color. If an appropriate indicator is selected, the endpoint is close to the equivalence point, but they are not usually the same. The endpoint, or color change, may precede or follow the equivalence point, depending on the indicator chosen. $\quad 19.44(\mathrm{a})$ initial pH : strong acid-strong base $<$ weak acid-strong base $<$ strong acid-weak base (b) pH at equivalence point: strong acid-weak base $<$ strong acid-strong base $<$ weak acid-stryenebase PDF 19.46 At the center of the buffer region, the concentrations of weak acid and conjugate base are equal, so the $\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}$ of the acid. $\quad 19.48 \mathrm{pH}$ range from 7.5 to $9.5 \quad$ 19.50(a) bromthymol blue (b) thymol blue or phenolphthalein 19.52(a) methyl red $\begin{array}{llll}\text { (b) bromthymol blue } 19.54 \text { (a) } 1.0000 & \text { (b) } 1.6368 & \text { (c) } 2.898\end{array}$ (d) 3.903
(e) 7.00

(d) 6.09
(e) 7.41
(f) $8.76 \quad(\mathrm{~g}) 10.10$
(h) 12.05
19.58(a) 59.0 mL and 8.54
(b) 66.0 mL and 7.13 , total 132.1 mL and $9.69 \quad$ 19.60(a) 123 mL and 5.17 (b) 194 mL and 5.80 19.63 Fluoride ion is the conjugate base of a weak acid and reacts with $\mathrm{H}_{2} \mathrm{O}: \mathrm{F}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons$
$\mathrm{HF}(a q)+\mathrm{OH}^{-}(a q)$. As the pH increases, the equilibrium shifts to the left and $\left[\mathrm{F}^{-}\right]$increases. As the pH decreases, the equilibrium shifts to the right and $\left[\mathrm{F}^{-}\right]$decreases. The changes in $\left[\mathrm{F}^{-}\right]$ influence the solubility of $\mathrm{BaF}_{2}$. Chloride ion is the conjugate base of a strong acid, so it does not react with water and its concentration is not influenced by pH . 19.65 The compound precipitates. $19.66(\mathrm{a}) K_{\mathrm{sp}}=\left[\mathrm{Ag}^{+}\right]^{2}\left[\mathrm{CO}_{3}{ }^{2-}\right] \quad$ (b) $K_{\mathrm{sp}}=$ $\left[\mathrm{Ba}^{2+}\right]\left[\mathrm{F}^{-}\right]^{2}$ (c) $K_{\text {sp }}=\left[\mathrm{Cu}^{2+}\right]\left[\mathrm{HS}^{-}\right]\left[\mathrm{OH}^{-}\right] \quad$ 19.68(a) $K_{\text {sp }}=$ $\left[\mathrm{Ca}^{2+}\right]\left[\mathrm{CrO}_{4}{ }^{2-}\right]$ (b) $K_{\mathrm{sp}}=\left[\mathrm{Ag}^{+}\right]\left[\mathrm{CN}^{-}\right] \quad$ (c) $K_{\mathrm{sp}}=$
$\left[\begin{array}{lllll}{\left[\mathrm{Ni}^{2+}\right]\left[\mathrm{HS}^{-}\right]\left[\mathrm{OH}^{-}\right]} & 19.70 & 1.3 \times 10^{-4} & 19.72 & 2.8 \times 10^{-11}\end{array}\right.$
19.74(a) $2.3 \times 10^{-5} M \quad$ (b) $4.2 \times 10^{-9} M \quad 19.76$ (a) $1.7 \times 10^{-3} M$ $\begin{array}{llll}\text { (b) } 2.0 \times 10^{-4} M & 19.78 \text { (a) } \mathrm{Mg}(\mathrm{OH})_{2} & \text { (b) } \mathrm{PbS} & \text { (c) } \mathrm{Ag}_{2} \mathrm{SO}_{4}\end{array}$
19.80 (a) $\mathrm{CaSO}_{4}$
(b) $\mathrm{Mg}_{3}\left(\mathrm{PO}_{4}\right)_{2} \quad$ (c) $\mathrm{PbSO}_{4}$
19.82(a) $\mathrm{AgCl}(s) \rightleftharpoons \mathrm{Ag}^{+}(a q)+\mathrm{Cl}^{-}(a q)$. The chloride ion is the anion of a strong acid, so it does not react with $\mathrm{H}_{3} \mathrm{O}^{+}$. No change with pH . (b) $\mathrm{SrCO}_{3}(s) \rightleftharpoons \mathrm{Sr}^{2+}(a q)+\mathrm{CO}_{3}{ }^{2-}(a q)$. The strontium ion is the cation of a strong base, so pH will not affect its solubility. The carbonate ion acts as a base:
$\mathrm{CO}_{3}^{2-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{HCO}_{3}^{-}(a q)+\mathrm{OH}^{-}(a q)$; also $\mathrm{CO}_{2}(g)$ forms and escapes: $\mathrm{CO}_{3}^{2-}(a q)+2 \mathrm{H}_{3} \mathrm{O}^{+}(a q) \longrightarrow$
$\mathrm{CO}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)$. Therefore, the solubility of $\mathrm{SrCO}_{3}$ will
increase with addition of $\mathrm{H}_{3} \mathrm{O}^{+}$(decreasing pH ).
19.84(a) $\mathrm{Fe}(\mathrm{OH})_{2}(s) \rightleftharpoons \mathrm{Fe}^{2+}(a q)+2 \mathrm{OH}^{-}(a q)$. The $\mathrm{OH}^{-}$ ion reacts with added $\mathrm{H}_{3} \mathrm{O}^{+}: \mathrm{OH}^{-}(a q)+\mathrm{H}_{3} \mathrm{O}^{+}(a q) \longrightarrow$ $2 \mathrm{H}_{2} \mathrm{O}(l)$. The added $\mathrm{H}_{3} \mathrm{O}^{+}$consumes the $\mathrm{OH}^{-}$, driving the equilibrium toward the right to dissolve more $\mathrm{Fe}(\mathrm{OH})_{2}$. Solubility increases with addition of $\mathrm{H}_{3} \mathrm{O}^{+}$(decreasing pH).
(b) $\mathrm{CuS}(s)+\mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{Cu}^{2+}(a q)+\mathrm{HS}^{-}(a q)+\mathrm{OH}^{-}(a q)$. Both $\mathrm{HS}^{-}$and $\mathrm{OH}^{-}$are anions of weak acids, so both ions react with added $\mathrm{H}_{3} \mathrm{O}^{+}$. Solubility increases with addition of $\mathrm{H}_{3} \mathrm{O}^{+}$ (decreasing pH ). $\quad 19.86$ yes $\quad 19.88$ yes $\quad 19.91$ (a) $\mathrm{Fe}(\mathrm{OH})_{3}$ (b) The two metal ions are separated by adding just enough NaOH to precipitate iron(III) hydroxide. (c) $2.0 \times 10^{-7} \mathrm{M}$ 19.94 No, because it indicates that a complex ion forms between the lead ion and hydroxide ions: $\mathrm{Pb}^{2+}(a q)+n \mathrm{OH}^{-}(a q) \rightleftharpoons$ $\mathrm{Pb}(\mathrm{OH})_{n}{ }^{2-n}(a q) \quad 19.95 \mathrm{Hg}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}{ }^{2+}(a q)+4 \mathrm{CN}^{-}(a q)$ $\mathrm{Hg}(\mathrm{CN})_{4}{ }^{2-}(a q)+4 \mathrm{H}_{2} \mathrm{O}(l) \quad 19.97 \mathrm{Ag}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}{ }^{+}(a q)+$ $2 \mathrm{~S}_{2} \mathrm{O}_{3}{ }^{2-}(a q) \rightleftharpoons \mathrm{Ag}\left(\mathrm{S}_{2} \mathrm{O}_{3}\right)_{2}{ }^{3-}(a q)+2 \mathrm{H}_{2} \mathrm{O}(l)$ $19.998 .1 \times 10^{-15} M \quad 19.1010 .05 M \quad 19.1031 .0 \times 10^{-16} M$ $\mathrm{Zn}^{2+} ; 0.025 \mathrm{M} \mathrm{Zn}(\mathrm{CN})_{4}{ }^{2-} ; 0.049 \mathrm{M} \mathrm{CN}^{-} \quad 19.1050 .035 \mathrm{~L}$ of 2.00 M NaOH and 0.465 L of $0.200 \mathrm{MHCOOH} \quad 19.107$ (a) 0.99 (b) Assuming the volumes are additive: 0.468 L of 1.0 M

(b)

Maximum slope (equivalence point) is at $V_{\mathrm{avg}}=40.00 \mathrm{~mL}$.
$19.128 K_{\mathrm{b}}=\frac{\left[\mathrm{BH}^{+}\right]\left[\mathrm{OH}^{-}\right]}{[\mathrm{B}]}$
Rearranging to isolate $\left[\mathrm{OH}^{-}\right]$:
$\left[\mathrm{OH}^{-}\right]=K_{\mathrm{b}} \frac{[\mathrm{B}]}{\left[\mathrm{BH}^{+}\right]}$
Taking the negative log:

$$
\begin{aligned}
& -\log \left[\mathrm{OH}^{-}\right]=-\log K_{\mathrm{b}}-\log \frac{[\mathrm{B}]}{\left[\mathrm{BH}^{+}\right]} \\
& \text {Therefore, } \mathrm{pOH}=\mathrm{p} K_{\mathrm{b}}+\log \frac{\left[\mathrm{BH}^{+}\right]}{[\mathrm{B}]}
\end{aligned}
$$

## Chapter 20

20.2 A spontaneous process occurs by itself, whereas a nonspontaneous process requires a continuous input of energy to make it happen. It is possible to cause a nonspontaneous process to occur, but the process stops once the energy source is removed. A reaction that is nonspontaneous under one set of conditions may be spontaneous under a different set of conditions.
20.5 The transition from liquid to gas involves a greater increase in dispersal of energy and freedom of motion than does the transition from solid to liquid. 20.6 In an exothermic reaction.
$\Delta S_{\text {surr }}>0$. In an endothermic reaction, $\Delta S_{\text {surr }}<\boldsymbol{Q}$. A chemical cold pack for injuries is an example of an application using a spontaneous endothermic process. 20.8(a), (b), and (c) 20.10 (a) and (b) 20.12 (a) positive (b) negative (c) negative 20.14(a) positive (b) positive (c) positive 20.16(a) negative (b) negative (c) positive 20.18(a) positive (b) negative (c) positive 20.20 (a) positive (b) negative (c) positive 20.22(a) Butane. The double bond in 2-butene restricts freedom of rotation. (b) $\mathrm{Xe}(g)$. It has the greater molar mass. (c) $\mathrm{CH}_{4}(g)$. Gases have greater entropy than liquids. 20.24(a) $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(l)$. It is a more complex molecule. (b) $\mathrm{KClO}_{3}(a q)$. Ions in solution have their energy more dispersed than those in a solid. (c) $\mathrm{K}(s)$. It has a greater molar mass. $\quad$ 20.26(a) Diamond $<$ graphite $<$ charcoal. Freedom of motion is least in the network solid; more freedom between graphite sheets; most freedom in amorphous solid. (b) Ice $<$ liquid water $<$ water vapor. Entropy increases as a substance changes from solid to liquid to gas. (c) O atoms $<$ $\mathrm{O}_{2}<\mathrm{O}_{3}$. Entropy increases with molecular complexity.
20.28(a) $\mathrm{ClO}_{4}^{-}(a q)>\mathrm{ClO}_{3}{ }^{-}(\mathrm{aq})>\mathrm{ClO}_{2}^{-}(a q)$; decreasing molecular complexity (b) $\mathrm{NO}_{2}(g)>\mathrm{NO}(g)>\mathrm{N}_{2}(g)$. $\mathrm{N}_{2}$ has lower standard molar entropy because it consists of two of the same atoms; the other species have two different types of atoms. $\mathrm{NO}_{2}$ is more complex than NO. (c) $\mathrm{Fe}_{3} \mathrm{O}_{4}(s)>\mathrm{Fe}_{2} \mathrm{O}_{3}(s)>$ $\mathrm{Al}_{2} \mathrm{O}_{3}(s) . \mathrm{Fe}_{3} \mathrm{O}_{4}$ is more complex and more massive. $\mathrm{Fe}_{2} \mathrm{O}_{3}$ is more massive than $\mathrm{Al}_{2} \mathrm{O}_{3}$. 20.31 For a system at equilibrium, $\Delta S_{\text {univ }}=\Delta S_{\text {sys }}+\Delta S_{\text {surr }}=0$. For a system moving to equilibrium, $\Delta S_{\text {univ }}>0 . \quad 20.32 S_{\mathrm{Cl}_{2} \mathrm{O}(g)}^{\circ}=2 S_{\mathrm{HClO}(g)}^{\circ}-S_{\mathrm{H}_{2} \mathrm{O}(g)}^{\circ}-\Delta S_{\mathrm{rxn}}^{\circ}$ 20.33(a) negative; $\Delta S^{\circ}=-172.4 \mathrm{~J} / \mathrm{K} \quad$ (b) positive; $\Delta S^{\circ}=$ $141.6 \mathrm{~J} / \mathrm{K} \quad$ (c) negative; $\Delta S^{\circ}=-837 \mathrm{~J} / \mathrm{K} \quad 20.35 \Delta S^{\circ}=$
$93.1 \mathrm{~J} / \mathrm{K}$; yes, the positive sign of $\Delta S$ is expected because there is a net increase in the number of gas molecules. $20.37 \Delta S^{\circ}=$ $-311 \mathrm{~J} / \mathrm{K}$; yes, the negative entropy change matches the decrease in moles of gas. $\quad 20.39-75.6 \mathrm{~J} / \mathrm{K} \quad 20.41-242 \mathrm{~J} / \mathrm{K}$
$20.44-97.2 \mathrm{~J} / \mathrm{K} \quad 20.46$ A spontaneous process has $\Delta S_{\text {univ }}>0$. Since the absolute temperature is always positive, $\Delta G_{\text {sys }}$ must be negative $\left(\Delta G_{\text {sys }}<0\right)$ for a spontaneous process. $20.48 \Delta H_{\mathrm{rxn}}^{\circ}$ is positive and $\Delta S_{\text {sys }}^{\circ}$ is positive. Melting is an example. 20.49 The entropy changes little within a phase. As long as the substance does not change phase, the value of $\Delta S^{\circ}$ is relatively unaffected by temperature. $2 \mathbf{2 0 . 5 0}$ (a) -1138.0 kJ (b) -1379.4 kJ (c) $-224 \mathrm{~kJ} \quad$ 20.52(a) $-1138 \mathrm{~kJ} \quad$ (b) $-1379 \mathrm{~kJ} \quad$ (c) -226 kJ
20.54(a) Entropy decreases ( $\Delta S^{\circ}$ is negative) because the number of moles of gas decreases. The combustion of CO releases energy ( $\Delta H^{\circ}$ is negative). (b) -257.2 kJ or -257.3 kJ , depending on the method $20.56(\mathrm{a})-0.409 \mathrm{~kJ} / \mathrm{mol} \cdot \mathrm{K} \quad$ (b) $-197 \mathrm{~kJ} / \mathrm{mol}$ 20.58(a) $\Delta H_{\mathrm{rxn}}^{\circ}=90.7 \mathrm{~kJ} ; \Delta S_{\mathrm{rxn}}^{\circ}=221 \mathrm{~J} / \mathrm{K} \quad$ (b) at $28^{\circ} \mathrm{C}, \Delta G^{\circ}=$ 24.3 kJ ; at $128^{\circ} \mathrm{C}, \Delta G^{\circ}=2.2 \mathrm{~kJ}$; at $228^{\circ} \mathrm{C}, \Delta G^{\circ}=-19.9 \mathrm{~kJ}$
(c) For the substances in their standard states, the reaction is nonspontaneous at $28^{\circ} \mathrm{C}$, near equilibrium at $128^{\circ} \mathrm{C}$, and spontaneous at $228^{\circ} \mathrm{C} . \quad 20.60 \Delta H^{\circ}=30910 \mathrm{~J}, \Delta S^{\circ}=93.15 \mathrm{~J} / \mathrm{K}, T=331.8 \mathrm{~K}$ 20.62(a) $\Delta H_{\mathrm{rxn}}^{\circ}=-241.826 \mathrm{~kJ}, \Delta S_{\mathrm{rxn}}^{\circ}=-44.4 \mathrm{~J} / \mathrm{K}, \Delta G_{\mathrm{rxn}}^{\circ}=$ -228.60 kJ (b) Yes. The reaction will become nonspontaneous at higher temperatures. (c) The reaction is spontaneous below $5.45 \times 10^{3} \mathrm{~K} . \quad 20.64$ (a) $\Delta G^{\circ}$ is a relatively large positive value. (b) $K \gg 1$. $Q$ depends on initial conditions, not equilibrium conditions. 20.67 The standard free energy change, $\Delta G^{\circ}$, applies when all components of the system are in their standard states; $\Delta G^{\circ}=\Delta G$ when all concentrations equal $1 M$ and all
Epartialtressures equal 1 atm . 20.68(a) $1.7 \times 10^{6}$
(b) $3.89 \times 10$
(c) $1.26 \times 10^{48} \quad 20.70$ (a) $6.57 \times 10^{173}$
(b) $4.46 \times 10^{-15}$
(c) $3.46 \times 10^{4} \quad 20.724 .89 \times 10^{-51}$
$20.743 .36 \times 10^{5} \quad 20.762 .7 \times 10^{4} \mathrm{~J} / \mathrm{mol}$; no
20.78(a) $2.9 \times 10^{4} \mathrm{~J} / \mathrm{mol}$ (b) The reverse direction, formation of reactants, is spontaneous, so the reaction proceeds to the left. (c) $7.0 \times 10^{3} \mathrm{~J} / \mathrm{mol}$; the reaction proceeds to the left to reach equilibrium. $\quad$ 20.80(a) no $T \quad$ (b) $163 \mathrm{~kJ} \quad$ (c) $1 \times 10^{2} \mathrm{~kJ} / \mathrm{mol}$ 20.83(a) spontaneous (b) + (c) + (d) - (e) - , not spontaneous (f) -20.87 (a) $2.3 \times 10^{2} \quad$ (b) Administer oxygen-rich air to counteract the CO poisoning. $\quad 20.90-370$. kJ
20.92(a) $2 \mathrm{~N}_{2} \mathrm{O}_{5}(g)+6 \mathrm{~F}_{2}(g) \longrightarrow 4 \mathrm{NF}_{3}(g)+5 \mathrm{O}_{2}(g)$
(b) $\Delta G_{\mathrm{rxn}}^{\circ}=-569 \mathrm{~kJ} \quad$ (c) $\Delta G_{\mathrm{rxn}}=-5.60 \times 10^{2} \mathrm{~kJ} / \mathrm{mol}$
$20.95 \Delta H_{\mathrm{rxn}}^{\circ}=-137.14 \mathrm{~kJ} ; \Delta S_{\mathrm{rxn}}^{\circ}=-120.3 \mathrm{~J} / \mathrm{K} ; \Delta G_{\mathrm{rxn}}^{\circ}=$ $-101.25 \mathrm{~kJ} \quad 20.100$ (a) $1.203 \times 10^{23}$ molecules ATP/g glucose (b) $3.073 \times 10^{23}$ molecules ATP $/ \mathrm{g}$ tristearin 20.106 (a) $1.67 \times 10^{3}$ $\mathrm{J} / \mathrm{mol}$ (b) $7.37 \times 10^{3} \mathrm{~J} / \mathrm{mol}$ (c) $-4.04 \times 10^{3} \mathrm{~J} / \mathrm{mol}$ (d) 0.19 20.110 (a) $465 \mathrm{~K} \quad$ (b) $6.59 \times 10^{-4}$ (c) The reaction rate is higher at the higher temperature. The shorter time required (kinetics) overshadows the lower yield (thermodynamics).

## Chapter 21

21.1 Oxidation is the loss of electrons and results in a higher oxidation number; reduction is the gain of electrons and results in a lower oxidation number. $\quad 21.3$ No, one half-reaction cannot take place independently because there is a transfer of electrons from one substance to another. If one substance loses electrons, another substance must gain them. 21.6 To remove $\mathrm{H}^{+}$ions from an equation, add an equal number of $\mathrm{OH}^{-}$ions to both sides to neutralize the $\mathrm{H}^{+}$ions and produce water. 21.8 Spontaneous
reactions, for which $\Delta G_{\text {sys }}<0$, take place in voltaic cells (also called galvanic cells). Nonspontaneous reactions, for which $\Delta G_{\text {sys }}>0$, take place in electrolytic cells. $\quad 21.10$ (a) $\mathrm{Cl}^{-}$
(b) $\mathrm{MnO}_{4}^{-}$
(c) $\mathrm{MnO}_{4}{ }^{-}$
(d) $\mathrm{Cl}^{-}$
(e) from $\mathrm{Cl}^{-}$to $\mathrm{MnO}_{4}^{-}$
(f) $8 \mathrm{H}_{2} \mathrm{SO}_{4}(a q)+2 \mathrm{KMnO}_{4}(a q)+10 \mathrm{KCl}(a q)$
$2 \mathrm{MnSO}_{4}(a q)+5 \mathrm{Cl}_{2}(g)+8 \mathrm{H}_{2} \mathrm{O}(l)+6 \mathrm{~K}_{2} \mathrm{SO}_{4}(a q)$
21.12(a) $\mathrm{ClO}_{3}^{-}(a q)+6 \mathrm{H}^{+}(a q)+6 \mathrm{I}^{-}(a q) \longrightarrow$

$$
\mathrm{Cl}^{-}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l)+3 \mathrm{I}_{2}(s)
$$

Oxidizing agent is $\mathrm{ClO}_{3}{ }^{-}$and reducing agent is $\mathrm{I}^{-}$.
(b) $2 \mathrm{MnO}_{4}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l)+3 \mathrm{SO}_{3}{ }^{2-}(a q) \longrightarrow$

$$
2 \mathrm{MnO}_{2}(s)+3 \mathrm{SO}_{4}^{2-}(a q)+2 \mathrm{OH}^{-}(a q)
$$

Oxidizing agent is $\mathrm{MnO}_{4}{ }^{-}$and reducing agent is $\mathrm{SO}_{3}{ }^{2-}$.
(c) $2 \mathrm{MnO}_{4}^{-}(a q)+6 \mathrm{H}^{+}(a q)+5 \mathrm{H}_{2} \mathrm{O}_{2}(a q) \longrightarrow$

$$
2 \mathrm{Mn}^{2+}(a q)+8 \mathrm{H}_{2} \mathrm{O}(l)+5 \mathrm{O}_{2}(g)
$$

Oxidizing agent is $\mathrm{MnO}_{4}{ }^{-}$and reducing agent is $\mathrm{H}_{2} \mathrm{O}_{2}$.
21.14(a) $\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(a q)+14 \mathrm{H}^{+}(a q)+3 \mathrm{Zn}(s) \longrightarrow$

$$
2 \mathrm{Cr}^{3+}(a q)+7 \mathrm{H}_{2} \mathrm{O}(l)+3 \mathrm{Zn}^{2+}(a q)
$$

Oxidizing agent is $\mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}$ and reducing agent is Zn .
(b) $\mathrm{MnO}_{4}^{-}(a q)+3 \mathrm{Fe}(\mathrm{OH})_{2}(s)+2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$

$$
\mathrm{MnO}_{2}(s)+3 \mathrm{Fe}(\mathrm{OH})_{3}(s)+\mathrm{OH}^{-}(a q)
$$

Oxidizing agent is $\mathrm{MnO}_{4}{ }^{-}$and reducing agent is $\mathrm{Fe}(\mathrm{OH})_{2}$.
(c) $2 \mathrm{NO}_{3}^{-}(a q)+12 \mathrm{H}^{+}(a q)+5 \mathrm{Zn}(s) \longrightarrow$

$$
\mathrm{N}_{2}(g)+6 \mathrm{H}_{2} \mathrm{O}(l)+5 \mathrm{Zn}^{2+}(a q)
$$

Oxidizing agent is $\mathrm{NO}_{3}^{-}$and reducing agent is Zn .
21.16(a) $4 \mathrm{NO}_{3}^{-}{ }^{-}(a q)+4 \mathrm{H}^{+}(a q)+4 \mathrm{Sb}(s) \longrightarrow$

$$
4 \mathrm{NO}(g)+2 \mathrm{H}_{2} \mathrm{O}(l)+\mathrm{Sb}_{4} \mathrm{O}_{6}(s)
$$

Oxidizing agent is $\mathrm{NO}_{3}{ }^{-}$and reducing agent is Sb .
(b) $5 \mathrm{BiO}_{3}^{-}(a q)+14 \mathrm{H}^{+}(a q)+2 \mathrm{Mn}^{2+}(a q) \longrightarrow$

$$
5 \mathrm{Bi}^{++}(a q)+7 \mathrm{H}_{2} \mathrm{Q}(9) \sigma 2 \mathrm{An} \mathrm{H}^{-}(q q) \mathrm{DE}
$$

Oxidizing agent is $\mathrm{BiO}_{3}{ }^{-}$and reducing agent is $\mathrm{Mn}^{2+}$.
(c) $\mathrm{Pb}(\mathrm{OH})_{3}{ }^{-}(a q)+2 \mathrm{Fe}(\mathrm{OH})_{2}(s) \longrightarrow$

$$
\mathrm{Pb}(s)+2 \mathrm{Fe}(\mathrm{OH})_{3}(s)+\mathrm{OH}^{-}(a q)
$$

Oxidizing agent is $\mathrm{Pb}(\mathrm{OH})_{3}{ }^{-}$and reducing agent is $\mathrm{Fe}(\mathrm{OH})_{2}$.
21.18(a) $5 \mathrm{As}_{4} \mathrm{O}_{6}(s)+8 \mathrm{MnO}_{4}{ }^{-}(a q)+18 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$

$$
20 \mathrm{AsO}_{4}^{3-}(a q)+8 \mathrm{Mn}^{2+}(a q)+36 \mathrm{H}^{+}(a q)
$$

Oxidizing agent is $\mathrm{MnO}_{4}^{-}$and reducing agent is $\mathrm{As}_{4} \mathrm{O}_{6}$.
(b) $\mathrm{P}_{4}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$

$$
2 \mathrm{HPO}_{3}{ }^{2-}(a q)+2 \mathrm{PH}_{3}(g)+4 \mathrm{H}^{+}(a q)
$$

$\mathrm{P}_{4}$ is both the oxidizing agent and the reducing agent.
(c) $2 \mathrm{MnO}_{4}^{-}(a q)+3 \mathrm{CN}^{-}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$
$2 \mathrm{MnO}_{2}(s)+3 \mathrm{CNO}^{-}(a q)+2 \mathrm{OH}^{-}(a q)$
Oxidizing agent is $\mathrm{MnO}_{4}^{-}$and reducing agent is $\mathrm{CN}^{-}$.
21.21(a) $\mathrm{Au}(s)+3 \mathrm{NO}_{3}^{-}(a q)+4 \mathrm{Cl}^{-}(a q)+6 \mathrm{H}^{+}(a q) \longrightarrow$ $\mathrm{AuCl}_{4}^{-}(a q)+3 \mathrm{NO}_{2}(g)+3 \mathrm{H}_{2} \mathrm{O}(l) \quad$ (b) Oxidizing agent is $\mathrm{NO}_{3}{ }^{-}$and reducing agent is Au . (c) HCl provides chloride ions that combine with the gold(III) ion to form the stable $\mathrm{AuCl}_{4}{ }^{-}$ion.
21.22(a) A
(b) E
(c) $\mathrm{C} \quad$ (d) A
(e) E
(f) $\mathrm{E} \quad 21.25 \mathrm{An} \mathrm{ac-}$ tive electrode is a reactant or product in the cell reaction. An inactive electrode does not take part in the reaction and is present only to conduct a current. Platinum and graphite are commonly used as inactive electrodes. 21.26(a) A (b) B $\quad$ (c) A
(d) Hydrogen bubbles will form when metal A is placed in acid. Metal A is a better reducing agent than metal B , so if metal B reduces $\mathrm{H}^{+}$in acid, then metal A will also.
21.27(a) Oxidation: $\mathrm{Zn}(s) \longrightarrow \mathrm{Zn}^{2+}(a q)+2 \mathrm{e}^{-}$
$\begin{aligned} & \text { Reduction: } \mathrm{Sn}^{2+}(a q)+2 \mathrm{e}^{-} \xrightarrow{ } \\ & \\ & \text { Overall: } \mathrm{Zn}(s)+\mathrm{Sn}^{2+}(a q) \longrightarrow \mathrm{Zn}^{2+}(a q)+\mathrm{Sn}(s)\end{aligned}$
(b)

21.29(a) left to right $\quad$ (b) left $\quad$ (c) right $\quad$ (d) $\mathrm{Ni} \quad$ (e) Fe (f) $\mathrm{Fe} \quad$ (g) $1 M \mathrm{NiSO}_{4} \quad$ (h) $\mathrm{K}^{+}$and $\mathrm{NO}_{3}^{-} \quad$ (i) neither (j) from right to left
(k) Oxidation: $\mathrm{Fe}(s) \longrightarrow \mathrm{Fe}^{2+}(a q)+2 \mathrm{e}^{-}$

Reduction: $\mathrm{Ni}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Ni}(s)$
Overall: $\mathrm{Fe}(s)+\mathrm{Ni}^{2+}(a q) \longrightarrow \mathrm{Fe}^{2+}(a q)+\mathrm{Ni}(s)$
21.31(a) Reduction: $\mathrm{Fe}^{2+}(a q)+2 \mathrm{e}^{-} \longrightarrow \mathrm{Fe}(s)$ Oxidation: $\mathrm{Mn}(s) \longrightarrow \mathrm{Mn}^{2+}(a q)+2 \mathrm{e}^{-}$
Overall: $\mathrm{Fe}^{2+}(a q)+\mathrm{Mn}(s) \longrightarrow \mathrm{Fe}(s)+\mathrm{Mn}^{2+}(a q)$
(b)

21.33(a) $\mathrm{Al}(s)\left|\mathrm{Al}^{3+}(a q) \| \mathrm{Cr}^{3+}(a q)\right| \mathrm{Cr}(s)$
(b) $\mathrm{Pt}(s)\left|\mathrm{SO}_{2}(g)\right| \mathrm{SO}_{4}{ }^{2-}(a q), \mathrm{H}^{+}(a q) \| \mathrm{Cu}^{2+}(a q) \mid \mathrm{Cu}(s)$
21.36 A negative $E_{\text {cell }}^{\circ}$ indicates that the redox reaction is not spontaneous, that is, $\Delta G^{\circ}>0$. The reverse reaction is spontaneous with $E_{\mathrm{cell}}^{\circ}>0$. 21.37 Similar to other state functions, $E^{\circ}$ changes sign when a reaction is reversed. Unlike $\Delta G^{\circ}, \Delta H^{\circ}$, and $S^{\circ}, E^{\circ}$ (the ratio of energy to charge) is an intensive property. When the coefficients in a reaction are multiplied by a factor, the values of $\Delta G^{\circ}, \Delta H^{\circ}$, and $S^{\circ}$ are multiplied by that factor. However, $E^{\circ}$ does not change because both the energy and charge are multiplied by the factor and thus their ratio remains unchanged.
21.38(a) Oxidation: $\mathrm{Se}^{2-}(a q) \longrightarrow \mathrm{Se}(s)+2 \mathrm{e}^{-}$

Reduction: $2 \mathrm{SO}_{3}{ }^{2-}(a q)+3 \mathrm{H}_{2} \mathrm{O}(l)+4 \mathrm{e}^{-} \longrightarrow$

Oxidizing agent: $\mathrm{PbSO}_{4}<\mathrm{Pt}^{2+}<\mathrm{HClO}$
Reducing agent: $\mathrm{Cl}_{2}<\mathrm{Pt}<\mathrm{Pb}$
21.50 Yes; $\mathrm{C}>\mathrm{A}>\mathrm{B} \quad 21.53 \mathrm{~A}(s)+\mathrm{B}^{+}(a q) \longrightarrow \mathrm{A}^{+}(a q)+$ $\mathrm{B}(s)$ with $Q=\left[\mathrm{A}^{+}\right] /\left[\mathrm{B}^{+}\right]$. (a) $\left[\mathrm{A}^{+}\right]$increases and $\left[\mathrm{B}^{+}\right]$ decreases. (b) $E_{\text {cell }}$ decreases. (c) $E_{\text {cell }}=E_{\text {cell }}^{\circ}-(R T / n F)$ $\ln \left(\left[\mathrm{A}^{+}\right] /\left[\mathrm{B}^{+}\right]\right) ; E_{\text {cell }}=E_{\text {cell }}^{\circ}$ when $(R T / n F) \ln \left(\left[\mathrm{A}^{+}\right] /\left[\mathrm{B}^{+}\right]\right)=0$. This occurs when $\ln \left(\left[\mathrm{A}^{+}\right] /\left[\mathrm{B}^{+}\right]\right)=0$, that is, $\left[\mathrm{A}^{+}\right]$equals $\left[\mathrm{B}^{+}\right]$. (d) Yes, when $\left[\mathrm{A}^{+}\right]>\left[\mathrm{B}^{+}\right] . \quad 21.55$ In a concentration cell, the overall reaction decreases the concentration of the more concentrated electrolyte because it is reduced in the gathode eomparmer. 21.56(a) $3 \times 10^{35}$ (b) $4 \times 10^{-31} \quad 21.58$ (a) $1 \times 10^{-6} \quad$ (b) $6 \times 10^{9}$ 21.60 (a) $-2.03 \times 10^{5} \mathrm{~J} \quad$ (b) $1.73 \times 10^{5} \mathrm{~J} \quad 21.62$ (a) $-3.82 \times 10^{5} \mathrm{~J}$ (b) $-5.6 \times 10^{4} \mathrm{~J} \quad 21.64 \Delta G^{\circ}=-2.7 \times 10^{4} \mathrm{~J} ; E^{\circ}=0.28 \mathrm{~V}$ $21.66 E_{\text {cell }}^{\circ}=0.054 \mathrm{~V} ; \Delta G^{\circ}=-1.0 \times 10^{4} \mathrm{~J} \quad 21.688 .8 \times 10^{-5} \mathrm{M}$ 21.70 (a) 0.05 V (b) 0.50 M (c) $\left[\mathrm{Co}^{2+}\right]=0.91 \mathrm{M} ;\left[\mathrm{Ni}^{2+}\right]=$ 0.09 M $\quad 21.72 \mathrm{~A} ; 0.083 \mathrm{~V} \quad 21.74$ Electrons flow from the anode, where oxidation occurs, to the cathode, where reduction occurs. The electrons always flow from the anode to the cathode no matter what type of battery. 21.76 A D-sized alkaline battery is much larger than an AAA-sized one, so the D-sized battery contains greater amounts of the cell components. The cell potential is an intensive property and does not depend on the amounts of the cell components. The total charge, however, depends on the amount of cell components, so the D-sized battery produces more charge than the AAA-sized battery. 21.78 The Teflon spacers keep the two metals separated so that the copper cannot conduct electrons that would promote the corrosion (rusting) of the iron skeleton. 21.81 Sacrificial anodes are made of metals with $E^{\circ}$ less than that of iron, -0.44 V , so they are more easily oxidized than iron. Only (b), (f), and (g) will work for iron;
(a) will form an oxide coating that prevents further oxidation;
(c) would react with groundwater quickly; (d) and (e) are less easily oxidized than iron. 21.83 To reverse the reaction requires 0.34 V with the cell in its standard state. A 1.5 V cell supplies more than enough potential, so the cadmium metal is oxidized to $\mathrm{Cd}^{2+}$ and chromium plates out. 21.85 The oxidation number of N in $\mathrm{NO}_{3}{ }^{-}$is +5 , the maximum O.N. for N . In the nitrite ion, $\mathrm{NO}_{2}{ }^{-}$, the O.N. of N is +3 , so nitrogen can be further oxidized. 21.87(a) $\mathrm{Br}_{2}$ (b) $\mathrm{Na} \quad 21.89 \mathrm{I}_{2}$ gas forms at the anode; magnesium (liquid) forms at the cathode. 21.91 Bromine gas forms at
the anode; calcium metal forms at the cathode. 21.93 copper and bromine 21.95 iodine, zinc, and silver
21.97(a) Anode: $2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow \mathrm{O}_{2}(g)+4 \mathrm{H}^{+}(a q)+4 \mathrm{e}^{-}$ Cathode: $2 \mathrm{H}_{2} \mathrm{O}(l)+2 \mathrm{e}^{-} \longrightarrow \mathrm{H}_{2}(g)+2 \mathrm{OH}^{-}(a q)$

$21.1030 .275 \mathrm{~g} \mathrm{Ra} \quad 21.1059 .20 \times 10^{3} \mathrm{~s} \quad 21.107$ (a) The sodium and sulfate ions make the water conductive so that current will flow through the water, facilitating electrolysis. Pure water, which contains very low $\left(10^{-7} \mathrm{M}\right)$ concentrations of $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$, conducts electricity very poorly. (b) The reduction of $\mathrm{H}_{2} \mathrm{O}$ has a more positive half-potential than does the reduction of $\mathrm{Na}^{+}$; the oxidation of $\mathrm{H}_{2} \mathrm{O}$ is the only reaction possible because $\mathrm{SO}_{4}{ }^{2-}$ cannot be oxidized. Thus, it is easier to reduce $\mathrm{H}_{2} \mathrm{O}$ than $\mathrm{Na}^{+}$and easier to oxidize $\mathrm{H}_{2} \mathrm{O}$ than $\mathrm{SO}_{4}{ }^{2-} . \quad 21.10962 .6 \mathrm{~g} \mathrm{Zn}$
21.111(a) $3.3 \times 10^{11} \mathrm{C}$
(b) $4.8 \times 10^{11} \mathrm{~J}$
(c) $1.2 \times 10^{4} \mathrm{~kg}$
21.11464 .3 mass $\% \mathrm{Cu} \quad$ 21.116(a) 8 days $\quad$ (b) 32 days
$\begin{array}{llll}\text { (c) } \$ 250 \quad 21.119 & \text { (a) } 2.4 \times 10^{4} \text { days } & \text { (b) } 2.1 \mathrm{~g} & \text { (c) } 3.4 \times 10^{-5}\end{array}$ dollars 21.122(a) $\mathrm{Pb} / \mathrm{Pb}^{2+}: E_{\text {cell }}^{\circ}=0.13 \mathrm{~V} ; \mathrm{Cu} / \mathrm{Cu}^{2+}: E_{\text {cell }}^{\circ}=$ 0.34 V (b) The anode (negative electrode) is Pb . The anode in the other cell is platinum in the standard hydrogen electrode.
(c) The precipitation of PbS decreases $\left[\mathrm{Pb}^{2+}\right]$, which increases the potential. (d) -0.13 V 21.125 The three steps equivalent Ftothe eyeratreaction $\mathrm{M}^{+}(a q)+\mathrm{e}^{-} \longrightarrow \mathrm{M}(s)$ are

$$
\begin{array}{ll}
\text { (1) } \mathrm{M}^{+}(a q) \longrightarrow \mathrm{M}^{+}(g) & \Delta H \text { is }-\Delta H_{\text {hydration }} \\
\text { (2) } \mathrm{M}^{+}(g)+\mathrm{e}^{-} \longrightarrow \mathrm{M}(g) & \Delta H \text { is }-\mathrm{IE} \\
\text { (3) } \mathrm{M}(g) \longrightarrow \mathrm{M}(s) & \Delta H \text { is }-\Delta H_{\text {atomization }}
\end{array}
$$

The energy for step 3 is similar for all three elements, so the difference in energy for the overall reaction depends on the values for $\Delta H_{\text {hydration }}$ and IE. The $\mathrm{Li}^{+}$ion has a much greater hydration energy than $\mathrm{Na}^{+}$and $\mathrm{K}^{+}$because it is smaller, with large charge density that holds the water molecules more tightly. The energy required to remove the waters surrounding the $\mathrm{Li}^{+}$offsets the lower ionization energy, making the overall energy for the reduction of lithium larger than expected. 21.127 The very high and very low standard electrode potentials involve extremely reactive substances, such as $\mathrm{F}_{2}$ (a powerful oxidizer) and Li (a powerful reducer). These substances react directly with water because any aqueous cell with a voltage of more than 1.23 V has the ability to electrolyze water into hydrogen and oxygen.
21.129(a) $1.073 \times 10^{5} \mathrm{~s}$
(b) $1.5 \times 10^{4} \mathrm{~kW} \cdot \mathrm{~h}$
(c) $6.8 \propto$
$21.131 \mathrm{~F}<\mathrm{D}<\mathrm{E}$. If metal E and a salt of metal F are mixed, the salt is reduced, producing metal F because E has the greatest reducing strength of the three metals.
21.134(a) Cell I: 4 mol electrons; $\Delta G=-4.75 \times 10^{5} \mathrm{~J}$

Cell II: 2 mol electrons; $\Delta G=-3.94 \times 10^{5} \mathrm{~J}$
Cell III: 2 mol electrons; $\Delta G=-4.53 \times 10^{5} \mathrm{~J}$
(b) Cell I: $-13.2 \mathrm{~kJ} / \mathrm{g}$

Cell II: $-0.613 \mathrm{~kJ} / \mathrm{g}$
Cell III: $-2.62 \mathrm{~kJ} / \mathrm{g}$
Cell I has the highest ratio (most energy released per gram) because the reactants have very low mass, while Cell II has the lowest ratio because the reactants have large masses.

## Chapter 22

22.2 Fe from $\mathrm{Fe}_{2} \mathrm{O}_{3} ; \mathrm{Ca}$ from $\mathrm{CaCO}_{3} ; \mathrm{Na}$ from $\mathrm{NaCl} ; \mathrm{Zn}$ from ZnS 22.3(a) Differentiation refers to the processes involved in the formation of Earth into regions (core, mantle, and crust) of differing composition. Substances separated according to their densities, with the more dense material in the core and the less dense in the crust. (b) $\mathrm{O}, \mathrm{Si}, \mathrm{Al}$, and Fe (c) O 22.7 Plants produced $\mathrm{O}_{2}$, slowly increasing the oxygen concentration in the atmosphere and creating an oxidative environment for metals. The oxygen-free decay of plant and animal material created large fossil fuel deposits. 22.9 Fixation refers to the process of converting a substance in the atmosphere into a form more readily usable by organisms. Carbon and nitrogen; fixation of carbon dioxide gas by plants and fixation of nitrogen gas by nitrogenfixing bacteria. 22.12 Atmospheric nitrogen is fixed by three pathways: atmospheric, industrial, and biological. Atmospheric fixation requires high-temperature reactions (e.g., initiated by lightning) to convert $\mathrm{N}_{2}$ into NO and other oxidized species. Industrial fixation involves mainly the formation of ammonia, $\mathrm{NH}_{3}$, from $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$. Biological fixation occurs in nitrogenfixing bacteria that live on the roots of legumes. Human activity is an example of industrial fixation. It contributes about $17 \%$ of the nitrogen fixed. 22.14(a) the atmosphere (b) Plants excrete acid from their roots to convert $\mathrm{PO}_{4}{ }^{3-}$ ions into more soluble
$\mathrm{H}_{2} \mathrm{PO}_{4}^{-}$ions, which the plant can absorb. Through excretion and decay, organisms return soluble phosphate compounds to the cycle. $\quad 22.17$ (a) $1.1 \times 10^{3} \mathrm{~L}$ (b) $4.2 \times 10^{2} \mathrm{~m}^{3} \quad$ 22.18(a) The iron ions form an insoluble salt, $\mathrm{Fe}_{3}\left(\mathrm{PO}_{4}\right)_{2}$, that decreases the yield of phosphorus. (b) $8.8 \mathrm{t} \quad$ 22.20(a) Roasting involves heating the mineral in air at high temperatures to convert the mineral to the oxide. (b) Smelting is the reduction of the metal oxide to the free metal using heat and a reducing agent such as coke. (c) Flotation is a separation process in which the ore is removed from the gangue by exploiting the difference in density in the presence of detergent. The gangue sinks to the bottom and the lighter ore-detergent mix is skimmed off the top. (d) Refining is the final step in the purification process to yield the pure metal. 22.25(a) Slag is a byproduct of steel-making and contains the impurity $\mathrm{SiO}_{2}$. (b) Pig iron is the impure product of iron metallurgy (containing 3-4\% C and other impurities). (c) Steel refers to iron alloyed with other elements to attain desirable properties. (d) The basic-oxygen process is used to purify pig iron and obtain carbon steel. 22.27 Iron and nickel are more easily oxidized and less easily reduced than copper. They are separated from copper in the roasting step and converted to slag. In the electrorefining process, all three metals are in solution, but only $\mathrm{Cu}^{2+}$ ions are reduced at the cathode to form $\mathrm{Cu}(s)$.
22.30 Le Châtelier's principle says that the system shifts toward formation of K as the gaseous metal leaves the cell.
22.31 (a) $E_{\text {half-cell }}^{\circ}=-3.05 \mathrm{~V},-2.93 \mathrm{~V}$, and -2.71 V for $\mathrm{Li}^{+}$, $\mathrm{K}^{+}$, and $\mathrm{Na}^{+}$, respectively. In all of these cases, it is energetically more favorable to reduce $\mathrm{H}_{2} \mathrm{O}$ to $\mathrm{H}_{2}$ than to reduce $\mathrm{M}^{+}$to M . (b) $2 \mathrm{RbX}+\mathrm{Ca} \longrightarrow \mathrm{CaX} 2+2 \mathrm{Rb}$, where $\Delta H=\mathrm{IE}_{1}(\mathrm{Ca})+$
 tive $\Delta \vec{H}$ for the forward reaction, it seems more reasonable that Rb metal will reduce $\mathrm{Ca}^{2+}$ than the reverse. (c) If the reaction is carried out at a temperature greater than the boiling point of Rb , the product mixture will contain gaseous Rb , which can be removed from the reaction vessel; this would cause a shift in equilibrium to form more Rb as product. $\quad$ (d) $2 \mathrm{CsX}+\mathrm{Ca} \longrightarrow$ $\mathrm{CaX} 2+2 \mathrm{Cs}$, where $\Delta H=\mathrm{IE}_{1}(\mathrm{Ca})+\mathrm{IE}_{2}(\mathrm{Ca})-2 \mathrm{IE}_{1}(\mathrm{Cs})=$ $983 \mathrm{~kJ} / \mathrm{mol}$. This reaction is more unfavorable than for Rb , but Cs has a lower boiling point. $\quad 22.32$ (a) $4.5 \times 10^{4} \mathrm{~L}$ $\begin{array}{lll}\text { (b) } 1.30 \times 10^{8} \mathrm{C} & \text { (c) } 1.69 \times 10^{6} \mathrm{~s} & 22.35(\mathrm{a}) \mathrm{Mg}^{2+} \text { is more diffi- }\end{array}$ cult to reduce than $\mathrm{H}_{2} \mathrm{O}$, so $\mathrm{H}_{2}(\mathrm{~g})$ would be produced instead of Mg metal. $\mathrm{Cl}_{2}(g)$ forms at the anode due to overvoltage.
(b) The $\Delta H_{\mathrm{f}}^{\circ}$ of $\mathrm{MgCl}_{2}(s)$ is $-641.6 \mathrm{~kJ} / \mathrm{mol}$. High temperature favors the reverse (endothermic) reaction, the formation of magnesium metal and chlorine gas. 22.37(a) Sulfur dioxide is the reducing agent and is oxidized to the +6 state $\left(\mathrm{SO}_{4}{ }^{2-}\right)$.
(b) $\mathrm{HSO}_{4}^{-}(a q)$ (c) $\mathrm{H}_{2} \mathrm{SeO}_{3}(a q)+2 \mathrm{SO}_{2}(g)+\mathrm{H}_{2} \mathrm{O}(l) \longrightarrow$ $\mathrm{Se}(s)+2 \mathrm{HSO}_{4}^{-}(a q)+2 \mathrm{H}^{+}(a q) \quad$ 22.42(a) O.N. for Cu : in $\mathrm{Cu}_{2} \mathrm{~S},+1$; in $\mathrm{Cu}_{2} \mathrm{O},+1$; in $\mathrm{Cu}, 0 \quad$ (b) $\mathrm{Cu}_{2} \mathrm{~S}$ is the reducing agent, and $\mathrm{Cu}_{2} \mathrm{O}$ is the oxidizing agent. $\quad 22.44$ (a) $1.3 \times 10^{6} \mathrm{C}$ (b) $1.2 \times 10^{3} \mathrm{~A} \quad 22.472 \mathrm{ZnS}(s)+\mathrm{C}$ (graphite) $\longrightarrow 2 \mathrm{Zn}(s)+$ $\mathrm{CS}_{2}(g) ; \Delta G_{\mathrm{rxn}}^{\circ}=463 \mathrm{~kJ}$. Since $\Delta G_{\mathrm{rxn}}^{\circ}$ is positive, this reaction is not spontaneous at standard-state conditions. $2 \mathrm{ZnO}(s)+\mathrm{C}(s) \longrightarrow$ $2 \mathrm{Zn}(s)+\mathrm{CO}_{2}(\mathrm{~g}) ; \Delta G_{\mathrm{rxn}}^{\circ}=242.0 \mathrm{~kJ}$. This reaction is also not spontaneous, but is less unfavorable. 22.48 The formation of sulfur trioxide is very slow at ordinary temperatures. Increasing the temperature can speed up the reaction, but because the reaction is exothermic, increasing the temperature decreases the yield. Adding a catalyst increases the rate of the reaction, so a lower temperature can be used to enhance the yield.
22.51(a) $\mathrm{Cl}_{2}, \mathrm{H}_{2}$, and NaOH (b) The mercury-cell process yields higher purity NaOH , but releases some Hg , which is discharged into the environment. 22.52(a) $\Delta G^{\circ}=-142 \mathrm{~kJ}$; yes (b) The rate of the reaction is very slow at $25^{\circ} \mathrm{C}$. (c) $\Delta G_{500}^{\circ}=$ -53 kJ , so the reaction is spontaneous. (d) $K_{25}=7.8 \times 10^{24}>$ $K_{500}=3.8 \times 10^{3} \quad$ (e) $1.05 \times 10^{3} \mathrm{~K} \quad 22.537 \times 10^{2} \mathrm{lb} \mathrm{Cl}_{2}$ 22.57(a) $\mathrm{P}_{4} \mathrm{O}_{10}(s)+6 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 4 \mathrm{H}_{3} \mathrm{PO}_{4}(l) \quad$ (b) 1.52 22.59(a) $9.006 \times 10^{9} \mathrm{~g} \mathrm{CO}_{2}$ (b) The $4.3 \times 10^{10} \mathrm{~g} \mathrm{CO}_{2}$ produced by automobiles is much greater than that from the blast furnace. 22.61(a) If $\left[\mathrm{OH}^{-}\right]>1.1 \times 10^{-4} M$ (i.e., if $\mathrm{pH}>10.04$ ),
$\mathrm{Mg}(\mathrm{OH})_{2}$ will precipitate. (b) 1 (To the correct number of significant figures, all the magnesium has precipitated.)

## Chapter 23

23.2(a) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{10} 4 p^{6} 5 s^{2} 4 d^{x}$
(b) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{10} 4 p^{6} 5 s^{2} 4 d^{10} 5 p^{6} 6 s^{2} 4 f^{14} 5 d^{x} \quad 23.4$ Five; examples are $\mathrm{Mn},[\mathrm{Ar}] 4 s^{2} 3 d^{5}$, and $\mathrm{Fe}^{3+},[\mathrm{Ar}] 3 d^{5}$. 23.6(a) The elements should increase in size as they increase in mass from
Period 5 to Period 6. Because 14 additional elements lie between Periods 5 and 6, the effective nuclear charge increases significantly; so the atomic size decreases, or "contracts." This effect is significant enough that $\mathrm{Zr}^{4+}$ and $\mathrm{Hf}^{4+}$ are almost the same size but differ greatly in atomic mass. (b) The atomic size increases from Period 4 to Period 5, but stays fairly constant from Period 5 to Period 6. (c) Atomic mass increases significantly from Period 5 to Period 6, but atomic radius (and thus volume) increases slightly, so Period 6 elements are very dense. 23.9(a) A paramagnetic substance is attracted to a magnetic field, while a diamagnetic substance is slightly repelled by one. (b) Ions of transition elements often have half-filled $d$ orbitals whose unpaired electrons make the ions paramagnetic. Ions of main-group
elements usually have a noble-gas configuration with no partially filled levels. (c) Some $d$ orbitals in the transition element ions are empty, which allows an electron from one $d$ orbital to move to a slightly higher energy one. The energy required for this transition is small and falls in the visible wavelength range. All orbitals are filled in ions of main-group elements, so enough energy would have to be added to move an electron to the next principal energy level, not just another orbital within the same energy level. This amount of energy is very large and much greater than the visible range of wavelengths.
23.10(a) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{3}$
(b) $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{2} 3 d^{10} 4 p^{6} 5 s^{2} 4 d^{1} \quad$ (c) $[\mathrm{Xe}] 6 s^{2} 4 f^{14} 5 d^{10}$
23.12(a) [Xe] $6 s^{2} 4 f^{14} 5 d^{6}$ (b) $[\mathrm{Ar}] 4 s^{2} 3 d^{7} \quad$ (c) $[\mathrm{Kr}] 5 s^{1} 4 d^{10}$ 23.14(a) [Ar], no unpaired electrons (b) [Ar] $3 d^{9}$, one unpaired electron (c) $[\mathrm{Ar}] 3 d^{5}$, five unpaired electrons (d) $[\mathrm{Kr}] 4 d^{2}$, two unpaired electrons $\quad 23.16($ a) +5 (b) $+4 \quad$ (c) +7 23.18 Cr , Mo , and W 23.20 $\mathrm{In}_{\mathrm{CrF}}^{2}$, because the chromium is in a lower oxidation state. 23.22 Atomic size increases slightly down a group of transition elements, but nuclear charge increases much more, so the first ionization energy generally increases. The reduction potential for Mo is lower, so it is more difficult to oxidize Mo than Cr. In addition, the ionization energy of Mo is higher than that of Cr , so it is more difficult to remove electrons from Mo. $\quad 23.24 \mathrm{CrO}_{3}$, with Cr in a higher oxidation state, yields a more acidic aqueous solution. 23.28(a) seven (b) This corresponds to a half-filled $f$ subshell. $\quad$ 23.30(a) $[\mathrm{Xe}] 6 s^{2} 5 d^{1}$ $\begin{array}{llll}\text { (b) }[\mathrm{Xe}] 4 f^{1} & \text { (c) }[\mathrm{Rn}] 7 s^{2} 5 f^{11} & \text { (d) }[\mathrm{Rn}] 5 f^{2} & 23.32(\mathrm{a}) \mathrm{Eu}^{2+} \text { : }\end{array}$ $[\mathrm{Xe}] 4 f^{7} ; \mathrm{Eu}^{3+}$ : $[\mathrm{Xe}] 4 f^{6} ; \mathrm{Eu}^{4+}$ : [Xe] $4 f^{5}$. The stability of the half-filled $f$ subshell makes $\mathrm{Eu}^{2+}$ most stable. (b) $\mathrm{Tb}^{2+}$ :
ErXeh $4 \epsilon^{9} ; \mathrm{Tb}^{3+} \mathrm{C}^{+}[\mathrm{Xe}] 4 f^{8} ; \mathrm{Tb}^{4+}$ : [Xe] $4 f^{7}$. Tb should show $\mathrm{a}+4$ oxidation state because that gives the half-filled subshell.
23.34 Gd has the electron configuration $[\mathrm{Xe}] 6 s^{2} 4 f^{7} 5 d^{1}$ with eight unpaired electrons. $\mathrm{Gd}^{3+}$ has seven unpaired electrons: [Xe] $4 f^{7}$. 23.36 Valence-state electronegativity is the apparent electronegativity of an element in a given oxidation state. As Mn is bonded to more O atoms in its different oxides, its O.N. becomes more positive. In solution, an $\mathrm{H}_{2} \mathrm{O}$ molecule is attracted to the increasingly positive Mn , and one of its protons becomes easier to lose. 23.40 Mercury exists in the liquid state at room temperature due to relatively few and relatively weak interactions among Hg atoms. Mercury occurs in the +1 oxidation state, unusual for its group, because two mercury $1+$ ions form a dimer, $\mathrm{Hg}_{2}{ }^{2+}$, by sharing their unpaired $6 s$ electrons in a covalent bond. $23.422 \mathrm{Cr}^{3+}(a q)+\mathrm{Cr}(s) \longrightarrow 3 \mathrm{Cr}^{2+} ; E^{\circ}=+0.50 \mathrm{~V}$; yes, the reaction is spontaneous. $\quad 23.443 \mathrm{Mn}^{2+}(a q)+2 \mathrm{MnO}_{4}{ }^{-}(a q)+$ $2 \mathrm{H}_{2} \mathrm{O}(l) \longrightarrow 5 \mathrm{MnO}_{2}(s)+4 \mathrm{H}^{+}(a q) ; E^{\circ}=+0.28 \mathrm{~V}$; the reaction is spontaneous, so the $\mathrm{Mn}^{2+}$ will react with remaining $\mathrm{MnO}_{4}{ }^{-}$to form $\mathrm{MnO}_{2}$. 23.47 The coordination number indicates the number of ligand atoms bonded to the metal ion. The oxidation number represents the number of electrons lost to form the ion. The coordination number is unrelated to the oxidation number. 23.49 2, linear; 4 , tetrahedral or square planar; 6 , octahedral 23.52 The complex ion has a negative charge. 23.55(a) hexaaquanickel(II) chloride
(b) tris(ethylenediamine) chromium(III) perchlorate
(c) potassium hexacyanomanganate(II) 23.57(a) $2+, 6$

23.77 The compound with the traditional formula is $\mathrm{CrCl}_{3} \cdot 4 \mathrm{NH}_{3}$; the actual formula is $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}$. 23.79(a) $\mathrm{K}\left[\mathrm{Pd}\left(\mathrm{NH}_{3}\right) \mathrm{Cl}_{3}\right]$
(b) $\left[\mathrm{PdCl}_{2}\left(\mathrm{NH}_{3}\right)_{2}\right]$
(c) $\mathrm{K}_{2}\left[\mathrm{PdCl}_{6}\right]$
(d) $\left[\mathrm{Pd}\left(\mathrm{NH}_{3}\right)_{4} \mathrm{Cl}_{2}\right] \mathrm{Cl}_{2}$
23.81(a) $d s p^{2}$ (b) $s p^{3} \quad 23.84$ absorption of orange or yellow light 23.85(a) The crystal field splitting energy ( $\Delta$ ) is the energy difference between the two sets of $d$ orbitals that result from the bonding of ligands to a central transition metal atom. (b) In an octahedral field of ligands, the ligands approach along the $x$, $y$, and $z$ axes. The $d_{x^{2}-y^{2}}$ and $d_{z^{2}}$ orbitals are located along the $x$, $y$, and $z$ axes, so ligand interaction is higher in energy. The other orbital-ligand interactions are lower in energy because the $d_{x y}$, $d_{y z}$, and $d_{x z}$ orbitals are located between the $x, y$, and $z$ axes. (c) In a tetrahedral field of ligands, the ligands do not approach along the $x, y$, and $z$ axes. The ligand interaction is greater for the $d_{x y}, d_{y z}$, and $d_{x z}$ orbitals and lesser for the $d_{x^{2}-y^{2}}$ and $d_{z^{2}}$ orbitals. Therefore, the crystal field splitting is reversed, and the $d_{x y}, d_{y z}$, and $d_{x z}$ orbitals are higher in energy than the $d_{x^{2}-y^{2}}$ and $d_{z^{2}}$ orbitals. 23.88 If $\Delta$ is greater than $E_{\text {pairing, }}$, electrons will pair their spins in the lower energy $d$ orbitals before adding as unpaired electrons to the higher energy $d$ orbitals. If $\Delta$ is less than $E_{\text {pairing }}$, electrons will add as unpaired electrons to the higher energy $d$ orbitals before pairing in the lower energy $d$ orbitals.
23.90(a) no $d$ electrons
(b) eight $d$ electrons
(c) $\operatorname{six} d$ electrons
23.92(a) five
(b) ten
(c) seven
23.94

In an octahedral field of ligands, the ligands approach along the $x, y$, and $z$ axes. The $d_{x^{2}-y^{2}}$ orbital is located along the $x$ and $y$ axes, so ligand interaction is greater. The $d_{x y}$ orbital is offset from the $x$ and $y$ axes by $90^{\circ}$, so ligand interaction is less. The greater interaction of the $d_{x^{2}-y^{2}}$ orbital results in its higher energy. 23.96 (a) and (d)

23.104 A violet complex absorbs yellow-green light. The light absorbed by a complex with a weaker field ligand would be at a lower energy and higher wavelength. Light of lower energy than yellow-green light is yellow, orange, or red. The color observed would be blue or green. 23.107 The $\mathrm{H}_{2} \mathrm{O}$ ligand is weaker than
the $\mathrm{NH}_{3}$ ligand. The weaker field ligand results in a lower splitting energy and absorbs visible light of lower energy. The hexaaqua complex appears green because it absorbs red light. The hexaammine complex appears violet because it absorbs yellow light, which has higher energy (shorter $\lambda$ ) than red light. $23.111 \mathrm{Hg}^{+}$is [Xe] $6 s^{1} 4 f^{14} 5 d^{10}$ and $\mathrm{Cu}^{+}$is [ Ar$] 3 d^{10}$. The mercury $(\mathrm{I})$ ion has one electron in the $6 s$ orbital that can form a covalent bond with the electron in the $6 s$ orbital of another mercury(I) ion. In the copper(I) ion there are no electrons in the $s$ orbital, so these ions cannot bond with one another. 23.113(a) 6

23.140(a) The first reaction shows no change in the number of particles. In the second reaction, the number of reactant particles is greater than the number of product particles. A decrease in the number of particles means a decrease in entropy. Based on entropy change only, the first reaction is favored.
(b) The ethylenediamine complex will be more stable with respect to ligand exchange in water because the entropy change for that exchange is unfavorable.

## Chapter 24

24.1(a) Chemical reactions are accompanied by relatively small changes in energy; nuclear reactions are accompanied by relatively large changes in energy. (b) Increasing temperature increases the rate of a chemical reaction but has no effect on a nuclear reaction. (c) Both chemical and nuclear reaction rates increase with higher reactant concentrations. (d) If the reactant is limiting in a chemical reaction, then more reactant produces more product and the yield increases. The presence of more radioactive reactant results in more decay product, so a higher reactant concentration increases the yield. 24.2(a) $95.02 \%$ (b) The atomic mass is larger than the isotopic mass of ${ }^{32} \mathrm{~S}$. Sulfur-32 is the lightest isotope. 24.4(a) $Z$ down by $2, N$ down $\begin{array}{llll}\text { by } 2 & \text { (b) } Z \text { up by } 1, N \text { down by } 1 & \text { (c) no change in } Z \text { or } N & \text { (d) } Z\end{array}$ down by $1, N$ up by 1 (e) $Z$ down by $1, N$ up by 1 ; A different element is produced in all cases except c. 24.6 A neutron-rich nuclide decays by beta decay. A neutron-poor nuclide undergoes
positron decay or electron capture. 24.8(a) ${ }_{92}^{234} \mathrm{U} \longrightarrow{ }_{2}^{4} \alpha+$ ${ }_{90}^{230} \mathrm{Th} \quad$ (b) ${ }_{93}^{232} \mathrm{~Np}+{ }_{-1}^{0} \mathrm{e} \longrightarrow{ }_{92}^{232} \mathrm{U} \quad$ (c) ${ }_{7}^{12} \mathrm{~N} \longrightarrow{ }_{1}^{0} \beta+{ }_{6}^{12} \mathrm{C}$ 24.10(a) ${ }_{12}^{27} \mathrm{Mg} \longrightarrow{ }_{-1}^{0} \beta+{ }_{13}^{27} \mathrm{Al} \quad$ (b) ${ }_{12}^{23} \mathrm{Mg} \longrightarrow{ }_{1}^{0} \beta+{ }_{11}^{23} \mathrm{Na}$ (c) ${ }_{46}^{103} \mathrm{Pd}+{ }_{-1}^{0} \mathrm{e} \longrightarrow{ }_{45}^{103} \mathrm{Rh} \quad$ 24.12(a) ${ }_{23}^{48} \mathrm{~V} \longrightarrow{ }_{22}^{48} \mathrm{Ti}+{ }_{1}^{0} \beta$ (b) ${ }_{48}^{107} \mathrm{Cd}+{ }_{-1}^{0} \mathrm{e} \longrightarrow{ }_{47}^{107} \mathrm{Ag}$ (c) ${ }_{86}^{210} \mathrm{Rn} \longrightarrow{ }_{84}^{206} \mathrm{Po}+{ }_{2}^{4} \alpha$ 24.14(a) ${ }_{78}^{186} \mathrm{Pt}+{ }_{-1}^{0} \mathrm{e} \longrightarrow{ }_{77}^{186} \mathrm{Ir}$ (b) ${ }_{89}^{225} \mathrm{Ac} \longrightarrow{ }_{87}^{221} \mathrm{Fr}+{ }_{2}^{4} \alpha$ (c) ${ }_{52}^{129} \mathrm{Te} \longrightarrow{ }_{53}^{129} \mathrm{I}+{ }_{-1}^{0} \beta \quad$ 24.16(a) Appears stable because its $N$ and $Z$ values are both magic numbers, but its $N / Z$ ratio (1.50) is too high; it is unstable. (b) Appears unstable because its $Z$ value is an odd number, but its $N / Z$ ratio (1.19) is in the band of stability, so it is stable. (c) Unstable because its $N / Z$ ratio is too high. 24.18(a) The $N / Z$ ratio for ${ }^{127}$ I is 1.4 ; it is stable. (b) The $N / Z$ ratio for ${ }^{106} \mathrm{Sn}$ is 1.1 ; it is unstable because this ratio is too low. (c) The $N / Z$ ratio is 1.1 for ${ }^{68}$ As. The ratio is within the range of stability, but the nuclide is most likely unstable because there is an odd number of both protons and neutrons. 24.20(a) alpha decay (b) positron decay or electron capture (c) positron decay or electron capture 24.22(a) beta decay (b) positron decay or electron capture (c) alpha decay 24.24 Stability results from a favorable $N / Z$ ratio, even numbered $N$ and/or $Z$, and the occurrence of magic numbers. The $N / Z$ ratio of ${ }^{52} \mathrm{Cr}$ is 1.17 , which is within the band of stability. The fact that $Z$ is even does not account for the variation in stability because all isotopes of chromium have the same $Z$. However, ${ }^{52} \mathrm{Cr}$ has 28 neutrons, so $N$ is both an even number and a magic number for this isotope only. 24.28 seven $\alpha$ emissions and four $\beta^{-}$emissions 24.31 No, it is not valid to conclude that $t_{1 / 2}$ equals 1 min because the number of nuclei is so small. Decay rate is an average rate and is only meaningful when the sample is macroscopic and contains a large number of nuclei. For the sample containing $6 \times 10^{12}$ Anueleis thePD conclusion is valid. $\quad 24.332 .56 \times 10^{-2} \mathrm{Ci} / \mathrm{g} \quad 24.351 .4 \times 10^{8} \mathrm{~Bq} / \mathrm{g}$ $24.371 \times 10^{-12}$ day $^{-1} \quad 24.392 .31 \times 10^{-7} \mathrm{yr}^{-1} \quad 24.411 .49 \mathrm{mg}$ $24.432 .2 \times 10^{9}$ yr $\quad 24.4530 \mathrm{dpm} \quad 24.471 .0 \times 10^{6}$ yr
24.50 Both $\gamma$ radiation and neutron beams have no charge, but a neutron has a mass approximately equal to that of a proton. 24.52 Protons are repelled from the target nuclei due to interaction with like (positive) charges. Higher energy is required to overcome the repulsion. 24.53(a) ${ }_{5}^{10} \mathrm{~B}+{ }_{2}^{4} \alpha \longrightarrow{ }_{0}^{1} \mathrm{n}+{ }_{7}^{13} \mathrm{~N}$ (b) ${ }_{14}^{28} \mathrm{Si}+{ }_{1}^{2} \mathrm{H} \longrightarrow{ }_{0}^{1} \mathrm{n}+{ }_{15}^{29} \mathrm{P}$
(c) ${ }_{96}^{242} \mathrm{Cm}+{ }_{2}^{4} \alpha \longrightarrow 2{ }_{0}^{1} \mathrm{n}+{ }_{98}^{244} \mathrm{Cf} \quad 24.58$ Ionizing radiation is more dangerous to children because their rapidly dividing cells are more susceptible to radiation than adults' slowly dividing cells. $\quad 24.60$ (a) $5.4 \times 10^{-7} \mathrm{rad}$ (b) $5.4 \times 10^{-9} \mathrm{~Gy}$ 24.62(a) $7.5 \times 10^{-10}$ Gy $\quad$ (b) $7.5 \times 10^{-5} \mathrm{mrem} \quad$ (c) $7.5 \times 10^{-10} \mathrm{~Sv}$ $24.651 .86 \times 10^{-3} \mathrm{rad} \quad 24.67$ NAA does not destroy the sample, while chemical analyses do. Neutrons bombard a nonradioactive sample, inducing some atoms within the sample to be radioactive. The radioisotopes decay by emitting radiation characteristic
of each isotope. 24.73 Energy is released when a nuclide forms from nucleons. The nuclear binding energy is the amount of energy holding the nucleus together. This energy must be absorbed to break up the nucleus into nucleons and is released when nucleons come together. $\quad 24.75$ (a) $1.861 \times 10^{4} \mathrm{eV} \quad$ (b) $2.981 \times 10^{15} \mathrm{~J}$ $24.777 .6 \times 10^{11} \mathrm{~J} \quad 24.79$ (a) $7.976 \mathrm{MeV} /$ nucleon $\quad$ (b) 127.6 $\mathrm{MeV} / \mathrm{atom} \quad$ (c) $1.231 \times 10^{10} \mathrm{~kJ} / \mathrm{mol} \quad 24.81$ (a) $8.768 \mathrm{MeV} /$ nucleon (b) $517.3 \mathrm{MeV} / \mathrm{atom}$ (c) $4.99 \times 10^{10} \mathrm{~kJ} / \mathrm{mol}$ 24.85 Radioactive decay is a spontaneous process in which unstable nuclei emit radioactive particles and energy. Fission occurs as the result of high-energy bombardment of nuclei with small particles that cause the nuclei to break into smaller nuclides, radioactive particles, and energy. All fission events are not the same. The nuclei split in a number of ways to produce several different products. 24.88 The water serves to slow the neutrons so that they are better able to cause a fission reaction. Heavy water is a better moderator because it does not absorb neutrons as well as light water does; thus, more neutrons are available to initiate the fission process. However, $\mathrm{D}_{2} \mathrm{O}$ does not occur naturally in great abundance, so its production adds to the cost of a heavy-water reactor. 24.91 In the $s$-process, a nucleus captures a neutron, emitting a $\gamma$ ray. Then the nucleus emits a $\beta$ particle to form another element. The stable isotopes of most heavy elements form by the $s$-process. The $r$-process forms less stable isotopes by multiple neutron captures, followed by multiple $\beta$ decays. $\quad 24.95$ (a) $1.1 \times 10^{-29} \mathrm{~kg}$ (b) $9.8 \times 10^{-13} \mathrm{~J}$ (c) $5.9 \times 10^{8} \mathrm{~kJ} / \mathrm{mol}$. This is approximately 1 million times larger than a typical heat of reaction. $24.978 .0 \times 10^{3} \mathrm{yr}$ $24.1011 .35 \times 10^{-5} M \quad 24.1036 .2 \times 10^{-2} \quad 24.106($ a) 5.99 h

## GLOSSARY

Numbers in parentheses refer to the page(s) on which a term is introduced and/or discussed.

## A

absolute scale (also Kelvin scale) The preferred temperature scale in scientific work, which has absolute zero ( 0 K , or $-273.15^{\circ} \mathrm{C}$ ) as the lowest temperature. (25) [See also kelvin ( $K$ ).] absorption spectrum The spectrum produced when atoms absorb specific wavelengths of incoming light and become excited from lower to higher energy levels. (281)
abundance The amount of an element in a particular region of the natural world. (981)
accuracy The closeness of a measurement to the actual value. (31)
acid In common laboratory terms, any species that produces $\mathrm{H}^{+}$ ions when dissolved in water. (150) [See also Brønsted-Lowry, classical (Arrhenius), and Lewis acid-base definitions.]
acid anhydride A compound, sometimes formed by a dehydration-condensation reaction of an oxoacid, that yields two molecules of the acid when it reacts with water. (658)
acid-base buffer (also buffer) A solution that resists changes in pH when a small amount of either strong acid or strong base is added. (832)
acid-base indicator A species whose color is different in acid and in base, which is used to monitor the equivarente point of a titration or the pH of a solution. $(154,793,842)$
acid-base reaction Any reaction between an acid and a base. (150) (See also neutralization reaction.)
acid-base titration curve A plot of the pH of a solution of acid (or base) versus the volume of base (or acid) added to the solution. (841)
acid-dissociation (acid-ionization) constant ( $K_{\mathrm{a}}$ ) An equilibrium constant for the dissociation of an acid (HA) in $\mathrm{H}_{2} \mathrm{O}$ to yield the conjugate base $\left(\mathrm{A}^{-}\right)$and $\mathrm{H}_{3} \mathrm{O}^{+}$:

$$
\begin{equation*}
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[A^{-}\right]}{[\mathrm{HA}]} \tag{786}
\end{equation*}
$$

actinides The Period 7 elements that constitute the second inner transition series ( $5 f$ block), which includes thorium (Th; $Z=90$ ) through lawrencium ( $\mathrm{Lr} ; Z=103$ ). $(316,1030)$
activated complex (See transition state.)
activation energy ( $E_{\mathrm{a}}$ ) The minimum energy with which molecules must collide to react. (706)
active site The region of an enzyme formed by specific amino acid side chains at which catalysis occurs. (723)
activity $(\mathscr{A})$ (also decay rate) The change in number of nuclei $(\mathcal{N})$ of a radioactive sample divided by the change in time $(t)$. (1074)
activity series of the metals A listing of metals arranged in order of decreasing strength of the metal as a reducing agent in aqueous reactions. (171)
actual yield The amount of product actually obtained in a chemical reaction. (118)
addition polymer (also chain-reaction, or chain-growth, polymer) A polymer formed when monomers (usually containing $\mathrm{C}=\mathrm{C}$ ) combine through an addition reaction. (663)
addition reaction A type of organic reaction in which atoms linked by a multiple bond become bonded to more atoms. (647)
adduct The product of a Lewis acid-base reaction characterized by the formation of a new covalent bond. (817)
adenosine triphosphate (ATP) A high-energy molecule that serves most commonly as a store and source of energy in organisms. (908)
alchemy An occult study of nature that flourished for 1500 years in northern Africa and Europe and resulted in the development of several key laboratory methods. (10)
alcohol An organic compound (ending, ool) that contains a

aldehyde An organic compound (ending, -al) that contains the carbonyl functional group $(\mathrm{C}=\ddot{\mathrm{O}})$ in which the carbonyl C is also bonded to H . (655)
alkane A hydrocarbon that contains only single bonds (general formula, $\mathrm{C}_{n} \mathrm{H}_{2 n+2}$ ). (635)
alkene A hydrocarbon that contains at least one $\mathrm{C}=\mathrm{C}$ bond $\mathrm{F}_{\mathrm{c}}$ (general formula, $\mathrm{C}_{n} \mathrm{H}_{2 n}$ ). (640)
alkyl group A saturated hydrocarbon chain with one bond available. (646)
alkyl halide (See haloalkane.)
alkyne A hydrocarbon that contains at least one $\mathrm{C} \equiv \mathrm{C}$ bond (general formula, $\mathrm{C}_{n} \mathrm{H}_{2 n-2}$ ). (643)
allotrope One of two or more crystalline or molecular forms of an element. In general, one allotrope is more stable than another at a particular pressure and temperature. (585)
alloy A mixture with metallic properties that consists of solid phases of two or more pure elements, a solid-solid solution, or distinct intermediate phases. $(369,506,997)$
alpha ( $\alpha$ ) decay A radioactive process in which an alpha particle is emitted from a nucleus. (1069)
alpha particle ( $\alpha$ or ${ }_{2}^{4} \mathrm{He}$ ) A positively charged particle, identical to a helium nucleus, that is one of the common types of radioactive emissions. (1067)
amide An organic compound that contains the $-\stackrel{\|}{\mathrm{C}}-\mathrm{N}-$ functional group. (657)
amine An organic compound (general formula, $-\underset{\mid}{\mathrm{C}}-\underset{\mathrm{N}}{ }-$ )
derived structurally by replacing one or more H atoms of ammonia with alkyl groups; a weak organic base. $(652,806)$
amino acid An organic compound [general formula, $\left.\mathrm{H}_{2} \mathrm{~N}-\mathrm{CH}(\mathrm{R})-\mathrm{COOH}\right]$ with at least one carboxyl and one amine group on the same molecule; the monomer unit of a protein. $(507,667)$
amorphous solid A solid that occurs in different shapes because it lacks extensive molecular-level ordering of its particles. (463)
ampere (A) The SI unit of electric current; 1 ampere of current results when 1 coulomb flows through a conductor in 1 second. (965)
amphoteric Able to act as either an acid or a base. (327)
amplitude The height of the crest (or depth of the trough) of a wave; related to the intensity of the energy. (270)
angular momentum quantum number ( $l$ ) (also orbital-shape quantum number) An integer from 0 to $n-1$ that is related to the shape of an atomic orbital. (289)
anion A negatively charged ion. (60)
anode The electrode at which oxidation occurs in an electrochemical cell. Electrons are given up by the reducing agent and leave the cell at the anode. (929)
antibonding MO A molecular orbital formed when wave functions are subtracted from each other, which decreases electron density between the nuclei and leaves a node. Electrons occupying such an orbital destabilize the molecule. (422)
apatite A compound of general formula $\mathrm{Ca}_{5}\left(\mathrm{PO}_{4}\right)_{3} \mathrm{X}$, where X is generally $\mathrm{F}, \mathrm{Cl}$, or OH . (990)
aqueous solution A solution in which water is the solvent. (75)
aromatic hydrocarbon A compound of C and H with one or more rings of C atoms (often drawn with alternating $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}=\mathrm{C}$ bonds), in which there is extensive delocalization of $\pi$ electrons. (644)
Arrhenius acid-base definition [See classical (Arrhenius) acid-base definition.]
Arrhenius equation An equation that expresses the exponential relationship between temperature and the rate constant: $k=A e^{-E_{\mathrm{a}} / R T}$. (706)
atmosphere The mixture of gases that Zextends fromPa planet's surface and eventually merges with outer space; the gaseous portion of Earth's crust. $(218,983)$ (For the unit, see standard atmosphere.)
atom The smallest particle of an element that retains the chemical nature of the element. A neutral, spherical entity composed of a positively charged central nucleus surrounded by one or more negatively charged electrons. (47)
atomic mass (also atomic weight) The average of the masses of the naturally occurring isotopes of an element weighted according to their abundances. (54)
atomic mass unit (amu) (also dalton, $D a$ ) A mass exactly equal to $\frac{1}{12}$ the mass of a carbon-12 atom. (54)
atomic number ( $Z$ ) The unique number of protons in the nucleus of each atom of an element (equal to the number of electrons in the neutral atom). An integer that expresses the positive charge of a nucleus in multiples of the electronic charge. (53)
atomic orbital (also wave function) A mathematical expression that describes the motion of the electron's matter-wave in terms of time and position in the region of the nucleus. The term is used qualitatively to mean the region of space in which there is a high probability of finding the electron. (287)
atomic size A term referring to the atomic radius, one-half the distance between nuclei of identical bonded elements. $(317,555)$ (See also covalent radius and metallic radius.)
atomic solid A solid consisting of individual atoms held together by dispersion forces; the frozen noble gases are the only examples. (470)
atomic symbol (also element symbol) A one- or two-letter abbreviation for the English, Latin, or Greek name of an element. (53)
aufbau principle The conceptual basis of a process of building up atoms by adding one proton (and one or more neutrons) at a time to the nucleus and one electron around it to obtain the ground-state electron configurations of the elements. (308)
autoionization (also self-ionization) A reaction in which two molecules of a substance react to give ions. The most important example is for water:

$$
\begin{equation*}
2 \mathrm{H}_{2} \mathrm{O}(l) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{OH}^{-}(a q) \tag{789}
\end{equation*}
$$

average rate The change in concentration of reactants (or products) divided by a finite time period. (688)
Avogadro's law The gas law stating that, at fixed temperature and pressure, equal volumes of any ideal gas contain equal numbers of particles, and, therefore, the volume of a gas is directly proportional to its amount (mol): $V \propto n$. (197)
Avogadro's number A number $\left(6.022 \times 10^{23}\right.$ to four significant figures) equal to the number of atoms in exactly 12 g of carbon-12; the number of atoms, molecules, or formula units in one mole of an element or compound. (90)
axial group An atom (or group) that lies above or below the trigonal plane of a trigonal bipyramidal molecule, or a similar structural feature in a molecule. (392)

## B

background radiation Natural ionizing radiation, the most important form of which is cosmic radiation. (1084)
balancing coefficient (also stoichiometric coefficient) A numerical multiplier of all the atoms in the formula immediately following it in a chemical equation. (105)
band of stability The narrow band of stable nuclides that
Fappernonaquoticnember of neutrons versus number of protons for all nuclides. (1071)
band theory An extension of molecular orbital (MO) theory that explains many properties of metals, in particular, the differences in electrical conductivity of conductors, semiconductors, and insulators. (474)
barometer A device used to measure atmospheric pressure. Most commonly, a tube open at one end, which is filled with mercury and inverted into a dish of mercury. (189)
base In common laboratory terms, any species that produces $\mathrm{OH}^{-}$ions when dissolved in water. (150) [See also BrønstedLowry, classical (Arrhenius), and Lewis acid-base definitions.]
base-dissociation (base-ionization) constant ( $K_{\mathrm{b}}$ ) An equilibrium constant for the reaction of a base (B) with $\mathrm{H}_{2} \mathrm{O}$ to yield the conjugate acid $\left(\mathrm{BH}^{+}\right)$and $\mathrm{OH}^{-}$:

$$
\begin{equation*}
K_{\mathrm{b}}=\frac{\left[\mathrm{BH}^{+}\right]\left[\mathrm{OH}^{-}\right]}{[\mathrm{B}]} \tag{805}
\end{equation*}
$$

base pair Two complementary bases in mononucleotides that are H bonded to each other; guanine ( G ) always pairs with cytosine (C), and adenine (A) always pairs with thymine (T) (or uracil, U). (671)
base unit (also fundamental unit) A unit that defines the standard for one of the seven physical quantities in the International System of Units (SI). (18)
basic-oxygen process The method used to convert pig iron to steel, in which $\mathrm{O}_{2}$ is blown over and through molten iron to oxidize impurities and decrease the content of carbon. (1002)
battery A self-contained group of voltaic cells arranged in series. (952)
becquerel (Bq) The SI unit of radioactivity; $1 \mathrm{~Bq}=1 \mathrm{~d} / \mathrm{s}$ (disintegration per second). (1076)
bent shape (also V shape) A molecular shape that arises when a central atom is bonded to two other atoms and has one or two lone pairs; occurs as the $\mathrm{AX}_{2} \mathrm{E}$ shape class (bond angle $<120^{\circ}$ ) in the trigonal planar arrangement and as the $\mathrm{AX}_{2} \mathrm{E}_{2}$ shape class (bond angle $<109.5^{\circ}$ ) in the tetrahedral arrangement. (390)
beta ( $\boldsymbol{\beta}$ ) decay A radioactive process in which a beta particle is emitted from a nucleus. (1069)
beta particle $\left(\boldsymbol{\beta}, \boldsymbol{\beta}^{-}\right.$, or ${ }_{-1}^{0} \boldsymbol{\beta}$ ) A negatively charged particle identified as a high-speed electron that is one of the common types of radioactive emissions. (1067)
bimolecular reaction An elementary reaction involving the collision of two reactant species. (715)
binary covalent compound A compound that consists of atoms of two elements in which bonding occurs primarily through electron sharing. (70)
binary ionic compound A compound that consists of the oppositely charged ions of two elements. (60)
biomass conversion The process of applying chemical and biological methods to convert plant matter into fuels. (256)
biosphere The living systems that have inhabited Earth. (983)
blast furnace A tower-shaped furnace made of brick material in which intense heat and blasts of air are used to convert iron ore and coke to iron metal and carbon dioxide. (1000)
body-centered cubic unit cell A unit cell in which a particle lies at each corner and in the center of a cube. (464)
boiling point (bp or $T_{b}$ ) The temperature at which the vapor pressure of a gas equals the external (atmospheric) pressure. (447) boiling point elevation ( $\Delta T_{b}$ ) The increase in tho boiling Dinit of a solvent caused by the presence of dissolved solute. (529)
bond angle The angle formed by the nuclei of two surrounding atoms with the nucleus of the central atom at the vertex. (389)
bond energy (BE) (also bond enthalpy or bond strength) The enthalpy change accompanying the breakage of a given bond in a mole of gaseous molecules. $(353,557)$
bond length The distance between the nuclei of two bonded atoms. $(354,557)$
bond order The number of electron pairs shared by two bonded atoms. $(352,557)$
bonding MO A molecular orbital formed when wave functions are added to each other, which increases electron density between the nuclei. Electrons occupying such an orbital stabilize the molecule. (422)
bonding pair (also shared pair) An electron pair shared by two nuclei; the mutual attraction between the nuclei and the electron pair forms a covalent bond. (352)
Born-Haber cycle A series of hypothetical steps and their enthalpy changes needed to convert elements to an ionic compound and devised to calculate the lattice energy. (346)
Boyle's law The gas law stating that, at constant temperature and amount of gas, the volume occupied by a gas is inversely proportional to the applied (external) pressure: $V \propto 1 / P$. (194)
branch A side chain appended to a polymer backbone. (488)
bridge bond (also three-center, two-electron bond) A covalent bond in which three atoms are held together by two electrons. (583)

Brønsted-Lowry acid-base definition A model of acid-base behavior based on proton transfer, in which an acid and a base are
defined, respectively, as species that donate and accept a proton. (793)
buffer (See acid-base buffer.)
buffer capacity A measure of the ability of a buffer to resist a change in pH ; related to the total concentrations and relative proportions of buffer components. (838)
buffer range The pH range over which a buffer acts effectively. (838)

## C

calibration The process of correcting for systematic error of a measuring device by comparing it to a known standard. (32)
calorie (cal) A unit of energy defined as exactly 4.184 joules; originally defined as the heat needed to raise the temperature of 1 g of water $1^{\circ} \mathrm{C}$ (from $14.5^{\circ} \mathrm{C}$ to $15.5^{\circ} \mathrm{C}$ ). (240)
calorimeter A device used to measure the heat released or absorbed by a physical or chemical process taking place within it. (247)
capillarity (or capillary action) A property that results in a liquid rising through a narrow space against the pull of gravity. (457) carbon steel The steel that is produced by the basic-oxygen process, contains about $1 \%$ to $1.5 \% \mathrm{C}$ and other impurities, and is alloyed with metals that prevent corrosion and increase strength. (1002)
carbonyl group $\quad \mathrm{The} \mathrm{C}=\mathrm{O}$ grouping of atoms. (655)
carboxylic acid An organic compound (ending, -oic acid)
that contains the $-\stackrel{\text { O: }}{\|}-\stackrel{̣}{\mathrm{O}} \mathrm{H}$ group. (657)
catalyst A substance that increases the rate of a reaction without Ebeing aselup inthe process. (720)
cathode The electrode at which reduction occurs in an electrochemical cell. Electrons enter the cell and are acquired by the oxidizing agent at the cathode. (929)
cathode ray The ray of light emitted by the cathode (negative electrode) in a gas discharge tube; travels in straight lines, unless deflected by magnetic or electric fields. (49)
cation A positively charged ion. (60)
cell potential ( $E_{\text {cell }}$ ) (also electromotive force, or emf; cell voltage) The potential difference between the electrodes of an electrochemical cell when no current flows. (934)
Celsius scale (formerly centigrade scale) A temperature scale in which the freezing and boiling points of water are defined as $0^{\circ} \mathrm{C}$ and $100^{\circ} \mathrm{C}$, respectively. (25)
ceramic A nonmetallic, nonpolymeric solid that is hardened by heating it to high temperatures and, in most cases, consists of silicate microcrystals suspended in a glassy cementing medium. (481)
chain reaction In nuclear fission, a self-sustaining process in which neutrons released by splitting of one nucleus cause other nuclei to split, which releases more neutrons, and so on. (1094)
change in enthalpy $(\Delta H)$ The change in internal energy plus the product of the constant pressure and the change in volume: $\Delta H=\Delta E+P \Delta V$; the heat lost or gained at constant pressure: $\Delta H=q_{\mathrm{P}}$. (243)
charge density The ratio of the charge of an ion to its volume. (516) Charles's law The gas law stating that at constant pressure, the volume occupied by a fixed amount of gas is directly proportional to its absolute temperature: $V \propto T$. (195)
chelate A complex ion in which the metal ion is bonded to a bidentate or polydentate ligand. (1040)
chemical bond The force that holds two atoms together in a molecule (or formula unit). (60)
chemical change (also chemical reaction) A change in which a substance is converted into a substance with different composition and properties. (5)
chemical equation A statement that uses chemical formulas to express the identities and quantities of the substances involved in a chemical or physical change. (104)
chemical formula A notation of atomic symbols and numerical subscripts that shows the type and number of each atom in a molecule or formula unit of a substance. (64)
chemical kinetics The study of the rates and mechanisms of reactions. (685)
chemical property A characteristic of a substance that appears as it interacts with, or transforms into, other substances. (5)
chemical reaction (See chemical change.)
chemistry The scientific study of matter and its properties, the changes it undergoes, and the energy associated with those changes. (4)
chiral molecule One that is not superimposable on its mirror image; an optically active molecule. In organic compounds, a chiral molecule typically contains a C atom bonded to four different groups (asymmetric C). (639)
chlor-alkali process An industrial method that electrolyzes concentrated aqueous NaCl and produces $\mathrm{Cl}_{2}, \mathrm{H}_{2}$, and NaOH . (101)
chromatography A separation technique in which a mixture is dissolved in a fluid (gas or liquid), and the components are separated through differences in adsorption to (or solubility in) a solid surface (or viscous liquid). (77)
cis-trans isomers (See geometric isomers.)
Apago PD
classical (Arrhenius) acid-base definition A model of acidbase behavior in which an acid is a substance that has H in its formula and produces $\mathrm{H}^{+}$in water, and a base is a substance that has OH in its formula and produces $\mathrm{OH}^{-}$in water. (784)
Clausius-Clapeyron equation An equation that expresses the relationship between vapor pressure $P$ of a liquid and temperature $T$ :

$$
\begin{equation*}
\ln P=\frac{-\Delta H_{\text {vap }}}{R}\left(\frac{1}{T}\right)+C, \text { where } C \text { is a constant } \tag{446}
\end{equation*}
$$

coal gasification An industrial process for altering the large molecules in coal to sulfur-free gaseous fuels. (256)
colligative property A property of a solution that depends on the number, not the identity, of solute particles. (527) (See also boiling point elevation, freezing point depression, osmotic pressure, and vapor pressure lowering.)
collision frequency The average number of collisions per second that a particle undergoes. (217)
collision theory A model that explains reaction rate as the result of particles colliding with a certain minimum energy. (708)
colloid A suspension in which a solute-like phase is dispersed throughout a solvent-like phase. (539)
combustion The process of burning in air, often with release of heat and light. (11)
combustion analysis A method for determining the formula of a compound from the amounts of its combustion products; used commonly for organic compounds. (101)
common-ion effect The shift in the position of an ionic equilibrium away from an ion involved in the process that is caused by the addition or presence of that ion. (833)
complex (See coordination compound.)
complex ion An ion consisting of a central metal ion bonded covalently to molecules and/or anions called ligands $(862,1037)$
composition The types and amounts of simpler substances that make up a sample of matter. (4)
compound A substance composed of two or more elements that are chemically combined in fixed proportions. (42)
concentration A measure of the quantity of solute dissolved in a given quantity of solution. (121)
concentration cell A voltaic cell in which both compartments contain the same components but at different concentrations. (948)
condensation The process of a gas changing into a liquid. (438) condensation polymer A polymer formed by monomers with two functional groups that are linked together in a dehydrationcondensation reaction. (664)
conduction band In band theory, the empty, higher energy portion of the band of molecular orbitals into which electrons move when conducting heat and electricity. (474)
conductor A substance (usually a metal) that conducts an electric current well. (475)
conjugate acid-base pair Two species related to each other through the gain or loss of a proton; the acid has one more proton than its conjugate base. (795)
constitutional isomers (also structural isomers) Compounds with the same molecular formula but different arrangements of atoms. $(637,1043)$
contact process An industrial process for the manufacture of sulfuric acid based on the catalyzed oxidation of $\mathrm{SO}_{2}$. (1012)
Fontroted experimente An experiment that measures the effect of one variable at a time by keeping other variables constant. (13) conversion factor A ratio of equivalent quantities that is equal to 1 and used to convert the units of a quantity. (14)
coordinate covalent bond A covalent bond formed when one atom donates both electrons to provide the shared pair and, once formed, is identical to any covalent single bond. (1046)
coordination compound (also complex) A substance containing at least one complex ion. (1037)
coordination isomers Two or more coordination compounds with the same composition in which the complex ions have different ligand arrangements. (1043)
coordination number In a crystal, the number of nearest neighbors surrounding a particle. (464) In a complex, the number of ligand atoms bonded to the central metal ion. (1038)
copolymer A polymer that consists of two or more types of monomer. (489)
core The dense, innermost region of Earth. (981)
core electrons (See inner electrons.)
corrosion The natural redox process that results in unwanted oxidation of a metal. (956)
coulomb (C) The SI unit of electric charge. One coulomb is the charge of $6.242 \times 10^{18}$ electrons; one electron possesses a charge of $1.602 \times 10^{-19}$ C. (934)
Coulomb's law A law stating that the electrostatic force associated with two charges A and B is directly proportional to the product of their magnitudes and inversely proportional to the square of the distance between them:

$$
\begin{equation*}
\text { electrostatic force } \propto \frac{\text { charge } \mathrm{A} \times \text { charge } \mathrm{B}}{\text { distance }} \tag{348}
\end{equation*}
$$

counter ion A simple ion associated with a complex ion in a coordination compound. (1037)
coupling of reactions The pairing of reactions of which one releases enough free energy for the other to occur. (907)
covalent bond A type of bond in which atoms are bonded through the sharing of two electrons; the mutual attraction of the nuclei and an electron pair that holds atoms together in a molecule. $(62,351)$
covalent bonding The idealized bonding type that is based on localized electron-pair sharing between two atoms with little difference in their tendencies to lose or gain electrons (most commonly nonmetals). ( 342,556 )
covalent compound A compound that consists of atoms bonded together by shared electron pairs. (60)
covalent radius One-half the distance between nuclei of identical covalently bonded atoms. (318)
critical mass The minimum mass needed to achieve a chain reaction. (1095)
critical point The point on a phase diagram above which the vapor cannot be condensed to a liquid; the end of the liquid-gas curve. (448)
crosslink A branch that covalently joins one polymer chain to another. (488)
crust The thin, light, heterogeneous outer layer of Earth. (981)
crystal defect Any of a variety of disruptions in the regularity of a crystal structure. (477)
crystal field splitting energy ( $\Delta$ ) The difference in energy between two sets of metal-ion $d$ orbitals that results from electrostatic interactions with the surrounding ligands. (1050)
crystal field theory A model that explainsthe coloD ${ }^{[n+1}$ magnetism of coordination compounds based on the effects of ligands on metal-ion $d$-orbital energies. (1048)
crystalline solid Solid with a well-defined shape because of the orderly arrangement of the atoms, molecules, or ions. (463)
crystallization A technique used to separate and purify the components of a mixture through differences in solubility in which a component comes out of solution as crystals. (76)
cubic closest packing A crystal structure based on the facecentered cubic unit cell in which the layers have an $a b c a b c \ldots$ pattern. (466)
cubic meter $\left(\mathrm{m}^{3}\right) \quad$ The SI-derived unit of volume. (19)
curie (Ci) The most common unit of radioactivity, defined as the number of nuclei disintegrating each second in 1 g of radium-226; $1 \mathrm{Ci}=3.70 \times 10^{10} \mathrm{~d} / \mathrm{s}$ (disintegrations per second). (1076)
cyclic hydrocarbon A hydrocarbon with one or more rings in its structure. (637)

## D

d orbital An atomic orbital with $l=2$. (294)
dalton (Da) A unit of mass identical to atomic mass unit. (54)
Dalton's law of partial pressures A gas law stating that, in a mixture of unreacting gases, the total pressure is the sum of the partial pressures of the individual gases: $P_{\text {total }}=P_{1}+P_{2}+\cdots$. (206)
data Pieces of quantitative information obtained by observation. (13)
de Broglie wavelength The wavelength of a moving particle obtained from the de Broglie equation: $\lambda=h / m u$. (284)
decay constant The rate constant $k$ for radioactive decay. (1076)
decay series (also disintegration series) The succession of steps a parent nucleus undergoes as it decays into a stable daughter nucleus. (1074)
degree of polymerization ( $n$ ) The number of monomer repeat units in a polymer chain. (484)
dehydration-condensation reaction A reaction in which H and OH groups on two molecules react to form water as one of the products. (602)
delocalization (See electron-pair delocalization.)
density (d) An intensive physical property of a substance at a given temperature and pressure, defined as the ratio of the mass to the volume: $d=m / V$. (22)
deposition The process of changing directly from gas to solid. (439)
derived unit Any of various combinations of the seven SI base units. (18)
desalination A process used to remove large amounts of ions from seawater, usually by reverse osmosis. (542)
deuterons Nuclei of the stable hydrogen isotope deuterium, ${ }^{2} \mathrm{H}$. (1081)
diagonal relationship Physical and chemical similarities between a Period 2 element and one located diagonally down and to the right in Period 3. (575)
diamagnetism The tendency of a species not to be attracted (or to be slightly repelled) by a magnetic field as a result of its electrons being paired. $(330,1029)$
differentiation The geochemical process of forming regions in Earth based on differences in composition and density. (981)
diffraction The phenomenon in which a wave striking the edge
Fgfangaject bendsaround it. A wave passing through a slit as wide as its wavelength forms a circular wave. (273)
diffusion The movement of one fluid through another. (216)
dimensional analysis (also factor-label method) A calculation method in which arithmetic steps are accompanied by the appropriate canceling of units. (16)
dipole-dipole force The intermolecular attraction between oppositely charged poles of nearby polar molecules. (451)
dipole-induced dipole force The intermolecular attraction between a polar molecule and the oppositely charged pole it induces in a nearby molecule. (503)
dipole moment ( $\mu$ ) A measure of molecular polarity; the magnitude of the partial charges on the ends of a molecule (in coulombs) times the distance between them (in meters). (399)
disaccharide An organic compound formed by a dehydrationcondensation reaction between two simple sugars (monosaccharides). (666)
disintegration series (See decay series.)
dispersion force (also London force) The intermolecular attraction between all particles as a result of instantaneous polarizations of their electron clouds; the intermolecular force primarily responsible for the condensed states of nonpolar substances. (454)
disproportionation A reaction in which a given substance is both oxidized and reduced. (600)
distillation A separation technique in which a more volatile component of a mixture vaporizes and condenses separately from the less volatile components. (76)
donor atom An atom that donates a lone pair of electrons to form a covalent bond, usually from ligand to metal ion in a complex. (1039)
doping Adding small amounts of other elements into the crystal structure of a semiconductor to enhance a specific property, usually conductivity. (477)
double bond A covalent bond that consists of two bonding pairs; two atoms sharing four electrons in the form of one $\sigma$ and one $\pi$ bond. $(352,419)$
double helix The two intertwined polynucleotide strands held together by H bonds that form the structure of DNA (deoxyribonucleic acid). $(513,671)$
Downs cell An industrial apparatus that electrolyzes molten NaCl to produce sodium and chlorine. (999)
dynamic equilibrium The condition at which the forward and reverse reactions are taking place at the same rate, so there is no net change in the amounts of reactants or products. (173)

## E

$\boldsymbol{e}_{\boldsymbol{g}}$ orbitals The set of orbitals (composed of $d_{x^{2}-y^{2}}$ and $d_{z^{2}}$ ) that results when the energies of the metal-ion $d$ orbitals are split by a ligand field. This set is higher in energy than the other $\left(t_{2 g}\right)$ set in an octahedral field of ligands and lower in energy in a tetrahedral field. (1050)
effective collision A collision in which the particles meet with sufficient energy and an orientation that allows them to react. (710)
effective nuclear charge $\left(Z_{\text {eff }}\right)$ The nuclear charge an electron actually experiences as a result of shielding effects due to the presence of other electrons. (306)
effusion The process by which a gas escapes from its container through a tiny hole into an evacuated space. (215)
elastomer A polymeric material that can be stretched and springs back to its original shape when released.. 488 )
electrochemical cell A system that incorporates a redox reaction to produce or use electrical energy. (923)
electrochemistry The study of the relationship between chemical change and electrical work. (923)
electrode The part of an electrochemical cell that conducts the electricity between the cell and the surroundings. (928)
electrolysis The nonspontaneous lysing (splitting) of a substance, often to its component elements, by supplying electrical energy. (961)
electrolyte A substance that conducts a current when it dissolves in water. $(142,527)$ A mixture of ions, in which the electrodes of an electrochemical cell are immersed, that conducts a current. (928)
electrolytic cell An electrochemical system that uses electrical energy to drive a nonspontaneous chemical reaction ( $\Delta G>0$ ). (928)
electromagnetic radiation (also electromagnetic energy or radiant energy) Oscillating, perpendicular electric and magnetic fields moving simultaneously through space as waves and manifested as visible light, x-rays, microwaves, radio waves, and so on. (269)
electromagnetic spectrum The continuum of wavelengths of radiant energy. (271)
electromotive force (emf) (See cell potential.)
electron ( ${ }^{-}$) A subatomic particle that possesses a unit negative charge $\left(-1.60218 \times 10^{-19} \mathrm{C}\right)$ and occupies the space around the atomic nucleus. (52)
electron affinity (EA) The energy change (in kJ ) accompanying the addition of one mole of electrons to one mole of gaseous atoms or ions. (324)
electron capture A type of radioactive decay in which a nucleus draws in an orbital electron, usually one from the lowest energy level, and releases energy. (1069)
electron cloud An imaginary representation of an electron's rapidly changing position around the nucleus over time. (289)
electron configuration The distribution of electrons within the orbitals of the atoms of an element; also the notation for such a distribution. $(303,554)$
electron deficient Referring to a bonded atom, such as Be or B, that has fewer than eight valence electrons. (384)
electron density diagram (also electron probability density diagram) The pictorial representation for a given energy sublevel of the quantity $\psi^{2}$ (the probability density of the electron lying within a particular tiny volume) as a function of $r$ (distance from the nucleus). (288)
electron-pair delocalization (also delocalization) The process by which electron density is spread over several atoms rather than remaining between two. (382)
electron-sea model A qualitative description of metallic bonding proposing that metal atoms pool their valence electrons into a delocalized "sea" of electrons in which the metal cores (metal ions) are submerged in an orderly array. (369)
electron volt (eV) The energy (in joules, J) that an electron acquires when it moves through a potential difference of 1 volt; $1 \mathrm{eV}=1.602 \times 10^{-19} \mathrm{~J}$. (1092)
electronegativity (EN) The relative ability of a bonded atom to attract shared electrons. $(363,555)$
electronegativity difference ( $\triangle \mathrm{EN}$ ) The difference in electronegativities between the atoms in a bond. (366)
electrorefining natindustrial electrolytic process in which a sample of impure metal acts as the anode and a sample of the pure metal acts as the cathode. (997)
element The simplest type of substance with unique physical and chemical properties. An element consists of only one kind of atom, so it cannot be broken down into simpler substances. (41)
elementary reaction (also elementary step) A simple reaction that describes a single molecular event in a proposed reaction mechanism. (715)
elimination reaction A type of organic reaction in which C atoms are bonded to fewer atoms in the product than in the reactant, which leads to multiple bonding. (648)
emission spectrum The line spectrum produced when excited atoms return to lower energy levels and emit photons characteristic of the element. (281)
empirical formula A chemical formula that shows the lowest relative number of atoms of each element in a compound. (64)
enantiomers (See optical isomers.)
end point The point in a titration at which the indicator changes color. $(154,844)$
end-to-end overlap Overlap of $s, p$, or hybrid atomic orbitals that yields a sigma ( $\sigma$ ) bond. (557)
endothermic process A process that occurs with an absorption of heat from the surroundings and therefore an increase in the enthalpy of the system $(\Delta H>0)$. (244)
energy The capacity to do work, that is, to move matter. (8) [See also kinetic energy $\left(E_{\mathrm{k}}\right)$ and potential energy $\left(E_{\mathrm{p}}\right)$.]
enthalpy $(H) \quad$ A thermodynamic quantity that is the sum of the internal energy plus the product of the pressure and volume. (243) enthalpy diagram A graphic depiction of the enthalpy change of a system. (244)
enthalpy of hydration ( $\Delta H_{\text {hydr }}$ ) (See heat of hydration.) enthalpy of solution $\left(\Delta H_{\text {soln }}\right)$ (See heat of solution.)
entropy ( $S$ ) A thermodynamic quantity related to the number of ways the energy of a system can be dispersed through the motions of its particles. $(517,884)$
environmental cycle The physical, chemical, and biological paths through which the atoms of an element move within Earth's crust. (986)
enzyme A biological macromolecule (usually a protein) that acts as a catalyst. (723)
enzyme-substrate complex (ES) The intermediate in an enzyme-catalyzed reaction, which consists of enzyme and substrate(s) and whose concentration determines the rate of product formation. (724)
equatorial group An atom (or group) that lies in the trigonal plane of a trigonal bipyramidal molecule, or a similar structural feature in a molecule. (392)
equilibrium constant ( $\boldsymbol{K}$ ) The value obtained when equilibrium concentrations are substituted into the reaction quotient. (740)
equivalence point The point in a titration when the number of moles of the added species is stoichiometrically equivalent to the original number of moles of the other species. $(154,843)$
ester An organic compound that contains the group. (657)

exact number A quantity, usually obtained by counting or based on a unit definition, that has no uncertainty associated with it and, therefore, contains as many significant figures as a calculation requires. (30)
quires. (30
exchange reaction (See metathesis reattion.)
ODF
excited state Any electron configuration of an atom or molecule other than the lowest energy (ground) state. (278)
exclusion principle A principle developed by Wolfgang Pauli stating that no two electrons in an atom can have the same set of four quantum numbers. The principle arises from the fact that an orbital has a maximum occupancy of two electrons and their spins are paired. (305)
exothermic process A process that occurs with a release of heat to the surroundings and therefore a decrease in the enthalpy of the system $(\Delta H<0)$. (233)
expanded valence shell A valence level that can accommodate more than eight electrons by using available $d$ orbitals; occurs only with large central nonmetal atoms from Period 3 or higher. (385)
experiment A clear set of procedural steps that tests a hypothesis. (13)
extensive property A property, such as mass, that depends on the quantity of substance present. (22)
extraction A method of separating the components of a mixture based on differences in their solubility in a nonmiscible solvent. (76)

## F

face-centered cubic unit cell A unit cell in which a particle occurs at each corner and in the center of each face of a cube. (464) Faraday constant (F) The physical constant representing the charge of 1 mol of electrons: $F=96,485 \mathrm{C} / \mathrm{mol} \mathrm{e}^{-}$. (943)
fatty acid A carboxylic acid that has a long hydrocarbon chain and is derived from a natural source. (658)
filtration A method of separating the components of a mixture on the basis of differences in particle size. (76)
first law of thermodynamics (See law of conservation of energy.)
fission The process by which a heavier nucleus splits into lighter nuclei with the release of energy. (1090)
fixation A chemical/biochemical process that converts a gaseous substance in the environment into a condensed form that can be used by organisms. (987)
flame test A procedure for identifying the presence of metal ions in which a granule of a compound or a drop of its solution is placed in a flame to observe a characteristic color. (281)
flotation A metallurgical process in which oil and detergent are mixed with pulverized ore in water to create a slurry that separates the mineral from the gangue. (994)
formal charge The hypothetical charge on an atom in a molecule or ion, equal to the number of valence electrons minus the sum of all the unshared and half the shared valence electrons. (383) formation constant $\left(K_{\mathrm{f}}\right)$ An equilibrium constant for the formation of a complex ion from the hydrated metal ion and ligands. (865)
formation equation An equation in which 1 mole of a compound forms from its elements. (253)
formula mass The sum (in amu) of the atomic masses of a formula unit of an ionic compound. (72)
formula unit The chemical unit of a compound that contains the relative numbers of the types of atoms or ions expressed in the chemical formula. (66)
fossil fuel Any fuel, including coal, petroleum, and natural gas, derived from the products of the decay of dead organisms. (256)
Efractiom by mass $\subseteq$ (also mass fraction) The portion of a compound's mass contributed by an element; the mass of an element in a compound divided by the mass of the compound. (44)
fractional distillation A process involving numerous vaporization-condensation steps used to separate two or more volatile components. (536)
free energy ( $G$ ) A thermodynamic quantity that is the difference between the enthalpy and the product of the absolute temperature and the entropy: $G=H-T S$. (899)
free radical A molecular or atomic species with one or more unpaired electrons, which typically make it very reactive. (385, 1084)
freezing The process of cooling a liquid until it solidifies. (438)
freezing point depression $\left(\Delta T_{f}\right)$ A lowering of the freezing point of a solvent caused by the presence of dissolved solute particles. (531)
frequency ( $\boldsymbol{v}$ ) The number of cycles a wave undergoes per second, expressed in units of $1 /$ second, or $\mathrm{s}^{-1}$ [also called hertz (Hz)]. (270)
frequency factor ( $A$ ) The product of the collision frequency $Z$ and an orientation probability factor $p$ that is specific for a reaction. (710)
fuel cell (also flow battery) A battery that is not self-contained and in which electricity is generated by the controlled oxidation of a fuel. (955)
functional group A specific combination of atoms, typically containing a carbon-carbon multiple bond and/or carbonheteroatom bond, that reacts in a characteristic way no matter what molecule it occurs in. (631)
fundamental unit (See base unit.)
fusion (See melting.)
fusion (nuclear) The process by which light nuclei combine to form a heavier nucleus with the release of energy. (1090)
G
galvanic cell (See voltaic cell.)
gamma emission The type of radioactive decay in which gamma rays are emitted from an excited nucleus. (1070)
gamma ( $\gamma$ ) ray A very high-energy photon. (1067)
gangue In an ore, the debris, such as sand, rock, and clay, attached to the mineral. (993)
gas One of the three states of matter. A gas fills its container regardless of the shape. (6)
Geiger-Müller counter An ionization counter that detects radioactive emissions through their ionization of gas atoms within the instrument. (1075)
genetic code The set of three-base sequences that is translated into specific amino acids during the process of protein synthesis. (671)
geometric isomers (also cis-trans isomers or diastereomers) Stereoisomers in which the molecules have the same connections between atoms but differ in the spatial arrangements of the atoms. The cis isomer has similar groups on the same side of a structural feature; the trans isomer has them on opposite sides. $(641,1044)$ Graham's law of effusion A gas law stating that the rate of effusion of a gas is inversely proportional to the square root of its density (or molar mass):

$$
\begin{equation*}
\text { rate } \propto \frac{1}{\sqrt{M}} \tag{215}
\end{equation*}
$$

gray (Gy) The SI unit of absorbed radiation dose; $1 \mathrm{~Gy}=$ $1 \mathrm{~J} / \mathrm{kg}$ tissue. (1083)

Apago P. green chemistry Field that is focused on developing methods to
synthesize compounds efficiently and reduce or prevent the release of harmful products into the environment. (120)
ground state The electron configuration of an atom or ion that is lowest in energy. (278)
group A vertical column in the periodic table. (57)

## H

Haber process An industrial process used to form ammonia from its elements. (771)
half-cell A portion of an electrochemical cell in which a halfreaction takes place. (930)
half-life $\left(t_{1 / 2}\right)$ In chemical processes, the time required for half the initial reactant concentration to be consumed. (702) In nuclear processes, the time required for half the initial number of nuclei in a sample to decay. (1076)
half-reaction method A method of balancing redox reactions by treating the oxidation and reduction half-reactions separately. (924)
haloalkane (also alkyl halide) A hydrocarbon with one or more halogen atoms $(\mathrm{X})$ in place of H ; contains a $-\underset{\mid}{\mathrm{C}}-\ddot{\mathrm{X}}$ : group. (652)
hard water Water that contains large amounts of divalent cations, especially $\mathrm{Ca}^{2+}$ and $\mathrm{Mg}^{2+}$. (542)
heat $(q)$ (also thermal energy) The energy transferred between objects because of differences in their temperatures only. $(24,238)$
heat capacity The quantity of heat required to change the temperature of an object by 1 K . (246)
heat of formation $\left(\Delta H_{f}\right)$ The enthalpy change occurring when 1 mol of a compound is produced from its elements; designated $\Delta H_{\mathrm{f}}^{\circ}$ at the standard state. (245)
heat of fusion ( $\Delta H_{\text {fus }}$ ) The enthalpy change occurring when 1 mol of a solid substance melts; designated $\Delta H_{\text {fus }}^{\circ}$ at the standard state. (245) heat of hydration ( $\Delta H_{\text {hydr }}$ ) The enthalpy change occurring when 1 mol of a gaseous species is hydrated. The sum of the enthalpies from separating water molecules and mixing the gaseous species with them; designated $\Delta H_{\text {hydr }}^{\circ}$ at the standard state. (516)
heat of reaction $\left(\Delta H_{\mathrm{rxn}}\right) \quad$ The enthalpy change of a reaction; designated $\Delta H_{\mathrm{rxn}}^{\circ}$ at the standard state. (244)
heat of solution ( $\Delta H_{\text {soln }}$ ) The enthalpy change occurring when a solution forms from solute and solvent. The sum of the enthalpies from separating solute and solvent molecules and mixing them; designated $\Delta H_{\text {soln }}^{\circ}$ at the standard state. (515)
heat of sublimation $\left(\Delta H_{\text {subl }}\right)$ The enthalpy change occurring when 1 mol of a solid substance changes directly to a gas. The sum of the heats of fusion and vaporization; designated $\Delta H_{\text {subl }}^{\circ}$ at the standard state. (439)
heat of vaporization ( $\Delta H_{\text {vap }}$ ) The enthalpy change occurring when 1 mol of a liquid substance vaporizes; designated $\Delta H_{\text {vap }}^{\circ}$ at the standard state. (245)
heating-cooling curve A plot of temperature vs. time for a substance when heat is absorbed or released by the system at a constant rate. (440)
Henderson-Hasselbalch equation An equation for calculating the pH of a buffer system:

$$
\begin{equation*}
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \left(\frac{[\text { base }]}{[\text { acid }]}\right) \tag{837}
\end{equation*}
$$

EHenty'staw ander stating that the solubility of a gas in a liquid is directly proportional to the partial pressure of the gas above the liquid: $S_{\text {gas }}=k_{\mathrm{H}} \times P_{\text {gas. }}$. (522)
Hess's law of heat summation A law stating that the enthalpy change of an overall process is the sum of the enthalpy changes of the individual steps of the process. (251)
heteroatom Any atom in an organic compound other than C or H. (631)
heterogeneous catalyst A catalyst that occurs in a different phase from the reactants, usually a solid interacting with gaseous or liquid reactants. (722)
heterogeneous mixture A mixture that has one or more visible boundaries among its components. (75)
hexagonal closest packing A crystal structure based on the hexagonal unit cell in which the layers have an $a b a b \ldots$ pattern. (466)
high-spin complex Complex ion that has the same number of unpaired electrons as in the isolated metal ion; contains weak-field ligands. (1052)
homogeneous catalyst A catalyst (gas, liquid, or soluble solid) that exists in the same phase as the reactants. (721)
homogeneous mixture (also solution) A mixture that has no visible boundaries among its components. (75)
homologous series A series of organic compounds in which each member differs from the next by a $-\mathrm{CH}_{2}-$ (methylene) group. (635)
homonuclear diatomic molecule A molecule composed of two identical atoms. (424)
Hund's rule A principle stating that when orbitals of equal energy are available, the electron configuration of lowest energy
has the maximum number of unpaired electrons with parallel spins. (309)
hybrid orbital An atomic orbital postulated to form during bonding by the mathematical mixing of specific combinations of nonequivalent orbitals in a given atom. (412)
hybridization A postulated process of orbital mixing to form hybrid orbitals. (412)
hydrate A compound in which a specific number of water molecules are associated with each formula unit. (69)
hydration Solvation in water. (515)
hydration shell The oriented cluster of water molecules that surrounds an ion in aqueous solution. (502)
hydrocarbon An organic compound that contains only H and C atoms. (632)
hydrogen bond (H bond) A type of dipole-dipole force that arises between molecules that have an H atom bonded to a small, highly electronegative atom with lone pairs, usually $\mathrm{N}, \mathrm{O}$, or F . (452, 563)
hydrogenation The addition of hydrogen to a carbon-carbon multiple bond to form a carbon-carbon single bond. (722)
hydrolysis Cleaving a molecule by reaction with water, in which one part of the molecule bonds to the water - OH and the other to the water H . (659)
hydronium ion $\left(\mathrm{H}_{3} \mathrm{O}^{+}\right)$A proton covalently bonded to a water molecule. (784)
hydrosphere The liquid portion of Earth's crust. (983)
hypothesis A testable proposal made to explain an observation. If inconsistent with experimental results, a hypothesis is revised or discarded. (13)

## I <br> Apago PDF

ideal gas A hypothetical gas that exhibits linear relationships among volume, pressure, temperature, and amount (mol) at all conditions; approximated by simple gases at ordinary conditions. (193)
ideal gas law (also ideal gas equation) An equation that expresses the relationships among volume, pressure, temperature, and amount (mol) of an ideal gas: $P V=n R T$. (198)
ideal solution A solution whose vapor pressure equals the mole fraction of the solvent times the vapor pressure of the pure solvent; approximated only by very dilute solutions. (528) (See also Raoult's law.)
indicator (See acid-base indicator.)
induced-fit model A model of enzyme action that pictures the binding of the substrate as inducing the active site to change its shape and become catalytically active. (724)
infrared (IR) The region of the electromagnetic spectrum between the microwave and visible regions. (271)
infrared (IR) spectroscopy An instrumental technique for determining the types of bonds in a covalent molecule by measuring the absorption of IR radiation. (357)
initial rate The instantaneous rate occurring as soon as the reactants are mixed, that is, at $t=0$. (689)
inner electrons (also core electrons) Electrons that fill all the energy levels of an atom except the valence level; electrons also present in atoms of the previous noble gas and any completed transition series. (315)
inner transition elements The elements of the periodic table in which $f$ orbitals are being filled; the lanthanides and actinides. $(316,1030)$
instantaneous rate The reaction rate at a particular time, given by the slope of a tangent to a plot of reactant concentration vs. time. (689)
insulator A substance (usually a nonmetal) that does not conduct an electric current. (475)
integrated rate law A mathematical expression for reactant concentration as a function of time. (699)
intensive property A property, such as density, that does not depend on the quantity of substance present. (22)
interhalogen compound A compound consisting entirely of halogens. (614)
intermolecular forces (also interparticle forces) The attractive and repulsive forces among the particles-molecules, atoms, or ions-in a sample of matter. (437)
internal energy ( $E$ ) The sum of the kinetic and potential energies of all the particles in a system. (226)
ion A charged particle that forms from an atom (or covalently bonded group of atoms) when it gains or loses one or more electrons. (60)
ion-dipole force The intermolecular attractive force between an ion and a polar molecule (dipole). (450)
ion exchange A process of softening water by exchanging one type of ion (usually $\mathrm{Ca}^{2+}$ ) for another (usually $\mathrm{Na}^{+}$) by binding the ions on a specially designed resin. (542)
ion-induced dipole force The intermolecular attractive force between an ion and the dipole it induces in the electron cloud of a

## Enquitwartiche 5 52)

ion pair A pair of ions that form a gaseous ionic molecule; sometimes formed when a salt boils. (350)
ion-product constant for water ( $K_{\mathrm{w}}$ ) The equilibrium constant for the autoionization of water:

$$
\begin{equation*}
K_{\mathrm{w}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{OH}^{-}\right] \tag{789}
\end{equation*}
$$

ionic atmosphere A cluster of ions of net opposite charge surrounding a given ion in solution. (537)
ionic bonding The idealized type of bonding based on the attraction of oppositely charged ions that arise through electron transfer between atoms with large differences in their tendencies to lose or gain electrons (typically metals and nonmetals). (342, 556)
ionic compound A compound that consists of oppositely charged ions. (60, 563)
ionic radius The size of an ion as measured by the distance between the centers of adjacent ions in a crystalline ionic compound. (332)
ionic solid A solid whose unit cell contains cations and anions. (471)
ionization The process by which a substance absorbs energy from high-energy radioactive particles and loses an electron to become ionized. (1082)
ionization energy (IE) The energy (in kJ ) required to remove completely one mole of electrons from one mole of gaseous atoms or ions. $(321,555)$
ionizing radiation The high-energy radiation that forms ions in a substance by causing electron loss. (1082)
isoelectronic Having the same number and configuration of electrons as another species. (328)
isomer One of two or more compounds with the same molecular formula but different properties, often as a result of different arrangements of atoms. $(103,637,1043)$
isotopes Atoms of a given atomic number (that is, of a specific element) that have different numbers of neutrons and therefore different mass numbers. $(53,1066)$
isotopic mass The mass (in amu) of an isotope relative to the mass of carbon-12. (54)
J
joule (J) The SI unit of energy; $1 \mathrm{~J}=1 \mathrm{~kg} \cdot \mathrm{~m}^{2} / \mathrm{s}^{2}$. (240)
K
kelvin (K) The SI base unit of temperature. The kelvin is the same size as the Celsius degree. (25)
Kelvin scale (See absolute scale.)
ketone An organic compound (ending, -one) that contains a
carbonyl group bonded to two other C atoms, (655)

kilogram (kg) The SI base unit of mass. (21)
kinetic energy ( $E_{\mathrm{k}}$ ) The energy an object has because of its motion. (8)
kinetic-molecular theory The model that explains gas behavior in terms of particles in random motion whose volumes and interactions are negligible. (210)

## L

lanthanide contraction The additional decrease in atomic and ionic size, beyond the expected trend, caused by thepeorshiefding of the increasing nuclear charge by $f$ electrons in the elements following the lanthanides. (1026)
lanthanides (also rare earths) The Period $6(4 f)$ series of inner transition elements, which includes cerium $(\mathrm{Ce} ; Z=58)$ through lutetium ( $\mathrm{Lu} ; Z=71$ ). $(316,1030)$
lattice The three-dimensional arrangement of points created by choosing each point to be at the same location within each particle of a crystal; thus, the lattice consists of all points with identical surroundings. (464)
lattice energy ( $\Delta H_{\text {lattice }}^{\circ}$ ) The enthalpy change (always positive) that accompanies a solid ionic compound forming separate gaseous ions. (346)
law (See natural law.)
law of chemical equilibrium (also law of mass action) The law stating that when a system reaches equilibrium at a given temperature, the ratio of quantities that make up the reaction quotient has a constant numerical value. (741)
law of conservation of energy (also first law of thermodynamics) A basic observation that the total energy of the universe is constant: $\Delta E_{\text {universe }}=\Delta E_{\text {system }}+\Delta E_{\text {surroundings }}=0$. (240)
law of definite (or constant) composition A mass law stating that, no matter what its source, a particular compound is composed of the same elements in the same parts (fractions) by mass. (44)
law of mass action (See law of chemical equilibrium.)
law of mass conservation A mass law stating that the total mass of substances does not change during a chemical reaction. (44)
law of multiple proportions A mass law stating that if elements A and B react to form two compounds, the different masses of $B$ that combine with a fixed mass of $A$ can be expressed as a ratio of small whole numbers. (46)

Le Châtelier's principle A principle stating that if a system in a state of equilibrium is disturbed, it will undergo a change that shifts its equilibrium position in a direction that reduces the effect of the disturbance. (761)
leaching A hydrometallurgical process that extracts a metal selectively, usually through formation of a complex ion. (994)
level (also shell) A specific energy state of an atom given by the principal quantum number $n$. (290)
leveling effect The inability of a solvent to distinguish the strength of an acid (or base) that is stronger than the conjugate acid (or conjugate base) of the solvent. (816)
Lewis acid-base definition A model of acid-base behavior in which acids and bases are defined, respectively, as species that accept and donate an electron pair. (817)
Lewis electron-dot symbol A notation in which the element symbol represents the nucleus and inner electrons, and surrounding dots represent the valence electrons. (343)
Lewis structure (also Lewis formula) A structural formula consisting of electron-dot symbols, with lines as bonding pairs and dots as lone pairs. (378)
ligand A molecule or anion bonded to a central metal ion in a complex ion. $(862,1037)$
like-dissolves-like rule An empirical observation stating that substances having similar kinds of intermolecular forces dissolve in each other. (502)
limiting reactant (also limiting reagent) The reactant that is consumed when a reaction occurs and therefore the one that determines the maximum amount of product that can form. (114)
line spectrum A series of separated lines of different colors rep-
resentirg phetons whosewavelengths are characteristic of an element. (276) (See also emission spectrum.)
linear arrangement The geometric arrangement obtained when two electron groups maximize their separation around a central atom. (389)
linear shape A molecular shape formed by three atoms lying in a straight line, with a bond angle of $180^{\circ}$ (shape class $\mathrm{AX}_{2}$ or $\left.\mathrm{AX}_{2} \mathrm{E}_{3}\right) .(389,393)$
linkage isomers Coordination compounds with the same composition but with different ligand donor atoms linked to the central metal ion. (1044)
lipid Any of a class of biomolecules, including fats and oils, that are soluble in nonpolar solvents. (658)
lipid bilayer An extended sheetlike double layer of phospholipid molecules that forms in water and has the charged heads of the molecules on the surfaces of the bilayer and the nonpolar tails within the interior. (511)
liquid One of the three states of matter. A liquid fills a container to the extent of its own volume and thus forms a surface. (6)
liquid crystal A substance that flows like a liquid but packs like a crystalline solid at the molecular level. (478)
liter (L) A non-SI unit of volume equivalent to 1 cubic decimeter ( $0.001 \mathrm{~m}^{3}$ ). (19)
lithosphere The solid portion of Earth's crust. (983)
lock-and-key model A model of enzyme function that pictures the enzyme active site and the substrate as rigid shapes that fit together as a lock and key, respectively. (724)
lone pair (also unshared pair) An electron pair that is part of an atom's valence shell but not involved in covalent bonding. (352)
low-spin complex Complex ion that has fewer unpaired electrons than in the free metal ion because of the presence of strongfield ligands. (1052)

## M

macromolecule (See polymer.)
magnetic quantum number $\left(m_{l}\right)$ (also orbital-orientation quantum number) An integer from $-l$ through 0 to $+l$ that specifies the orientation of an atomic orbital in the three-dimensional space about the nucleus. (289)
manometer A device used to measure the pressure of a gas in a laboratory experiment. (191)
mantle A thick homogeneous layer of Earth's internal structure that lies between the core and the crust. (981)
mass The quantity of matter an object contains. Balances are designed to measure mass. (21)
mass-action expression (See reaction quotient.)
mass fraction (See fraction by mass.)
mass number ( $\boldsymbol{A}$ ) The total number of protons and neutrons in the nucleus of an atom. (53)
mass percent (also mass \% or percent by mass) The fraction by mass expressed as a percentage. (44) A concentration term $[\%(\mathrm{w} / \mathrm{w})]$ expressed as the mass in grams of solute dissolved per 100. g of solution. (524)
mass spectrometry An instrumental method for measuring the relative masses of particles in a sample by creating charged particles and separating them according to their mass-charge ratio. (54) matter Anything that possesses mass and occupies volume. (4) mean free path The average distance a molecule travels between collisions at a given temperature and pressurg (217) D
melting (also fusion) The change of a substance from a solid to a liquid. (438)
melting point (mp or $T_{f}$ ) The temperature at which the solid and liquid forms of a substance are at equilibrium. (447)
metabolic pathway A biochemical reaction sequence that flows in one direction and in which each reaction is enzyme catalyzed. (770)
metal A substance or mixture that is relatively shiny and malleable and is a good conductor of heat and electricity. In reactions, metals tend to transfer electrons to nonmetals and form ionic compounds. (58)
metallic bonding An idealized type of bonding based on the attraction between metal ions and their delocalized valence electrons. (343, 556) (See also electron-sea model.)
metallic radius One-half the distance between the nuclei of adjacent individual atoms in a crystal of an element. (317)
metallic solid A solid whose individual atoms are held together by metallic bonding. (472)
metalloid (also semimetal) An element with properties between those of metals and nonmetals. (58)
metallurgy The branch of materials science concerned with the extraction and utilization of metals. (993)
metathesis reaction (also double-displacement reaction or exchange reaction) A reaction in which atoms or ions of two compounds exchange bonding partners. (148)
meter ( m ) The SI base unit of length. The distance light travels in a vacuum in $1 / 299,792,458$ second. (18)
methanogenesis The process of producing methane by anaerobic biodegradation of plant and animal waste. (257)
milliliter (mL) A volume ( 0.001 L ) equivalent to $1 \mathrm{~cm}^{3}$. (19)
millimeter of mercury ( mmHg ) A unit of pressure based on the difference in the heights of mercury in a barometer or manometer. Renamed the torr in honor of Torricelli. (191)
mineral The portion of an ore that contains the element of interest, a mineral is a naturally occurring, homogeneous, crystalline inorganic solid, with a well-defined composition. (993)
miscible Soluble in any proportion. (502)
mixture A group of two or more elements and/or compounds that are physically intermingled. $(40,489)$
MO bond order One-half the difference between the number of electrons in bonding and antibonding MOs. (411)
model (also theory) A simplified conceptual picture based on experiment that explains how an aspect of nature occurs. (11)
molality ( $m$ ) A concentration term expressed as number of moles of solute dissolved in $1000 \mathrm{~g}(1 \mathrm{~kg})$ of solvent. (511)
molar heat capacity ( $C$ ) The quantity of heat required to change the temperature of 1 mol of a substance by 1 K . (235)
molar mass (M) (also gram-molecular weight) The mass of 1 mol of entities (atoms, molecules, or formula units) of a substance, in units of $\mathrm{g} / \mathrm{mol}$. (89)
molar solubility The solubility expressed in terms of amount (mol) of dissolved solute per liter of solution. (834)
molarity ( $\boldsymbol{M}$ ) A concentration term expressed as the moles of solute dissolved in 1 L of solution. $(121,522)$
mole (mol) The SI base unit for amount of a substance. The amount that contains a number of objects equal to the number of atoms in exactly 12 g of carbon-12. (90)
mole fraction ( $\boldsymbol{X}$ ) A concentration term expressed as the ratio of moles of one component of a mixture to the total moles present.

## F(20) 525 ceェ

molecular compounds Compounds that consist of individual molecules and whose physical state depends on intermolecular forces. (563)
molecular equation A chemical equation showing a reaction in solution in which reactants and products appear as intact, undissociated compounds. (145)
molecular formula A formula that shows the actual number of atoms of each element in a molecule. $(65,99)$
molecular mass (also molecular weight) The sum (in amu) of the atomic masses of a formula unit of a compound. (72)
molecular orbital (MO) An orbital of given energy and shape that extends over a molecule and can be occupied by no more than two electrons. (422)
molecular orbital (MO) diagram A depiction of the relative energy and number of electrons in each MO, as well as the atomic orbitals from which the MOs form. (423)
molecular orbital (MO) theory A model that describes a molecule as a collection of nuclei and electrons in which the electrons occupy orbitals that extend over the entire molecule. (422)
molecular polarity The overall distribution of electronic charge in a molecule, determined by its shape and bond polarities. (399) molecular shape The three-dimensional structure defined by the relative positions of the atomic nuclei in a molecule. (388)
molecular solid A solid held together by intermolecular forces between individual molecules. (470)
molecularity The number of reactant particles involved in an elementary step. (715)
molecule A structure consisting of two or more atoms that are chemically bound together and behave as an independent unit. (42)
monatomic ion An ion derived from a single atom. (60) monomer A small molecule, linked covalently to others of the same or similar type to form a polymer, on which the repeat unit of the polymer is based. (484)
mononucleotide A monomer unit of a nucleic acid, consisting of an N -containing base, a sugar, and a phosphate group. $(512,670)$
monosaccharide A simple sugar; a polyhydroxy ketone or aldehyde with three to nine C atoms. $(513,666)$

## N

nanotechnology The science and engineering of nanoscale ( $1-100 \mathrm{~nm}$ ) systems. (489)
natural law (also law) A summary, often in mathematical form, of a universal observation. (13)
Nernst equation An equation stating that the voltage of an electrochemical cell under any conditions depends on the standard cell voltage and the concentrations of the cell components:

$$
\begin{equation*}
E_{\text {cell }}=E_{\mathrm{cell}}^{\circ}-\frac{R T}{n F} \ln Q \tag{946}
\end{equation*}
$$

net ionic equation A chemical equation of a reaction in solution in which spectator ions have been omitted to show the actual chemical change. (146)
network covalent solid A solid in which all the atoms are bonded covalently. $(472,563)$
neutralization reaction An acid-base reaction that yields water and a solution of a salt; when a strong acid reacts with a stoichiometrically equivalent amount of a strong base, the solution is neutral. $(150,784)$
neutron ( $\mathrm{n}^{\circ}$ ) An uncharged subatomic particle found in the nucleus, with a mass slightly greater than that of pronel(52) PD
nitrile An organic compound containing the $-\mathrm{C} \equiv \mathrm{N}$ : group. (661)
node A region of an orbital where the probability of finding the electron is zero. (293)
nonbonding MO A molecular orbital that is not involved in bonding. (429)
nonelectrolyte A substance whose aqueous solution does not conduct an electric current. $(144,527)$
nonmetal An element that lacks metallic properties. In reactions, nonmetals tend to bond with each other to form covalent compounds or accept electrons from metals to form ionic compounds. (58)
nonpolar covalent bond A covalent bond between identical atoms such that the bonding pair is shared equally. (365)
nuclear binding energy The energy required to break 1 mole of nuclei of an element into individual nucleons. (1092)
nuclear magnetic resonance (NMR) spectroscopy An instrumental technique used to determine the molecular environment of a given type of nucleus, most often ${ }^{1} \mathrm{H}$, from its absorption of radio waves in a magnetic field. (646)
nuclear transmutation The induced conversion of one nucleus into another by bombardment with a particle. (1080)
nucleic acid An unbranched polymer consisting of mononucleotides that occurs as two types, DNA and RNA (deoxyribonucleic and ribonucleic acids), which differ chemically in the nature of the sugar portion of the mononucleotides. $(512,670)$
nucleon A subatomic particle that makes up a nucleus; a proton or neutron. (1066)
nucleus The tiny central region of the atom that contains all the positive charge and essentially all the mass. (51)
nuclide A nuclear species with specified numbers of protons and neutrons. (1066)

## 0

observation A fact obtained with the senses, often with the aid of instruments. Quantitative observations provide data that can be compared objectively. (13)
occurrence (also source) The form(s) in which an element exists in nature. (985)
octahedral arrangement The geometric arrangement obtained when six electron groups maximize their space around a central atom; when all six groups are bonding groups, the molecular shape is octahedral $\left(\mathrm{AX}_{6}\right.$; ideal bond angle $\left.=90^{\circ}\right)$. (393)
octet rule The observation that when atoms bond, they often lose, gain, or share electrons to attain a filled outer shell of eight electrons. (344)
optical isomers (also enantiomers) A pair of stereoisomers consisting of a molecule and its mirror image that cannot be superimposed on each other. $(639,1044)$
optically active Able to rotate the plane of polarized light. (640)
orbital diagram A depiction of electron number and spin in an atom's orbitals by means of arrows in a series of small boxes, lines, or circles. (308)
ore A naturally occurring compound or mixture of compounds from which an element can be profitably extracted. (985)
organic compound A compound in which carbon is nearly always bonded to itself and to hydrogen, and often to other ele-
ments. (629)
organometalic compound An organic compound in which carbon is bonded covalently to a metal atom. (656)
osmosis The process by which solvent flows through a semipermeable membrane from a dilute to a concentrated solution. (532) osmotic pressure (П) The pressure that results from the inability of solute particles to cross a semipermeable membrane. The pressure required to prevent the net movement of solvent across the membrane. (532)
outer electrons Electrons that occupy the highest energy level (highest $n$ value) and are, on average, farthest from the nucleus. (315)
overall (net) equation A chemical equation that is the sum of two or more balanced sequential equations in which a product of one becomes a reactant for the next. (112)
overvoltage The additional voltage, usually associated with gaseous products, that is required above the standard cell voltage to accomplish electrolysis. (963)
oxidation The loss of electrons by a species, accompanied by an increase in oxidation number. (159)
oxidation number (0.N.) (also oxidation state) A number equal to the magnitude of the charge an atom would have if its shared electrons were held completely by the atom that attracts them more strongly. (159)
oxidation number method A method for balancing redox reactions in which the change in oxidation numbers is used to determine balancing coefficients. (163)
oxidation-reduction reaction (also redox reaction) A process in which there is a net movement of electrons from one reactant (reducing agent) to another (oxidizing agent). (158)
oxidation state (See oxidation number.)
oxidizing agent The substance that accepts electrons in a reaction and undergoes a decrease in oxidation number. (159)
oxoanion An anion in which an element is bonded to one or more oxygen atoms. (68)

## P

$p$ block The main-group elements that lie to the right of the transition elements in the periodic table and whose $p$ orbitals are being filled. (554)
porbital An atomic orbital with $l=1$. (293)
packing efficiency The percentage of the available volume occupied by atoms, ions, or molecules in a unit cell. (466)
paramagnetism The tendency of a species with unpaired electrons to be attracted by an external magnetic field. $(330,1029)$
partial ionic character An estimate of the actual charge separation in a bond (caused by the electronegativity difference of the bonded atoms) relative to complete separation. (366)
partial pressure The portion of the total pressure contributed by a gas in a mixture of gases. (205)
particle accelerator A device used to impart high kinetic energies to nuclear particles. (1081)
pascal ( Pa ) The SI unit of pressure; $1 \mathrm{~Pa}=1 \mathrm{~N} / \mathrm{m}^{2}$. (191)
penetration The process by which an outer electron moves through the region occupied by the core electrons to spend part of its time closer to the nucleus; penetration increases the average effective nuclear charge for that electron. (307)
percent by mass (mass \%) (See mass percent.)
percent yield (\% yield) The actual yield of a reaction expressed as a percentage of the theoretical yield. (18) ago PDE period A horizontal row of the periodic table. (57)
periodic law A law stating that when the elements are arranged by atomic number, they exhibit a periodic recurrence of properties. (303)
periodic table of the elements A table in which the elements are arranged by atomic number into columns (groups) and rows (periods). (57)
pH The negative common logarithm of $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$. (791)
phase A physically distinct portion of a system. (437)
phase change A physical change from one phase to another, usually referring to a change in physical state. (437)
phase diagram A diagram used to describe the stable phases and phase changes of a substance as a function of temperature and pressure. (448)
phlogiston theory An incorrect theory of combustion proposing that a burning substance releases the undetectable material phlogiston. (11)
photoelectric effect The observation that when monochromatic light of sufficient frequency shines on a metal, an electric current is produced. (274)
photon A quantum of electromagnetic radiation. (275)
photovoltaic cell A device capable of converting light directly into electricity. (259)
physical change A change in which the physical form (or state) of a substance, but not its composition, is altered. (4)
physical property A characteristic shown by a substance itself, without interacting with or changing into other substances. (4)
pi $(\pi)$ bond A covalent bond formed by sideways overlap of two atomic orbitals that has two regions of electron density, one above and one below the internuclear axis. (419)
pi ( $\pi$ ) MO A molecular orbital formed by combination of two atomic (usually $p$ ) orbitals whose orientations are perpendicular to the internuclear axis. (425)
Planck's constant ( $h$ ) A proportionality constant relating the energy and the frequency of a photon, equal to $6.626 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}$. (274)
plastic A material that, when deformed, retains its new shape. (488)
polar covalent bond A covalent bond in which the electron pair is shared unequally, so the bond has partially negative and partially positive poles. (365)
polar molecule A molecule with an unequal distribution of charge as a result of its polar bonds and shape. (141)
polarimeter A device used to measure the rotation of planepolarized light by an optically active compound. (640)
polarizability The ease with which a particle's electron cloud can be distorted. (454)
polyatomic ion An ion in which two or more atoms are bonded covalently. (63)
polymer (also macromolecule) An extremely large molecule that results from the covalent linking of many simpler molecular units (monomers). (484)
polyprotic acid An acid with more than one ionizable proton. (803)
polysaccharide A macromolecule composed of many simple sugars linked covalently. $(513,666)$
positron ( $\boldsymbol{\beta}^{+}$) The antiparticle of an electron. (1069)
positron emission A type of radioactive decay in which a positron is emitted from a nucleus. (1069)
Epotential energye $E^{\boldsymbol{p}}$ ) The energy an object has as a result of its position relative to other objects or because of its composition. (8) precipitate The insoluble product of a precipitation reaction. (146)
precipitation reaction A reaction in which two soluble ionic compounds form an insoluble product, a precipitate. (146)
precision (also reproducibility) The closeness of a measurement to other measurements of the same phenomenon in a series of experiments. (31)
pressure ( $P$ ) The force exerted per unit of surface area. (189)
pressure-volume work ( $P V$ work) A type of work in which a volume change occurs against an external pressure. (239)
principal quantum number ( $n$ ) A positive integer that specifies the energy and relative size of an atomic orbital. (289)
probability contour A shape that defines the volume around an atomic nucleus within which an electron spends a given percentage of its time. (289)
product A substance formed in a chemical reaction. (105)
property A characteristic that gives a substance its unique identity. (4)
protein A natural, linear polymer composed of any of about 20 types of amino acid monomers linked together by peptide bonds. $(507,667)$
proton ( $\mathrm{p}^{+}$) A subatomic particle found in the nucleus that has a unit positive charge ( $1.60218 \times 10^{-19} \mathrm{C}$ ). (52)
proton acceptor A substance that accepts an $\mathrm{H}^{+}$ion; a Brønsted-Lowry base. (794)
proton donor A substance that donates an $\mathrm{H}^{+}$ion; a BrønstedLowry acid. (793)
pseudo-noble gas configuration The $(n-1) d^{10}$ configuration of a $p$-block metal atom that has emptied its outer energy level. (328)

Q
quantum A packet of energy equal to $h v$. The smallest quantity of energy that can be emitted or absorbed. (274)
quantum mechanics The branch of physics that examines the wave motion of objects on the atomic scale. (287)
quantum number A number that specifies a property of an orbital or an electron. (274)

## R

rad (radiation-absorbed dose) The quantity of radiation that results in 0.01 J of energy being absorbed per kilogram of tissue; $1 \mathrm{rad}=0.01 \mathrm{~J} / \mathrm{kg}$ tissue $=10^{-2} \mathrm{~Gy}$. (1083)
radial probability distribution plot The graphic depiction of the total probability distribution (sum of $\psi^{2}$ ) of an electron in the region near the nucleus. (289)
radioactivity The emissions resulting from the spontaneous disintegration of an unstable nucleus. (1066)
radioisotope An isotope with an unstable nucleus that decays through radioactive emissions. (1078)
radioisotopic dating A method for determining the age of an object based on the rate of decay of a particular radioactive nuclide. (1078)
radius of gyration $\left(\boldsymbol{R}_{\mathrm{g}}\right)$ A measure of the size of a coiled polymer chain as the average distance from the center of mass of the chain to its outside edge. (486)
random coil The shape adopted by most polymer chains and caused by random rotation about the bonds joining the repeat units. (485)
random error Error that occurs in all measurements (with its size depending on the measurer's skill and the instrument's precision) and results in values both higher and lower than the actual value. (31)

Raoult's law A law stating that the vapor pressure of a solution is directly proportional to the mole fraction of solvent: $P_{\text {solvent }}=X_{\text {solvent }} \times P_{\text {solvent. }}^{\circ}$. (528)
rare earths (See lanthanides.)
rate constant ( $k$ ) The proportionality constant that relates the reaction rate to reactant (and product) concentrations. (692)
rate-determining step (also rate-limiting step) The slowest step in a reaction mechanism and therefore the step that limits the overall rate. (716)
rate law (also rate equation) An equation that expresses the rate of a reaction as a function of reactant (and product) concentrations. (691)
reactant A starting substance in a chemical reaction. (105)
reaction energy diagram A graph that shows the potential energy of a reacting system as it progresses from reactants to products. (712)
reaction intermediate A substance that is formed and used up during the overall reaction and therefore does not appear in the overall equation. (715)
reaction mechanism A series of elementary steps that sum to the overall reaction and is consistent with the rate law. (714)
reaction order The exponent of a reactant concentration in a rate law that shows how the rate is affected by changes in that concentration. (692)
reaction quotient $(\mathbb{Q})$ (also mass-action expression) A ratio of terms for a given reaction consisting of product concentrations multiplied together and divided by reactant concentrations multiplied together, each raised to the power of their balancing coefficient. The value of $Q$ changes until the system reaches equilibrium, at which point it equals $K$. (741)
reaction rate The change in the concentrations of reactants (or products) with time. (687)
reactor core The part of a nuclear reactor that contains the fuel rods and generates heat from fission. (1096)
redox reaction (See oxidation-reduction reaction.)
reducing agent The substance that donates electrons in a redox reaction and undergoes an increase in oxidation number. (159)
reduction The gain of electrons by a species, accompanied by a decrease in oxidation number. (159)
refraction A phenomenon in which a wave changes its speed and therefore its direction as it passes through a phase boundary. (272) rem (roentgen equivalent for man) The unit of radiation dosage for a human based on the product of the number of rads and a factor related to the biological tissue; $1 \mathrm{rem}=10^{-2} \mathrm{~Sv}$. (1083)
resonance hybrid The weighted average of the resonance structures of a molecule. (382)
resonance structure (also resonance form) One of two or more Lewis structures for a molecule that cannot be adequately depicted by a single structure. Resonance structures differ only in the position of bonding and lone electron pairs. (381)
reverse osmosis A process for preparing drinkable water that uses an applied pressure greater than the osmotic pressure to remove ions from an aqueous solution, typically seawater. (542)
Frms (root-meanisquare) speed ( $u_{\text {rms }}$ ) The speed of a molecule having the average kinetic energy; very close to the most probable speed. (215)
roasting A pyrometallurgical process in which metal sulfides are converted to oxides. (994)
round off The process of removing digits based on a series of rules to obtain an answer with the proper number of significant figures (or decimal places). (29)

## S

$\boldsymbol{s}$ block The main-group elements that lie to the left of the transition elements in the periodic table and whose $s$ orbitals are being filled. (554)
$\boldsymbol{s}$ orbital An atomic orbital with $l=0$. (292)
salt An ionic compound that results from a classical acid-base reaction. (153)
salt bridge An inverted $U$ tube containing a solution of a nonreacting electrolyte that connects the compartments of a voltaic cell and maintains neutrality by allowing ions to flow between compartments. (930)
saturated hydrocarbon A hydrocarbon in which each C is bonded to four other atoms. (635)
saturated solution A solution that contains the maximum amount of dissolved solute at a given temperature in the presence of undissolved solute. (519)
scanning tunneling microscopy An instrumental technique that uses electrons moving across a minute gap to observe the topography of a surface on the atomic scale. (468)
Schrödinger equation An equation that describes how the electron matter-wave changes in space around the nucleus. Solutions
of the equation provide allowable energy levels of the H atom. (287)
scientific method A process of creative thinking and testing aimed at objective, verifiable discoveries of the causes of natural events. (13)
scintillation counter A device used to measure radioactivity through its excitation of atoms and their subsequent emission of light. (1075)
screening (See shielding.)
second (s) The SI base unit of time. (26)
second law of thermodynamics A law stating that a process occurs spontaneously in the direction that increases the entropy of the universe. (887)
seesaw shape A molecular shape caused by the presence of one equatorial lone pair in a trigonal bipyramidal arrangement ( $\mathrm{AX}_{4} \mathrm{E}$ ). (392)
selective precipitation The process of separating ions through differences in the solubility of their compounds with a given precipitating ion. (861)
self-ionization (See autoionization.)
semiconductor A substance whose electrical conductivity is poor at room temperature but increases significantly with rising temperature. (475)
semimetal (See metalloid.)
semipermeable membrane A membrane that allows solvent, but not solute, to pass through. (532)
shared pair (See bonding pair.)
shell (See level.)
shielding (also screening) The ability of other electrons, especially those occupying inner orbitals, todessem the nucleap atretion for an outer electron. (306)
SI unit A unit composed of one or more of the base units of the Système International d'Unités, a revised metric system. (18)
side reaction An undesired chemical reaction that consumes some of the reactant and reduces the overall yield of the desired product. (118)
side-to-side overlap Overlap of $p$ with $p$ (or sometimes with $d$ ) atomic orbitals that leads to a pi $(\pi)$ bond. (557)
sievert (Sv) The SI unit of human radiation dosage; $1 \mathrm{~Sv}=$ 100 rem. (1083)
sigma ( $\sigma$ ) bond A type of covalent bond that arises through end-to-end orbital overlap and has most of its electron density along the bond axis. (419)
sigma ( $\sigma$ ) MO A molecular orbital that is cylindrically symmetrical about an imaginary line that runs through the nuclei of the component atoms. (423)
significant figures The digits obtained in a measurement. The greater the number of significant figures, the greater the certainty of the measurement. (28)
silicate A type of compound found throughout rocks and soil and consisting of repeating $-\mathrm{Si}-\mathrm{O}$ groupings and, in most cases, metal cations. (590)
silicone A type of synthetic polymer containing - $\mathrm{Si}-\mathrm{O}$ repeat units, with organic groups and crosslinks. (590)
simple cubic unit cell A unit cell in which a particle occurs at each corner of a cube. (464)
single bond A bond that consists of one electron pair. (352)
slag A molten waste product formed in a blast furnace by the reaction of acidic silica with a basic metal oxide. (1001)
smelting Heating a mineral with a reducing agent, such as coke, to obtain a metal. (995)
soap The salt of a fatty acid and a strong base, usually a Group $1 \mathrm{~A}(1)$ or $2 \mathrm{~A}(2)$ hydroxide. (510)
solid One of the three states of matter. A solid has a fixed shape that does not conform to the container shape. (6)
solubility (S) The maximum amount of solute that dissolves in a fixed quantity of a particular solvent at a specified temperature when excess solute is present. (502)
solubility-product constant ( $\boldsymbol{K}_{\mathrm{sp}}$ ) An equilibrium constant for the dissolving of a slightly soluble ionic compound in water. (852)
solute The substance that dissolves in the solvent. $(121,502)$
solution (See homogeneous mixture.)
solvated Surrounded closely by solvent molecules. (142)
solvation The process of surrounding a solute particle with solvent particles. (515)
solvent The substance in which the solute(s) dissolve. (121, 502)
source (See occurrence.)
$s p$ hybrid orbital An orbital formed by the mixing of one $s$ and one $p$ orbital of a central atom. (412)
$\boldsymbol{s p ^ { 2 }}$ hybrid orbital An orbital formed by the mixing of one $s$ and two $p$ orbitals of a central atom. (414)
$s p^{3}$ hybrid orbital An orbital formed by the mixing of one $s$ and three $p$ orbitals of a central atom. (414)
$s p^{3} d$ hybrid orbital An orbital formed by the mixing of one $s$, three $p$, and one $d$ orbital of a central atom. (415)
$s p^{3} d^{2}$ hybrid orbital An orbital formed by the mixing of one $s$, three $p$, and two $d$ orbitals of a central atom. (416)
${ }^{0}$ spekifieheateapacity (c) The quantity of heat required to change the temperature of 1 gram of a substance by 1 K . (246)
spectator ion An ion that is present as part of a reactant but is not involved in the chemical change. (146)
spectrochemical series A ranking of ligands in terms of their ability to split $d$-orbital energies. (1051)
spectrophotometry A group of instrumental techniques that create an electromagnetic spectrum to measure the atomic and molecular energy levels of a substance. (281)
speed of light (c) A fundamental constant giving the speed at which electromagnetic radiation travels in a vacuum: $c=2.99792458 \times 10^{8} \mathrm{~m} / \mathrm{s}$. (270)
spin quantum number $\left(m_{s}\right) \quad$ A number, either $+\frac{1}{2}$ or $-\frac{1}{2}$, that indicates the direction of electron spin. (305)
spontaneous change A change that occurs by itself, that is, without an ongoing input of energy. (881)
square planar shape A molecular shape $\left(\mathrm{AX}_{4} \mathrm{E}_{2}\right)$ caused by the presence of two lone pairs at opposite vertices in an octahedral arrangement. (394)
square pyramidal shape A molecular shape $\left(\mathrm{AX}_{5} \mathrm{E}\right)$ caused by the presence of one lone pair in an octahedral arrangement. (393) standard atmosphere (atm) The average atmospheric pressure measured at sea level and $0^{\circ} \mathrm{C}$, defined as $1.01325 \times 10^{5} \mathrm{~Pa}$. (191) standard cell potential ( $E_{\text {cell }}^{\circ}$ ) The potential of a cell measured with all components in their standard states and no current flowing. (935)
standard electrode potential ( $E_{\text {half-cell }}^{\circ}$ ) (also standard half-cell potential) The standard potential of a half-cell, with the halfreaction written as a reduction. (935)
standard entropy of reaction ( $\Delta \boldsymbol{S}_{\mathrm{rxn}}^{\circ}$ ) The entropy change that occurs when all components are in their standard states. (893)
standard free energy change $\left(\boldsymbol{\Delta} \mathbf{G}^{\circ}\right)$ The free energy change that occurs when all components are in their standard states. (900)
standard free energy of formation $\left(\boldsymbol{\Delta} \boldsymbol{G}_{\mathfrak{f}}^{\circ}\right)$ The standard free energy change that occurs when 1 mol of a compound is made from its elements. (901)
standard half-cell potential (See standard electrode potential.)
standard heat of formation $\left(\Delta \boldsymbol{H}_{\mathrm{f}}^{\circ}\right)$ The enthalpy change that occurs when 1 mol of a compound forms from its elements, with all substances in their standard states. (253)
standard heat of reaction $\left(\Delta \boldsymbol{H}_{\mathrm{rxn}}^{\circ}\right)$ The enthalpy change that occurs during a reaction, with all substances in their standard states. (253)
standard hydrogen electrode (See standard reference half-cell.)
standard molar entropy ( $\boldsymbol{S}^{\circ}$ ) The entropy of 1 mol of a substance in its standard state. (888)
standard molar volume The volume of 1 mol of an ideal gas at standard temperature and pressure: 22.4141 L . (197)
standard reference half-cell (also standard hydrogen electrode) A specially prepared platinum electrode immersed in $1 \mathrm{M} \mathrm{H}^{+}(a q)$ through which $\mathrm{H}_{2}$ gas at 1 atm is bubbled. $E_{\text {half-cell }}^{\circ}$ is defined as 0 V. (936)
standard states A set of specifications used to compare thermodynamic data: 1 atm for gases behaving ideally, 1 M for dissolved species, or the pure substance for liquids and solids. (253)
standard temperature and pressure (STP) The reference conditions for a gas:

$$
0^{\circ} \mathrm{C}(273.15 \mathrm{~K}) \text { and } 1 \mathrm{~atm} \text { (760 torr) }
$$

state function A property of the system deterninedByitsurrent state, regardless of how it arrived at that state. (241)
state of matter One of the three physical forms of matter: solid, liquid, or gas. (6)
stationary state In the Bohr model, one of the allowable energy levels of the atom in which it does not release or absorb energy. (277)
steel An alloy of iron with small amounts of carbon and usually other metals. (1000)
stellar nucleosynthesis The process by which elements are formed in the stars through nuclear fusion. (1099)
stereoisomers Molecules with the same connections of atoms but different orientations of groups in space. $(639,1044)$ (See also geometric isomers and optical isomers.)
stoichiometric coefficient (See balancing coefficient.)
stoichiometry The study of the mass-mole-number relationships of chemical formulas and reactions. (90)
strong-field ligand A ligand that causes larger crystal field splitting energy and therefore is part of a low-spin complex. (1050)
strong force An attractive force that exists between all nucleons and is about 100 times stronger than the electrostatic repulsive force. (1072)
structural formula A formula that shows the actual number of atoms, their relative placement, and the bonds between them. (65) structural isomers (See constitutional isomers.)
sublevel (also subshell) An energy substate of an atom within a level. Given by the $n$ and $l$ values, the sublevel designates the size and shape of the atomic orbitals. (290)
sublimation The process by which a solid changes directly into a gas. (439)
substance A type of matter, either an element or a compound, that has a fixed composition. (41)
substitution reaction An organic reaction that occurs when an atom (or group) from one reactant substitutes for one in another reactant. (648)
substrate A reactant that binds to the active site in an enzymecatalyzed reaction. (723)
superconductivity The ability to conduct a current with no loss of energy to resistive heating. (475)
supersaturated solution An unstable solution in which more solute is dissolved than in a saturated solution. (519)
surface tension The energy required to increase the surface area of a liquid by a given amount. (457)
surroundings All parts of the universe other than the system being considered. (236)
suspension A heterogeneous mixture containing particles that are distinct from the surrounding medium. (539)
syngas Synthesis gas; a combustible mixture of CO and $\mathrm{H}_{2}$. (256)
synthetic natural gas (SNG) A gaseous fuel mixture, mostly methane, formed from coal. (256)
system The defined part of the universe under study. (236)
systematic error A type of error producing values that are all either higher or lower than the actual value, often caused by faulty equipment or a consistent fault in technique. (31)

## T

$t_{2 g}$ orbitals The set of orbitals (composed of $d_{x y}, d_{y z}$, and $d_{x z}$ ) that results when the energies of the metal-ion $d$ orbitals are split by a digand field This set is lower in energy than the other $\left(e_{g}\right)$ set in an octahedral field and higher in energy in a tetrahedral field. (1050)

T shape A molecular shape caused by the presence of two equatorial lone pairs in a trigonal bipyramidal arrangement $\left(\mathrm{AX}_{3} \mathrm{E}_{2}\right)$. (393)
temperature ( $T$ ) A measure of how hot or cold a substance is relative to another substance. (24)
tetrahedral arrangement The geometric arrangement formed when four electron groups maximize their separation around a central atom; when all four groups are bonding groups, the molecular shape is tetrahedral ( $\mathrm{AX}_{4}$; ideal bond angle $109.5^{\circ}$ ). (391)
theoretical yield The amount of product predicted by the stoichiometrically equivalent molar ratio in the balanced equation. (118)
theory (See model.)
thermochemical equation A chemical equation that shows the heat of reaction for the amounts of substances specified. (249)
thermochemistry The branch of thermodynamics that focuses on the heat involved in chemical and physical change. (236)
thermodynamics The study of heat (thermal energy) and its interconversions. (236)
thermometer A device for measuring temperature that contains a fluid that expands or contracts within a graduated tube. (24)
third law of thermodynamics A law stating that the entropy of a perfect crystal is zero at 0 K . (888)
titration A method of determining the concentration of a solution by monitoring its reaction with a solution of known concentration. (153)
torr A unit of pressure identical to 1 mmHg . (191)
total ionic equation A chemical equation for an aqueous reaction that shows all the soluble ionic substances dissociated into ions. (146)
tracer A radioisotope that signals the presence of the species of interest by emitting nonionizing radiation. (1087)
transition element (also transition metal) An element that occupies the $d$ block of the periodic table; one whose $d$ orbitals are being filled. $(313,1023)$
transition state (also activated complex) An unstable species formed in an effective collision of reactants that exists momentarily when the system is highest in energy and that can either form products or re-form reactants. (711)
transition state theory A model that explains how the energy of reactant collision is used to form a high-energy transitional species that can change to reactant or product. (711)
transuranium element An element with atomic number higher than that of uranium $(Z=92)$. (1082)
trigonal bipyramidal arrangement The geometric arrangement formed when five electron groups maximize their separation around a central atom. When all five groups are bonding groups, the molecular shape is trigonal bipyramidal $\left(\mathrm{AX}_{5}\right.$; ideal bond angles, axial-center-equatorial $90^{\circ}$ and equatorial-center-equatorial $120^{\circ}$ ). (392)
trigonal planar arrangement The geometric arrangement formed when three electron groups maximize their separation around a central atom. When all three groups are bonding groups, the molecular shape is trigonal planar $\left(\mathrm{AX}_{3}\right.$; ideal bond angle $120^{\circ}$ ). (390)
trigonal pyramid A molecular shape $\left(\mathrm{AX}_{3} \mathrm{E}\right)$ caused by the presence of one lone pair in a tetrahedral aryangemet (391)PDE triple bond A covalent bond that consists of three bonding pairs, two atoms sharing six electrons; one $\sigma$ and two $\pi$ bonds. (352)
triple point The pressure and temperature at which three phases of a substance are in equilibrium. In a phase diagram, the point at which three phase-transition curves meet. (449)
Tyndall effect The scattering of light by a colloidal suspension. (540)

## U

ultraviolet (UV) Radiation in the region of the electromagnetic spectrum between the visible and the x-ray regions. (271)
uncertainty A characteristic of every measurement that results from the inexactness of the measuring device and the necessity of estimating when taking a reading. (27)
uncertainty principle The principle stated by Werner Heisenberg that it is impossible to know simultaneously the exact position and velocity of a particle; the principle becomes important only for particles of very small mass. (286)
unimolecular reaction An elementary reaction that involves the decomposition or rearrangement of a single particle. (715)
unit cell The smallest portion of a crystal that, if repeated in all three directions, gives the crystal. (464)
universal gas constant ( $R$ ) A proportionality constant that relates the energy, amount of substance, and temperature of a system; $R=0.0820578 \mathrm{~atm} \cdot \mathrm{~L} / \mathrm{mol} \cdot \mathrm{K}=8.31447 \mathrm{~J} / \mathrm{mol} \cdot \mathrm{K}$. (198)
unsaturated hydrocarbon A hydrocarbon with at least one carbon-carbon multiple bond; one in which at least two C atoms are bonded to fewer than four atoms. (640)
unsaturated solution A solution in which more solute can be dissolved at a given temperature. (519)
unshared pair (See lone pair.)
V
V shape (See bent shape.)
valence band In band theory, the lower energy portion of the band of molecular orbitals, which is filled with valence electrons. (474)
valence bond (VB) theory A model that attempts to reconcile the shapes of molecules with those of atomic orbitals through the concepts of orbital overlap and hybridization. (411)
valence electrons The electrons involved in compound formation; in main-group elements, the electrons in the valence (outer) level. (315)
valence-shell electron-pair repulsion (VSEPR) theory A model explaining that the shapes of molecules and ions result from minimizing electron-pair repulsions around a central atom. (388)
van der Waals constants Experimentally determined positive numbers used in the van der Waals equation to account for the intermolecular attractions and molecular volume of real gases. (223)
van der Waals equation An equation that accounts for the behavior of real gases. (223)
van der Waals radius One-half of the closest distance between the nuclei of identical nonbonded atoms. (450)
vapor pressure (also equilibrium vapor pressure) The pressure exerted by a vapor at equilibrium with its liquid in a closed system. (445)
Fvapor pressure lowering ( $\Delta P$ ) The lowering of the vapor pressure of a solvent caused by the presence of dissolved solute particles. (528)
vaporization The process of changing from a liquid to a gas. (438)
variable A quantity that can have more than a single value. (13) (See also controlled experiment.)
viscosity A measure of the resistance of a liquid to flow. (458)
volatility The tendency of a substance to become a gas. (76)
volt (V) The SI unit of electric potential: $1 \mathrm{~V}=1 \mathrm{~J} / \mathrm{C}$. (934)
voltage (See cell potential.)
voltaic cell (also galvanic cell) An electrochemical cell that uses a spontaneous reaction to generate electric energy. (928)
volume ( $V$ ) The space occupied by a sample of matter. (19)
volume percent $[\%(\mathrm{v} / \mathrm{v})]$ A concentration term defined as the volume of solute in 100 . volumes of solution. (524)

## W

wastewater Used water, usually containing industrial and/or residential waste, that is treated before being returned to the environment. (542)
water softening The process of removing hard-water ions, such as $\mathrm{Ca}^{2+}$ and $\mathrm{Mg}^{2+}$, from water. (542)
wave function (See atomic orbital.)
wave-particle duality The principle stating that both matter and energy have wavelike and particle-like properties. (286)
wavelength ( $\lambda$ ) The distance between any point on a wave and the corresponding point on the next wave, that is, the distance a wave travels during one cycle. (270)
weak-field ligand A ligand that causes smaller crystal field splitting energy and therefore is part of a high-spin complex. (1050) weight The force exerted by a gravitational field on an object. (21)
work (w) The energy transferred when an object is moved by a force. (238)
X
x-ray diffraction analysis An instrumental technique used to determine spatial dimensions of a crystal structure by measuring
the diffraction patterns caused by x-rays impinging on the crystal. (468)
Z
zone refining A process used to purify metals and metalloids in which impurities are removed from a bar of the element by concentrating them in a thin molten zone. $(533,997)$

Page numbers followed by $f$ indicate figures; $m n$, margin notes; $n$, footnotes; and $t$, tables. Page numbers preceded by "A-" indicate pages in the Appendix. Page numbers preceded by "G-" indicate pages in the Glossary.

## A

AB block copolymer, 489
Absolute temperature scale, 195, G-1
Absolute zero, 25
Absorption spectrum, 281-282, 281f, 282f, G-1
Abundance, of elements, 981-986, 982f, 984t, G-1
Accuracy, 31-32, 32f, G-1
Acetaldehyde
boiling point, $452,452 f$
dipole moment, $452,452 f$
molecular structure, $651 t, 656 f$
Acetamide, molecular structure, $651 t$
Acetaminophen, molecular structure, $660 f$
Acetate ion, 68t, 833-837, $833 t$
Acetic acid
acid-dissociation constant $\left(K_{\mathrm{a}}\right), \mathrm{A}-8$
as a base, 817
boiling point elevation constant, $530 t$
depiction of molecule, 74
dissociation constant, $787 t$
dissociation of, 175, 833-837, $833 t$
equilibrium constant, $791 t$
formula, $103 t$
freezing point depression constant, $530 t$
molecular structure, $651 t$
uses, $103 t, 783 t$
Acetone $\quad$ bonds and orbitals, 421
bonds and orbitals, 42
molecular shape, 397
molecular structure, $651 t, 656 f$
nuclear magnetic resonance spectroscopy, 646, 647f
Acetonitrile
boiling point, $452 f$
dipole moment, $452 f$
molecular structure, $651 t$
Acetylene
molecular shape, $418,420,420 f$
molecular structure, $651 t$
production of, 207, $574 m n, 587$
Acetylsalicylic acid, acid-dissociation constant $\left(K_{\mathrm{a}}\right)$, A-8

## Acid(s)

acidic solutions, balancing redox reactions in, 925-926, $925 f$
Arrhenius acids, 784, 820
Brønsted-Lowry acids, 156, 793-798, 816-817, 820
buffers, 832-841
concentration, finding from titration, 154-155

## Apa

Coordinate covalent bond, 1046, G-4
Coordination compounds. See also Transition metal complexes (coordination compounds)
bidentate ligands, 1039-1040, $1039 t$
chelate, 1040
complex ions, 1037-1046, 1038f, 1039t
components of, 1038, $1038 f$
constitutional isomers, 1043-1044
coordination isomers, 1043
coordination numbers, 464, 465f, 1038, 1043
coordination theory, 1042-1043
counter ions, 1037
defined, 1037, G-4
donor atoms, 1039
enantiomers, 1044-1045, 1045f
formulas and names, 1040-1042, $1041 t$
geometric isomers, $1044,1044 \mathrm{mn}$, $1045 f$
history of, 1042-1043
isomerism, 1043-1046, 1043f, 1045f
ligands, 1037, 1038-1040, 1039t
linkage isomers, 1044
monodentate ligands, 1039, 1039t
optical isomers, $1044-1045,1045 f$
polydentate ligands, 1039-1040, 1039t
stereoisomers, 1044-1046
Werner, Alfred, 1042-1043
Coordination isomers, 1043, G-4
Coordination number, 464, 465f, 1038, 1043, G-4
Copolymer, 489, 664, G-4
Copper
abundance, $984 t$, 985
acid strength of hydrated ion, $812 t$
appearance, $1025 f$
boiling point, $390 t$
in coins, 111
in concentration cells, $949,949 f$
copper(I) and copper(II), $67 t$
cubic crystal structure, 469
as dietary trace element, $1056 t$
electrical conductance, 371
electron configuration, $313,313 t, 314,316,331$, 1024, 1025t
flame test, 281, $281 f$
flotation for recovery of, 994
isolation and electrorefining, 1002-1003, 1003f
melting point, $390 t$
oxidation states, $1028,1028 t$
properties of, $6 t$
roasting, 111-112, 113
specific heat capacity, $246 t$
in voltaic cells, 929-933, 929f, 931f, 935-939, 947-949, 959, $959 f$
Copper(I) oxide, 111-112, 113, 906
Copper(II) sulfate pentahydrate, $1029 f$
Copper(I) sulfide, 111-112, 113, 994, 1002-1003
Core, Earth, 981, 982f, G-4
Core electrons, 315
Corrosion, 956-958, 957f, 958f, G-4
Corundum, 1004
Cosmic radiation, 1084
Cosmology, element synthesis, 1099, $1100 f$
Cottrell precipitator, 540, $540 f$
Coulomb (C) (unit), 50, 934, G-4
Coulomb's law, 61, 306, 307, 348, 437, G-4
Counter ions, 1037, G-5
Counters, for detection of radioactive emissions, 1075, 1075f
Coupling of reactions, 907, G-5
Covalent bonds
bond energy, 557
bond length, 557
bond order, $352,354 t, 382$, 557
bonding pairs, 352
characteristics of, $342,342 f$
coordinate, 1046
defined, $342,351,556$, G-5
double, 381, 390, 640-641, 655-661, 818-819
formation, 62-63, 62f, 351-352, 351 $f$
intermolecular forces compared, $451 t$
lone pairs, 352
model of, 351-356
nonpolar, 365
polar, 365, 366-367
single, 378-380, 418-420, 635-637, 650-654, 657-661
triple, 420, 643, 661-662
valence bond theory. See Valence bond (VB) theory
Covalent compounds
defined, 60, G-5
dissociation, 144, 151
formation, 62-63, 62f, 158f, 159
ionic compounds compared, 63
ionic compounds distinguished from, 63
molar mass, 93
names and formulas, 70-71
network covalent solids, 355-356, 355f
oxidation number, 159
properties, $355-356,355 f$
redox reactions, 158f, 159, 168
in water, 144
Covalent hydrides, 566-567
Covalent radius, $318,354 f, 450,450 f$, G- 5
Critical mass, $1095,1095 f$, G-5
Critical point, 448, G-5
Critical pressure $\left(P_{\mathrm{c}}\right), 448-449$
Critical temperature ( $T_{\mathrm{c}}$ ), 448
Crosslinks, in polymers, 488, G-5
Crust, Earth, 981-984, 982f, 984t, 998, G-5
Crutzen, Paul J., 725
Cryolite, 581, 1004-1005
Crystal defect, in electronic materials, 477, G-5
Crystal field splitting energy, 1050, G-5
Crystal field theory
chlorophyll, 1048-1049
color and, 1048-1049, 1048f, 1049t, 1050-1051, 1050f, $1051 f$
complementary color, 1048
crystal field splitting in tetrahedral and square planar complexes, 1053-1054, $1053 f$
defined, 1048, G-5
$e_{g}$ orbitals, 1050
high-spin complexes, 1052-1053, $1052 f$
ligand field-molecular orbital theory, 1054
low-spin complexes, 1052-1053, 1052f
magnetic properties, 1052
octahedral complexes, 1049-1050, 1049f, 1050f, 1052
spectrochemical series and, 1051, $1051 f$
splitting of $d$ orbitals in an octahedral field of ligands, 1049-1050, 1049f, 1050f
square planar complexes, $1054,1054 f$
strong-field ligands, 1050, 1050f, 1052-1053, $1052 f$
$t_{2 g}$ orbitals, 1050
tetrahedral complexes, 1053, $1053 f$
weak-field ligands, 1050, 1050f, 1052-1053, $1052 f$

Crystal lattice, 464, 464f
Crystal structure
determination from atomic radius, 469
fluorite, 472, 472f, $854 f$
metals, $472,472 f$
silicon dioxide, 473
sodium chloride, 471, 471 $f$
zinc blende, 471, 471 $f$
Crystal violet, $842 f$
Crystalline solids
atomic radius determination, 469
beauty of, $463 f$
coordination number, 464, 465f
crystal lattice, $464,464 f$
defined, G-5
dissolution and, 890-891, 890f
entropy, 890-891, 890f
packing efficiency, 466, 467f
types
atomic, $470,470 f$
characteristics, $470 t$
ionic, 470t, 471-472, 471f, 472f, 558
metallic, 470t, 472, $472 f$
molecular, 470, 471f
network covalent, 470t, 472-473, 473t
unit cell, $464,465 f$, 466, 467f, 468
$x$-ray diffraction analysis of, $468,468 f, 469 f$
Crystallinity, polymer, 486, $486 f$
Crystallization, 76, 76f, G-5
Crystals. See Crystalline solids
Cubanes, 398, $398 f$
Cubic closest packing, 466, 467f, 470f, G-5
Cubic meter ( $\mathrm{m}^{3}$ ), 19-20, G-5
Curie, Marie Sklodowska, 1066-1067, 1067mn, 1080
Curie, Pierre, 1067, 1080
Curie (Ci) (unit), 1076, G-5
Curium, 1082 mn
Current. See also Electrical conductivity
electric, 18t, 49
photoelectric effect and, 274-275, $275 f$
strong electrolytes and, 527, 527f
Cyanate ion, resonance forms, 384
Cyanide ion, $68 t, 589,814$
Cyanides, solubility-product constant ( $K_{\text {sp }}$ ), A-13
Cyclic hydrocarbons, 637, 637f, G-5
Cyclo-S ${ }_{8}, 606,606 f$
Cycloalkanes, 637, $637 f$
Cyclobutane, 398
decomposition of, 700-701
molecular structure, $637 f$
Cyclohexane, molecular structure, $637 f$
Cyclone separator, 993-994, $994 f$
Cyclopentane, 637f, 894
Cyclopropane
half-life, decomposition of, 704
molecular structure, $637 f$
Cyclotron, 1081, $1081 f$
Cysteine, structure of, 508f, 667f
Cytochromes, 1056
Cytosine, 670

## D

$d$ block, 578, 1023, 1023f, 1024. See also Transition elements

## $d$ orbital

defined, 294, G-5
description, 294, $294 f$
orbital overlap, 411-412
splitting of $d$ orbitals in an octahedral field of ligands, 1049-1050, 1049f, $1050 f$
Dacron, 665
Dalton, John
atomic theory, 41, 47
career highlights, 47 mn
humidity studies, 205
law of multiple proportions, 46, 47

Fluorine
chemistry, 614-615
diatomic molecule, orbitals of, 411, 411f, 426-428, 426f, $427 f$
electron configuration, $310,311 f, 312 f$
electron density, $365,366 f$
ionization energy, $323 t$
orbital overlap, $411 f$
oxidation number, $160 t$
as oxidizing agent, 611
oxoacids, $616 t$
production of, 613
properties, 569t, 610-612
Fluorite
crystal structure, 472, 472f, $854 f$
uses, 613
Fluoro-oxy ions, in aluminum isolation, 1005
Fluorspar (fluorite), 613
Foam, 539, 539t
Food
bond strength, 361-363, 363t
combustion, 172
digestion and displacement reactions, 153 mn
irradiation of, 1090, $1090 f$
preservation, hypertonic, 534
Food chain, pollution in, 652 mn
Fool's gold, 609, 609 f
Formal charge, 383-384, 387, G-7
Formaldehyde
formula, $103 t$
molecular shape, 390
molecular structure, $656 f$
uses, $103 t$
Formate ion, 840
Formation constant ( $K_{\mathrm{f}}$ ), 865-866, 865t, A-12, G-7
Formation equation, 253-254, G-7

Formic acid, 658f, 787t, 840, A-9
Formula. See Chemical formulas
Formula mass, 72, 73, G-7
Formula unit, 66, G-7
Fossil fuels, 256, 257, G-7
Fraction by mass (mass fraction), 44-45, G-7
Fractional distillation, 536-537, 536f, G-7
Framework silicates, 593, 593f
Framework silicones, 594, 594f
Francium, 570, 570n, 571f, 572
Frasch process, 1012, 1013f
Free energy $(G)$
in biological systems, 908-909
defined, 899 , G-7
electrical work and, 943-951
electrochemistry, 943-951
Gibbs free energy, 899
Free energy change ( $\Delta \mathrm{G}$ )
calculating, 900-902
defined, 899
equilibrium, 909-910
extent of reaction, 913, 913f
reaction direction, 909-910, 913
reaction spontaneity and, 899-900, 904-907, 905t
standard cell potential and, 943-945, 944f
standard free energy change ( $\Delta G^{\circ}$ ), 900-902
standard free energy of formation ( $\Delta G_{\mathrm{f}}^{\mathrm{o}}$ ), 901-902
temperature and, 904-907, 904t
work and, 902-903
Free-radical polymerization, 664, 664f
Free radicals
biological systems, 385mn, 1084
defined, 385 , 1084, G-7
ionizing radiation and, 1084
Lewis structure, 385
nitrogen monoxide, 600 mn
ozone depletion and, 725
photochemical smog, 600, $600 f$
Freezing, 438, 442, G-7
Freezing point depression $\left(\Delta T_{\mathrm{f}}\right), 530 t, 531,533$, G-7
Freons (chlorofluorocarbons), 587
Frequency ( $v$ ), of wave, 270, 270f, 271-272, 275, G-7
Frequency factor $(A), 710-711$, G-7
Frisch, Otto, 1094
Fructose, structure, $666 f$
Fuel
bond strength, 361-363, $362 f$
combustion, 172 mn
nuclear, 215 mn
rocket, 117
Fuel cells, 172mn, 955-956, $955 f$
defined, 955, G-7
electric cars, 923 mn
microbial, 257
Fuel rods, 1096

alkynes, $643,651 t$
aromatic, $644-645,644 f, 645 \mathrm{mn}$
cyclic, $637,637 f$
defined, 632, G-9
double bonds, 640-642
isomers
constitutional isomers, 637-638, $638 t$
geometric isomers, 641-642, 641t
optical isomers, 639-640, 639f, 640f, 640mn, 641f
naming, 635-636, 635t, 636t, 643
saturated, 635
structure, 632-635, 633f
triple bonds, 643
unsaturated, 640
Hydrochloric acid. See Hydrogen chloride
Hydrochlorofluorocarbons (HCFCs), 725
Hydrocyanic acid, 787t, A-9
Hydrofluoric acid, 787t, A-9
Hydrofluorocarbons (HFCs), 725
Hydrogen
abundance, $984 t$
chemistry, 566-567
combustion, $172 \mathrm{mn}, 258$
covalent bonding, 62, 62f, 351-352, $351 f$
density, $23 t$
deuterium, 1008-1009, 1008t, 1011
displacement by metals, $170,170 f$
electron configuration, 308-309, 311f, 312f
electron density, $365,366 f$
electron distribution, $141 f$
formation from decomposition of water, 258-259
as fuel, 258-259, 567mn
fuel cells, 955-956, $955 f$
industrial production, 1009
isotopes, 1008-1009, 1008t, 1011
laboratory production, 1010
mole fraction of air at sea level, $219 t$
molecular orbitals, 422-423, 423f
orbital overlap, $411 f$
oxidation number, $160 t$
periodic table, position in, 565-566, 565f
polar nature of water, 141
reduction with, 995
tritium, 1008-1009, 1008t
uses, 1010-1011
Hydrogen atom
Bohr model, 277-279, $278 f$
energy levels of the, 295, $295 f$
energy states, 279-280, $279 f$
ionization energy, 321
line spectra, 276-277, 276f,277f
quantum number, 304
Hydrogen bisulfate ion, 609
Hydrogen bond ( H bond)
in biological systems, $453,509,512,671,673$
boiling point and, $453,453 \mathrm{f}$
defined, 452 , G-9
intermolecular forces, 451t, 452-454, 453f
physical properties, effect on, 563
significance of, 452-453
in solutions, $502,502 f$
surface tension and, 457, 457 $t$
water, 459,461
Hydrogen bromide, 151
Hydrogen carbonate ion, $68 t$
Hydrogen chloride, 613, 614
acid-base reactions, 151, 155-157
formation, 158f, 159
production, 614
stomach release of, 125-126
titration of, $843 f, 844$
uses, $613,783 t$
Hydrogen fluoride, 104, 105f, 352, 356, 359
bond polarity, $365,366 f$
electronegativity, 363
molecular orbitals, $429,429 f$
orbital overlap, $411 f$
structure, $614 m n$
uses, $613,614 m n$
Hydrogen halides, 614
Hydrogen ion, $65 t$
in acids, 150,151
Arrhenius acid-base definition and, 784-785
concentration measurement, 950-951, 951f
molarity determination, 152
Hydrogen peroxide
as disinfectant, 385 mn
molecular formula, 99
properties, 607 mn
uses, 605, 607 mn
Hydrogen phosphate ion, $68 t$
Hydrogen sulfate ion, $68 t, 609,791 t$
Hydrogen sulfide
bacterial use of, 859
on Io (Jupiter moon), 6 mn
mole fraction of air at sea level, $219 t$
removal from coal and natural gas, 763-764
uses, 605
VSEPR theory and, 418
Hydrogen sulfide ion, 852, 861-862
Hydrogen sulfite, 608
Hydrogenation
catalytic, 722, $722 f$
defined, $722, \mathrm{G}-9$
of liquid oils, 1010
Hydrohalic acids, 614, 788, 810
Hydrolases, 724
Hydrolysis, 659, G-9
Hydrolysis constant $\left(K_{\mathrm{h}}\right), 808 n$
Hydrometallurgy, 993
Hydronium ion $\left(\mathrm{H}_{3} \mathrm{O}^{+}\right), 68 t$
balancing redox reaction using, 926
calculating concentration in aqueous solution, 789-790, 790f
defined, 784, G-9
formation of, 151, 151 f
pH scale and, 791-793, $792 f$
water and, 784-787
Hydroquinone, 1035
Hydrosphere, 983, 984, 984t, G-9

Hydrosulfuric acid, acid-dissociation constant ( $K_{\mathrm{a}}$ ), 803t, A-9
Hydroxide ion, 68t, 650, 852
in bases, 150,152
calculating concentration in aqueous solution, 789-790, $790 f$

Hypobromous acid
acid-dissociation constant $\left(K_{\mathrm{a}}\right)$, A-9
equilibrium constant, $791 t$
Hypochlorite ion, 68t, 541
Hypochlorous acid, 787t, A-9
Hypofluorous acid, 611
Hypohalate, 613, 616
Hypohalous acids, 616t, 811, $811 f$
Hypoiodous acid, A-9
Hypothesis
defined, 13, G-9
in the scientific method, 13-14, 13f
Hypotonic solution, 534

## I

-ic (suffix), 67, 70
Ice, 461, 461 $f$,
-ide (suffix), 66, 70
Ideal gas, 887
defined, 193, G-9
standard molar volume, 197-198, 197f, 198f
Ideal gas law, 203-210, 748
defined, 198, G-9
in limiting-reactant problem, 209
reaction stoichiometry, 208-210, $208 f$
relationship to individual gas laws, 198
van der Waals equation and, 223-224, 223t
Ideal solution, 528, G-9
IGCC (integrated gasification combined cycle), 256
Ilmenite, $1000 t$
Inch, historic physical standard, 18 mn

## Indicator

acid-base, $154,154 f$
in redox titration, 164, $165 f$
Indium
bond type, $584 t$
melting point, $584 t$
properties, 578, 580
Indium oxide, 582
Induced-fit model, of enzyme action, $724,724 f$, G-9
Inert-pair effects, 579
Infrared (IR) radiation, 271, 271f, G-9
Infrared spectroscopy, 357-358, 357f, 358f, G-9
Initial reaction rate, 689, 693, G-9
Inner (core) electrons, 315, 318, G-9
Inner transition elements
actinides, 316, 1031
defined, 1030, G-9
electron configurations, 315-317
lanthanides, 1030-1031, 1031 mn
periodic table, $57,58 f, 1023,1023 f$
Inorganic chemistry, 59
Inorganic compounds, double bonds in, 657
Inorganic polymers, 665
Insects, irradiation of, 1090
Insoluble compounds, 142, $148 t$
Instantaneous reaction rate, 689 , G-9
Instrument calibration, 32, $32 f$
Insulator
band theory and, $475,475 f$
defined, 475, G-9
Integrated gasification combined cycle (IGCC), 256
Integrated rate law, 699-705
defined, 699, G-9
first-order reactions, 699-701, 701f, 705t half-life, 702-705, 703 f
reaction order, determining, 701-702, 701f, 702 f
second-order reactions, 700, 701f, 705t
zero-order reactions, 700, 701f, 705t
Intensive properties, 22, G-9
Interference, 273
Interhalogen compounds, 614-615, 615f, G-9

Leclanché cell, 952
Length
common examples, $23 f$
converting units of, 17
English equivalents, $19 t$
SI units, 18-19, 18t, $19 t$
Leucine, structure of, $508 f, 667 f$

Level, 290, G-10
Leveling effect, of solvent, 816-817, G-10
Levitating power, of a superconducting oxide, $476 f$
Levorotatory isomer, 640
Lewis, Gilbert Newton, 343, $344 m n$
Lewis acid-base definition, 817-820
adduct, 817-819
complex ions and, 862
defined, $817, \mathrm{G}-10$
Lewis acids, 817-820
complex ions, 862
with electron-deficient atoms, 818
metal cations as, $819,819 f$
molecules as, 818-819
with polar multiple bonds, 818-819
Lewis bases, 817-820, 862
Lewis electron-dot symbols, 343-344, 343f, G-10
Lewis structure (formula), 378-387
defined, $378,378 n$, G-10
electron-deficient molecules, 384-385
electron-pair delocalization, 382
expanded valence shells, 385-387
formal charge, 383-384, 387
free radicals, 385
molecules with multiple bonds, 380-381
molecules with single bonds, 378-380
octet rule, 378-381
exception to, 384-387
odd-electron molecules, 385
resonance, 381-383
valence-shell electron-pair repulsion theory, 388
Libby, Willard F., 1078
Life, elements of, 63
Ligand field-molecular orbital theory, 1054
Ligands
bidentate, 1039-1040, 1039t, 1050
common types of, 1039-1040, 1039t
coordination compounds and, 1037-1040, 1039t
defined, $862,1037, \mathrm{G}-10$
monodentate, 1039, $1039 t$
polydentate, 1039-1040, 1039t
spectrochemical series, $1051 f$
splitting $d$ orbitals in an octahedral field of ligands,
1049-1050, 1049f, $1050 f$
strong-field ligands, $1050,1050 f, 1052-1053,1052 f$
weak-field ligands, 1050, 1050f, 1052-1053, 1052f

Molecular hydrides, 566-567
Molecular (formula) mass
calculating, 72, 73
defined, $92 t$, G-11
Molecular orbital (MO)
antibonding, 422
bond order, 423
bonding, 422
defined, 422, G-11
energy and shape of, $423,423 f$
formation, 422-423
of hydrogen, 422-423, 423f
of lithium, 474, $474 f$
nonbonding, 429
Molecular orbital (MO) band theory, 474-476,
$474 f, 475 f$
Molecular orbital (MO) diagram, 423, 429f, G-11
Molecular orbital theory, 422-430
antibonding MO, 422
atomic $2 p$-orbital combinations, 425-426, 425f, $426 f$
benzene, 430
bonding MO, 422
central themes, 422-424
defined, 422, G-11
formation of molecular orbitals, 422-423
heteronuclear diatomic molecules
bonding in hydrogen fluoride, $429,429 f$
bonding in nitrogen oxide, $429,429 f$
homonuclear diatomic molecules, 424-429
atomic $p$-orbital combinations, 425-426, 425f, 426f
bonding in $p$-block, 426-428
bonding in $s$-block, $425,425 f$
ligand field-molecular orbital theory, 1054
MO bond order, 423
nonbonding, 429
ozone, 430
pi $(\pi)$ MOs, $425-426,425 f$
sigma ( $\sigma$ ) MOs, 423, 425f
Molecular polarity
amino acid side chains, 508
bond angle, 399
bond polarity, 399
defined, 399, G-11
dipole moment, 399-400
effect on behavior, 401
liquid solutions and, 503-506
molecular shape and, 399-401
pi $(\pi)$ bonds and, 421
Molecular shape, 377-403
beautiful and practical shapes, $398,398 f$
biological receptors and odor molecules, 402-403, $402 f-403 f$
cubanes, $398,398 f$
defined, 388, G-11
dendrimers, $398,398 f$
dispersion forces and, $455,455 f$
fullerenes, 398, $398 f$
Lewis structure (formula), 378-387
defined, $378,378 n$
electron-deficient molecules, 384-385
expanded valence levels (shells), 385-386

Molecular shape-Cont.
formal charge, 383-384, 387
molecules with multiple bonds, 380-381
molecules with single bonds, 378-380
odd-electron molecules, 385
resonance, 381-383
molecular polarity and, 399-401, $399 f$
nanotubes, $398,398 f$
valence-shell electron-pair repulsion (VSEPR) theory, 388-398, 557
bent shape, 390, 390f, 391f, 392, 394f, 415
defined, 388
electron-group arrangements, 388-389, 389f
linear arrangement, 389 , 389f, $394 f$
molecules with multiple central atoms, 396-397, $397 f$
octahedral arrangement, 389f, 393-394, 393f, 394f
seesaw shape, 392-393, $394 f$
square planar shape, $393 f, 394,394 f$
square pyramidal shape, 393 , 393f, $394 f$
T shape, $392 f, 393,394 f$
tetrahedral arrangement, 389f, 391-392, 391f, 394f
trigonal bipyramidal arrangement, 389f, 392-393, 392f, $394 f$
trigonal planar arrangement, 390, 390f, $394 f$
trigonal pyramidal shape, 389f, 391, 391f, 394f
using VSEPR to determine molecular shape, 395-396
V shape, 390, 390f, 391f, 392, 394f, 415
viscosity, effect on, 458
Molecular solids, 470, 470f, G-11
Molecular speeds, 211, 213, 214-215, 217
Molecular volume, gas pressure and, 222, $223 f$
Molecular weight. See Molecular mass
Molecularity, elementary reactions and, 715-716 $715 t$, G-11
Molecules
bonds. See Bonding
chemical formula and structure of, 102-104
defined, 42, G-11
depictions of, 74
elements, $42,42 f, 62,62 f, 92$
Lewis structures, 378-387
orbitals. See Molecular orbital (MO)

polarity. See Molecular polarity
reaction rates and structure, $710-711,711 f$
shape. See Molecular shape
Molina, Mario J., 725
Molybdenum, 316, 1030, 1030t
Monatomic element, molar mass of, 92
Monatomic ions
compounds formed from, 66
defined, G-12
formation, 60-62
metals, $67,67 t$
names and formulas, $65,65 f, 65 t$
properties of, 328-333
size trends, 558
Mono- (prefix), $69 t$
Monochromatic light, 271
Monodentate ligands, 1039, $1039 t$
Monomers, 484, G-12
Mononucleotides, 512, 670, G-12
Monoprotic acids, 787, 787t
Monosaccharides, 513, 513f, 666, 666f, G-12
Moon, atmosphere of, $220 t$
Moon rocks, radiodating, 1079 mn
Moseley, Henry, 304, 304mn
Moseley's law, 304mn
Motor oil, viscosity of, 459
Mulliken, Robert S., $364 n$
Multiple proportions, law of, 46, 47, G-10
Multiplication, significant figures and, 28
Muriatic acid, $783 t$
Muscovite mica, 592, $592 f$
Mylar, 665
Myosin, arrangement of filaments, $480 f$

## N

n-type semiconductor, 476, 477-478, 478f
N/Z (neutron-to-proton) ratio, 1070-1071, 1071f
NAA (neutron activation analysis), 1088
NAD (nicotinamide adenine dinucleotide), 967
Naming. See Nomenclature
Nano- (prefix), $19 t$
Nanocomposites, 490
Nanomachines, 491, 491f
Nanometer (nm) (unit), 270

Nanostructuring, 490
Nanotechnology, 489-491
defined, 489, G-12
high-surface-area materials, 490-491
nanomachines, 491
nanostructured materials, 490
optical materials, 490
quantum dots, $490,490 f$
self-assembly, 490
Nanotubes, 398, 398f, $585 f$
Nanotubes, carbon, 490-491
Naphthalene, 645mn
Naproxen, 640mn
Natta, Giulio, 664
Natural law, G-12
Nematic, liquid crystal phase, $480,480 f$
Neon
atomic size, 320 mn
boiling point, $506 t$
diatomic molecule, orbitals of, 426-428, 426f, 427f
electron configuration, $310,311 f, 312 f$
ionization energy, $323 t$
mass spectrometry of, $55,55 f$
molar mass of, 92
mole fraction of air at sea level, $219 t$
properties, 569t, 617-618
sign, 49mn
solubility in water, $506 t$
Neopentane
constitutional isomers, $638 t$
formula, $638 t$
molecular shape, $455,455 f$
properties, $638 t$
Neoprene, $489 t$
Neptune (planet), atmosphere, $220 t$
Nernst, Walther Hermann, 946, 946 mn
Nernst equation, 946-947, 950, G-12
Nerve cells, as concentration cells, 950 mn
Nerve poison, phosphorus, 992 mn
Net ionic equations
for acid-base reactions, $153,157,157 f$
for aqueous ionic reactions, 145f, 146
defined, 146, G-12
Aetwodrevalent compounds,563
Network covalent solids, $470 t, 472-473,473 t, \mathrm{G}-12$
Network covalent solids, 470t, 472-473, 473t, G-1
Neutralization, $783,784,841$. See also Acid-base (neutralization) reactions
Neutralization reaction. See also Acid-base reactions
defined, 150, G-12
salt formation, 152-153
Neutrino, 1069mn
Neutron ( $\mathrm{n}^{0}$ )
defined, 52, G-12
discovery, 51, 1080-1081
mass, $53 t$
nuclide and, 1066
number of, 53
properties, $53 t$
Neutron activation analysis (NAA), 1088
Neutron-capture processes, 1099
Neutron star, 1099, $1100 f$
Neutron-to-proton (N/Z) ratio, 1070-1073, $1071 f$
Newlands, John, 303
Nickel
abundance, $984 t$
acid strength of hydrated ion, $812 t$
appearance, $1025 f$
electron configuration, 313, 313t, 1025t
oxidation states, 1028, $1028 t$
Nickel-cadmium (nicad) battery, 954
Nickel-metal hydride (Ni-MH) battery, 954, 954f
Nickel(II) nitrate hexahydrate, 123, $1029 f$
Nile River, $543 m n$
Niobium, 567 mn , 1030
Nitrate ion, $68 t$
molecular shape, 390
resonance structure, 383
Nitric acid, 152, 600-601, 601f, 863
Nitric oxide
atmospheric concentration, $600 f$
biochemical uses, 600 mn
boiling point, $506 t$
formation, 600
molecular orbitals, 429, $429 f$
solubility in water, $506 t$
structures and properties, $599 t$
uses, 597
Nitride ion, $65 t$
-nitrile (suffix), $651 t$

Nitriles, 651t, 661, G-12
Nitrite ion, $68 t$
Nitrogen
abundance, $984,984 t$
boiling point, $506 t$
bond type, $584 t$
chemistry, 599-601
critical temperature, 449
diatomic molecule, orbitals of, 426-428, 426f, $427 f$
electron configuration, $309,311 f, 312 f$
fixation, 597, 771, 988-989, 989f
gas, the bends and, $522 f$
ionization energy, $323 t$
irradiation of, 1098
Lewis structure, 381
melting point, $584 t$
mole fraction in air at sea level, $219 t$
properties, $326,569 t, 595-596$
solubility in water, $506 t$
triple bond, 352
Nitrogen cycle, 988-989, $989 f$
Nitrogen dioxide
atmospheric concentration, $600 f$
depiction of molecule, 74
equilibrium with dinitrogen tetraoxide, 738-742, $739 f$, $742 f, 742 t$
formation, 600
Lewis structure, 385
mole fraction of air at sea level, $219 t$
structures and properties, $599 t$
Nitrogen family
chemical behavior, 598-599
important compounds, 597
important reactions, 597
oxygen family compared, 603, 606-608
physical behavior, 595-596
properties, 595-596, 598-603
Nitrogen fixation, 597, 771
Nitrogen monoxide, 219 t , 600 mm . See also Nitric oxide
Nitrogen oxides, 599-600, 599t, 863, 864, 892, $892 f$
Nitrogen trifluoride, 378-379
Nitrous acid, 600-601, 601f, 787t, 791t, A-10
NMR (nuclear magnetic resonance) spectroscopy
Nobelium, 1031, 646f, 647f, G-12
Noble gases
as atomic solids, 470
electron affinity, 325
electron configuration, $312,328,328 f$
ionization energy, $321 f, 325$
ions formed and nearest noble gas, $61,61 f$

Outgassing, 982, 984
Overall (net) equation, 112-113, G-12
Overvoltage, 963-964, G-12
Oxalates, solubility-product constant ( $K_{\text {sp }}$ ), A-13
Oxalic acid, acid-dissociation constant $\left(K_{\mathrm{a}}\right), 803 t, 805$, A-10
Oxidation, 923, $924 f$
defined, 159, G-12
in early Earth atmosphere, 983
as increase in oxidation number, 161
Oxidation number (O.N.)
defined, 159, 560, G-12
determining, 159-160
electronegativity and, 364-365
formal charge compared to, 384
of main-group elements, $160 f$
rules for assigning, 160, $160 t$
transition elements, $1028,1028 t$
Oxidation number method for balancing redox equations,
163-164, G-12
Oxidation-reduction reaction. See Redox reactions
Oxidation state. See also Oxidation number (O.N.)
alkali metals, 572
alkaline earth metals, 576
boron family elements, 579,580
carbon family elements, 586
coordination compound, 1041
defined, 560
halogens, 612, 614-615
main-group elements, 561
nitrogen family elements, 596
noble gases, 618
oxygen family elements, 604
primary valence, 1043
transition elements, 1028, 1028t
Oxide ion, $65 t$
Oxide superconductors, $456 f, 476$
Oxides, $985 f$, 986

[^0]:    *Compounds of the mercury $(1)$ ion, such as $\mathrm{Hg}_{2} \mathrm{Cl}_{2}$, and peroxides of the alkali metals, such as $\mathrm{Na}_{2} \mathrm{O}_{2}$, are the only two common exceptions. Their empirical formulas are HgCl and NaO , respectively.

[^1]:    *Listed alphabetically by metal name; those in boldface are most common.

[^2]:    $\mathrm{ClO}_{4}{ }^{-}$is perchlorate, $\mathrm{ClO}_{3}{ }^{-}$is chlorate, $\mathrm{ClO}_{2}{ }^{-}$is chlorite, $\mathrm{ClO}^{-}$is hypochlorite

[^3]:    1 molecule of $\mathrm{H}_{2} \mathrm{O} \quad$ has a mass of 18.02 amu and 1 mol of $\mathrm{H}_{2} \mathrm{O}\left(6.022 \times 10^{23}\right.$ molecules $)$ has a mass of 18.02 g 1 formula unit of NaCl has a mass of 58.44 amu and 1 mol of $\mathrm{NaCl}\left(6.022 \times 10^{23}\right.$ formula units) has a mass of 58.44 g

[^4]:    *The mass value in the periodic table has no units because it is a relative atomic mass, given by the atomic mass (in amu) divided by 1 amu ( $\frac{1}{12}$ mass of one ${ }^{12} \mathrm{C}$ atom in amu):

    $$
    \text { Relative atomic mass }=\frac{\text { atomic mass }(\mathrm{amu})}{\frac{1}{12} \text { mass of }{ }^{12} \mathrm{C}(\mathrm{amu})}
    $$

[^5]:    *The rms speed, $u_{\mathrm{rms}}$, is proportional to, but slightly higher than, the average speed; for an ideal gas, $u_{\mathrm{rms}}=1.09 \times$ average speed.

[^6]:    *Values in parentheses refer to interior pressures.
    ${ }^{\dagger}$ Values in parentheses refer to cloud-top temperatures.

[^7]:    *The definition of the standard state for gases has been changed to 1 bar, a slightly lower pressure than the 1 atm standard on which the data in this book are based ( $1 \mathrm{~atm}=101.3 \mathrm{kPa}=$ 1.013 bar). For most purposes, this makes very little difference in the standard enthalpy values. ${ }^{\dagger}$ In the case of phosphorus, the most common form, white phosphorus $\left(\mathrm{P}_{4}\right)$, is chosen as the standard state, even though red phosphorus is more stable at 1 atm and 298 K .

[^8]:    *A blackbody is an idealized object that absorbs all the radiation incident on it. A hollow cube with a small hole in one wall approximates a blackbody.

[^9]:    *The complete form of the Schrödinger equation in terms of the three linear axes is

    $$
    \left[-\frac{h^{2}}{8 \pi^{2} m_{e}}\left(\frac{d^{2}}{d x^{2}}+\frac{d^{2}}{d y^{2}}+\frac{d^{2}}{d z^{2}}\right)+V(x, y, z)\right] \psi(x, y, z)=E \psi(x, y, z)
    $$

    where $\psi$ is the wave function; $m_{\mathrm{e}}$ is the electron's mass; $E$ is the total quantized energy of the atomic system; and $V$ is the potential energy at point $(x, y, z)$.

[^10]:    *For ease in discussion, we refer to the size, shape, and orientation of an "atomic orbital," although we really mean the size, shape, and orientation of an "atomic orbital's radial probability distribution." This usage is common in both introductory and advanced texts.

[^11]:    *Colored type indicates the sublevel to which the last electron is added.

[^12]:    *Colored type indicates sublevel(s) whose occupancy changes when the last electron is added.

[^13]:    ${ }^{*} \mathrm{MJ} / \mathrm{mol}$, or megajoules per mole $=10^{3} \mathrm{~kJ} / \mathrm{mol}$.

[^14]:    *Tables of first electron affinity values often list them as positive if energy is absorbed to remove an electron from the anion. Keep this convention in mind when researching these values in reference texts. Electron affinities are difficult to measure, so values are frequently updated with more accurate data. Values for Group 2A(2) reflect recent changes.

[^15]:    *Strictly speaking, ionization energy (IE) and electron affinity (EA) are internal energy changes ( $\Delta E$ ),

[^16]:    *Electronegativity is not the same as electron affinity (EA), although many elements with a high EN also have a highly negative EA. Electronegativity refers to a bonded atom attracting the shared electron pair; electron affinity refers to a separate atom in the gas phase gaining an electron to form a gaseous anion.

[^17]:    *In 1934, the American physicist Robert S. Mulliken developed an approach to electronegativity based solely on atomic properties: $\mathrm{EN}=(\mathrm{IE}-\mathrm{EA}) / 2$. By this approach as well, fluorine, with a high ionization energy (IE) and a large negative electron affinity (EA), has a high EN; and cesium, with a low IE and a small EA, has a low EN.

[^18]:    *Even though beryllium is an alkaline earth metal [Group 2A(2)], most of its compounds have properties consistent with covalent, rather than ionic, bonding (Chapter 14). For example, molten $\mathrm{BeCl}_{2}$ does not conduct electricity, indicating the absence of ions.

[^19]:    *Reactions of the sort shown here, in which one species "donates" an electron pair to another to form a covalent bond, are examples of Lewis acid-base reactions (Chapter 18).

[^20]:    *The two electron pairs in a double bond (or the three pairs in a triple bond) occupy separate orbitals, so they remain near each other and act as one electron group (see Chapter 11).

[^21]:    *H-bond-type interactions occur with the larger atoms $\mathrm{P}, \mathrm{S}$, and Cl , but those are so much weaker than the interactions with $\mathrm{N}, \mathrm{O}$, and F that we will not consider them.

[^22]:    *The units of viscosity are newtonseconds per square meter.

[^23]:    *Nonpolar molecular solids are arranged in order of increasing molar mass. Note the correlation with increasing melting point (mp).

[^24]:    *Francium is so rare (estimates indicate only 15 g of the element in the top kilometer of Earth's crust) that its properties are largely unknown. Therefore, we will mention it only occasionally in the discussion.
    ${ }^{\dagger}$ Throughout the chapter, we use E to represent any element in a group.

[^25]:    Magnet levitated by superconductor

[^26]:    *Experimentally determined value.

[^27]:    *This equation and equilibrium expression are sometimes referred to as a hydrolysis reaction and a hydrolysis constant, $K_{\mathrm{h}}$, because water is dissociated (hydrolyzed), and its parts end up in the products. Actually, except for the charge on the base, this process is the same as the protonabstraction process with molecular bases such as ammonia, so a new term and equilibrium constant are unnecessary. That is, $K_{\mathrm{h}}$ is just another symbol for $K_{\mathrm{b}}$, so we'll use $K_{\mathrm{b}}$ throughout.

[^28]:    *Actually, bond energy refers to bond breakage that forms an H atom, whereas acidity refers to bond breakage that forms an $\mathrm{H}^{+}$ion, so the two processes are not the same. Nevertheless, the magnitudes of the two types of bond breakage parallel each other.

[^29]:    *In acid-base titrations, volumes and concentrations are usually known to four significant figures, but pH is generally reported to no more than two digits to the right of the decimal point.

[^30]:    *Any modern statement of conservation of energy must take into account mass-energy equivalence and the processes in stars, which convert enormous amounts of matter into energy. These can be included by stating that the total mass-energy of the universe is constant.

[^31]:    *An $S^{\circ}$ value for a hydrated ion can be negative because it is relative to the $S^{\circ}$ value for the hydrated proton, $\mathrm{H}^{+}(a q)$, which is assigned a value of 0 . In other words, $\mathrm{Al}^{3+}(a q)$ has a lower entropy than $\mathrm{H}^{+}(\mathrm{aq})$.

[^32]:    *The current required to operate modern digital voltmeters makes a negligible difference in the value of $E_{\text {cell }}^{\circ}$.

[^33]:    *Recall from Chapter 20 that only a reversible process can do maximum work. For no current to flow and the process to be reversible, $E_{\text {cell }}$ must be opposed by an equal potential in the measuring circuit: if the opposing potential is infinitesimally smaller, the cell reaction goes forward; if it is infinitesimally larger, the reaction goes backward.

[^34]:    *The most important orbital occupancies are in color

[^35]:    *Most common states in boldface.

[^36]:    *Note the distinction between the hybrid-orbital designation here and that for octahedral molecules like $\mathrm{SF}_{6}$. The designation gives the orbitals in energy order within a given $n$ value. In the $\left[\mathrm{Cr}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ complex ion, the $d$ orbitals have a lower $n$ value than the $s$ and $p$ orbitals, so the hybrid orbitals are $d^{2} s p^{3}$. For the orbitals in $\mathrm{SF}_{6}$, the $d$ orbitals have the same $n$ value as the $s$ and $p$, so the hybrid orbitals are $s p^{3} d^{2}$.

[^37]:    *Cosmic ray intensity does vary slightly with time, which affects the amount of atmospheric ${ }^{14} \mathrm{C}$. From ${ }^{14} \mathrm{C}$ activity in ancient trees, we know the amount fell slightly about 3000 years ago to current levels. Recently, nuclear testing and fossil fuel combustion have also altered the fraction of ${ }^{14} \mathrm{C}$ slightly. Taking these factors into account improves the accuracy of the dating method.

[^38]:    *Although this statement is generally correct, differences in isotopic mass can influence bond strengths and therefore reaction rates. Such behavior is called a kinetic isotope effect and is particularly important for isotopes of hydrogen- ${ }^{1} \mathrm{H},{ }^{2} \mathrm{H}$, and ${ }^{3} \mathrm{H}$ —because their masses differ by such large proportions. Section 22.4 discussed how the kinetic isotope effect is employed in the industrial production of heavy water, $\mathrm{D}_{2} \mathrm{O}$.

[^39]:    *For an excellent scientific and historical account of the development of the atomic bomb, see R. Rhodes, The Making of the Atomic Bomb, New York, Simon and Schuster, 1986.

[^40]:    *An even greater release of radioactivity ( 1.1 MCi ), involving several radionuclides including the extremely dangerous ${ }^{90} \mathrm{Sr}$, occurred in 1957 in Kyshtym, a town in the South Ural Mountains of Russia. As a result, radioactivity spread globally, but the accident was kept secret by the former Soviet government until 1980.

[^41]:    *All values at 298 K, except for acetylsalicylic acid.
    ${ }^{\dagger}$ Acidic (ionizable) proton(s) shown in red. Structures shown have lowest formal charges.
    ${ }^{\dagger \dagger}$ At $37^{\circ} \mathrm{C}$ in 0.15 M NaCl .

[^42]:    ${ }^{\dagger}$ Blue type indicates the basic nitrogen and its lone pair.

[^43]:    *All values at 298 K . Written as reductions; $E^{\circ}$ value refers to all components in their standard states: 1 M for dissolved species; 1 atm pressure for the gas behaving ideally; the pure substance for solids and liquids.
